SUPPLEMENT TO Industries, 10TH JULY, 1891.

Industries:

A JOURNAL OF ENGINEERING, ELECTRICITY, & CHEMISTRY

FOR THE

Mechanical and Manufacturing Trades.

VOL. X.—JANUARY TO JUNE, 1891.

Offices:

358, STRAND, LONDON, W.C.

INDEX TO "INDUSTRIES."

Articles.

*(All Articles marked thus * are Illustrated.)*

"Abt" Locomotive, The, 272*
Ackroyd-Willoughby Smoke Preventer and Fuel Economiser, The, 460*
"Acme" Pliers, The, 221*
Aerial Ropeway, The Garrucha, 577*, 603*
Agricultural Prospects of Canada, The, 315
Agricultural Show, The Bath and West of England, 564
Agricultural Show, The Royal, 592*, 608*
Air Compressors for H.M.S. "Royal Arthur," Quadruple, 536*
Air of Large Cities, The Analysis of the, 91
Air Thermometer for Technical Purposes, A New Form of, 139*
Alkali Trade, The Present Position of the, 158
Alkali Works Report, The, 614
Allen & Robson's Magnolia-lined Bearing Pedestals, 472*
Alloys, Notes on, 235, 475
Alternating Current Flow in Circuits having Capacity and Self-Induction, Some Effects of, Abstract of a Paper read by Dr. J. A. Fleming before the Institution of Electrical Engineers, 451
Alternating Currents of High Frequency, Tesla's Experiments with, Abstract of a Paper read by Mr. Nikola Tesla before the American Institute of Electrical Engineers, 546, 571
Aluminium and Steel, 230
America and the Silver Question, 86
America, The Iron and Steel Industries of, 469
American Industries, The Investment of English Capital in, 37
American Institute of Electrical Engineers, The, 546, 570, 571, 594
American Iron and Steel Industries, German Impressions of, 147
American Iron and Steel Production in 1890, 529
American Locomotive for the Japanese Government Railways, An, 148*
American Mail Service, 444
American Mercantile Marine, The Decline of the, 146
American National Electric Light Association, The, 257
American Patent System, Centenary of the, 303
American Patent System, The, 536*
American Postal Subsidy and Shipbuilding, The, 278
"Amidon" Corner Brace, The, 252*
Analysts' Qualifications, 139
Analytical Chemist and the Institute of Chemistry, The, 494
Antiseptic Compounds, Organic, 115
Arbey's Improved Forestry Machinery, 29*
"Argus" Cloth Stamping Machine, The, 560*
Armstrong, Mitchell, & Co.'s Exhibits at the Royal Naval Exhibition, 436*, 488*
Artillery, On Tests for Steel Used in the Manufacture of, Paper read by Dr. W. Anderson, M.Inst.C.E., before the Iron and Steel Institute, 531, 554
Arts and Crafts at the Glasgow East End Exhibition, 385
Atlantic Liner on Fire, An, 592
Atlantic Race, The, 389, 543
Australia and Trade, 398
Australia, The New Route to, 159
Australian Railways, The Brake Question on South, 374

"Backus" Gas Engine, The, 388*
Barnes Water Emery Grinder, The, 128*
Bath and West of England Agricultural Show, The, 564
Battery Zincs, Improved, 593*
Battleship "Renown," The New, 446
Bazalgette, The Late Sir Joseph, 279
Bearing, Experiments on the Friction of a Pivot, 386*
Bearing for Propeller Shafts, Thrust, 485*
Beeswax and Its Purification, 236
Belgium, The Manufacture of Cement in, 36*
Belliss & Co.'s Exhibit at the Royal Naval Exhibition, Messrs. G. E., 605*
Bell's Apparatus for Drying Clay and Mineral Earths, 171*
Bentley's Quick-Return Slotting Machine, 433*
Bentz Process) (The, An Improved Bleaching Apparatus, 56*
Berend's Measurer, 290*
Bevelled Timber, Sawing Machines for, 146*
Bicycle, Roberts' Spring Frame Safety, 152*
Birmingham, Proposed New Water Supply for, 377
Blackpool Eiffel Tower, The, 593*
Bleaching Apparatus, An Improved (The Bentz Process), 56*
Bleaching Process, The Hermite Electro-, 138*
Blind, Cockburn's Type-Writer for the, 449*
Blower, Skinner's Improved, 18*
Boat, An Improved Unsinkable Self-Righting, 617*
Boiler, Carson's Improved Marine, 290*
Boiler Construction Suitable for Withstanding the Strains of Forced Draught, so far as it affects the Leakage of Boiler Tubes, by Mr. A. F. Yarrow, before the Institution of Naval Architects, 337*
Boiler Deposits, 518
Boiler Deposits, Paper read by Professor Vivian B. Lewes before the Institution of Naval Architects, 363, 386
Boiler Explosion at Jarrow, Formal Inquiry into the, 80
Boiler Explosion at the Haybridge Ironworks, 8
Boiler Explosions, Graphical View of the Causes of, 242*
Boiler Flue Flange Drilling Machine, Booth's, 128*
Boiler Flue Flanging Machine, Booth's, 84*
Boiler for Torpedo Boats, Improved Water-Tube, 60*
Boiler Inspection and Registration Bill, The, 375
Boiler Pressure and Piston Speed for Marine Engines, Increased, Paper read by Mr. Wm. Russell Cummins before the North East Coast Institution of Engineers and Shipbuilders, 51*
Boiler Shells, The Stresses in, 433*
Boiler, The "Stanley," 512*
Boilers for Submarine Vessels, Oil-fired, 315*
Boilers, Results of Experiments on the Strength of, Paper read by Mr. J. C. Spence before the North East Coast Institution of Engineers and Shipbuilders, 242*, 266*
Bolton's Non-Conducting Material, 353*
Booth's Boiler Flue Flange Drilling Machine, 128*
Booth's Boiler Flue Flanging Machine, 84*
Borax, The Preparation and Industrial Application of, 90*
Boring Machine for Taper Holes, Improved, 145*
Boring Stand, Sagar's, 464*
Bott's System of Pneumatic Guns and Projectiles, 616
Boy Messengers, The Post Office and the, 398
Brace, The "Amidon" Corner, 252*
Brake Question on South Australian Railways, The, 374
Bridge at Glasgow, The New Dalmarnock, 412*
Bridge, Shaw's "Pneumatic," 485*
Britannia Company's Quick-Running Drilling Machine, 296*
British Tanning Company v. Groth, 88
British Warships, New, 200
Brooks, The Late Mr. David, 591*
Bryce-Douglas, The Late Mr., 350
Budget, Mr. Goschen's, 421
Building Materials, Iron and Steel Considered as, 76
Building of the Ship," "The, 518
Bulkheads Committee, Report of the, 613
Burner, The Improved "Wigham," 508*
Burton, The Late Mr. Cosmo Innes, 87

Calliper, A Beam Micrometer, 304*
Canada, The Agricultural Prospects of, 315
Canal, Japan, The Kioto, 65*
Canal, The Manchester Ship, 16, 28, 184*, 230, 231*, 272*, 364*
Canal, The Nicaragua, 289*, 361*, 420, 481*, 532*, 556*
Canal, The Panama, 422
Canal, The Proposed Forth and Clyde Ship, 254, 398
Carlaw's Improved Envelope Folding Machine, 104*
Carpenter, The Late Mr. Lant, 15
Carson's Improved Marine Boiler, 290*
Cells, Setting up Standard, 594*
Celluloid and its Manufacture, 571
Cement, A New Method of Testing Portland, 98
Cement in Belgium, The Manufacture of, 36*
Cement Specifications, Portland, 553
Census and Large Towns, The Recent, 567
Central Stations, Cost of, 350
Channel Bridge, The Proposed, 16
Channel Tubular Railway, The, 268
Charles' Dynamo Brush Holder, 545*
Chelsea System of Electrical Distribution, The, Abstract of a Paper read before the Institution of Electrical Engineers by Major-General Webber, 162.
Chemical Equivalents, Mechanical and, Abstract of Paper read by Mr. G. B. Ellis before the Institute of Patent Agents, 75
Chemical Industry in 1890, The Progress of, 43
Chemical Industry, Society of—London Section, 42, 91, 139, 188, 284, 355, 404, 451, 547; Liverpool Section, 259, 356, 499; Manchester Section, 92, 187, 260, 355, 475, 619
Chemical Society, The "Jubilee" of the, 116, 206
Chemist and the Institute of Chemistry, The Analytical, 494
Chemistry in its Relation to Sanitation, Modern, 259, 283, 308
Chemistry, The Institute of, 163, 186, 472 494
Chicago Exhibition, The, 38, 569*, 601
Chignecto Ship Railway, The, 97*, 121* (see also "Notes," 164, 476)
Chlorine, The "Donald" Process for the Manufacture of, 380
"City of Paris," The, 446
"City of Perth," Triple-Expansion Engines of the, 63*
Civil Engineers, The Institution of (see Engineers, The Institution of Civil)
Clarke, Chapman, & Co.'s Combined Engine and Dynamo, 497*
Clay and Mineral Earths, Bell's Apparatus for Drying, 171*
Cleveland Institution of Engineers, The, 80, 208
Cloth Stamping Machine, The "Argus," 560*
"Clyde" Piston Ring, The, 315*
Clyde Shipbuilding, 152, 254, 368, 468, 560
Clyde Ship Canal, The Proposed Forth and, 254, 398
Coal Dust in Mines, 36, 159
Coal, Iron, and Cognate Industries, 63, 374, 470
Cockburn's Type-Writer for the Blind, 449*
Coinage During the Year 1890, The, 542
Colour Stamping Machine, Relief, 409*
Commerce During 1890, Industries and, 1
Commerce, The Navy and British, 254
Commercial Museum, The Japanese, 457*
Commission, The Labour, 206, 373, 542
Communication with the East, Improved, 446
Compounds, Organic, Antiseptic, 115
Concentrator, The "Garnier" Ore, 5*
Conciliation, Manchester Joint Board of, 303
Congress, An Immense, 601
Constructions in Earthquake Countries, 123
Continental Labour, 446
Cooper's Hill College, 566
Cooper's Lead Pipe Joint, 76*
Copenhagen, The Projected Free Harbour at, 49*
Copper and Diameter in Gramme Machines, The Relation between Weight of, 617*
Copper Depositing Process, The Elmore, 112 210*
Copper, The Annealing of, 388
Corliss Mill Engine, Powerful, 76*
Cornell University, 566
Cornell University, The Engineering School, 101
Cotton Industry, The, 14
Crane, Smith's Overhead Steam Travelling, 172*
Cranes, Electric, 378
Crompton-Chandler Steam Dynamo, The, 324*
Cunard Steamers, New, 230
Cunliffe & Croom's Milling Machine, 200*
Currency Proposals, Mr. Goschen's, 325
Current Flow in Circuits having Capacity and Self-Induction, Some Effects of Alternating, Abstract of a Paper read by Dr. J. A. Fleming before the Institution of Electrical Engineers, 451

"Daimler" Gas and Petroleum Motor, The, 162*
Dakota, The Tin Deposits of South, 532
Dalmarnock Bridge at Glasgow, The New 412*
Davies' Machine for Cleaning Tinplates, 554*

19995

Digitized by Google

Decimal Coinage, Weights, and Measures, 221, 615
Decimal System, Postal Reform and the, 470
Defiance Machine Works' Automatic Wheel Boxing Machine, 584*
Demography, Seventh International Congress of Hygiene and, 542
"Demon" Cold Iron Saw, The, 169*
"Demon" Water Motor, The, 531*
Deptford Mains, The Phenomena of the, 39, 63*
Detroit Motor Company's New Electric Hoist, 281*
Dixon's Ironworks, Glasgow, Explosion at, 254
Dixon, The Late Mr. John, 134
"Donald" Process for the Manufacture of Chlorine, The, 380
Drill, A New Twist, 305*
Drill Machinery, Milling Cutter and Twist, 265*
Drill, New Type of Marvin Electric, 18*
Drilling Machine, Booth's Boiler Flue Flange, 128*
Drilling Machine, Quick-Running, 296*
Drying Clay and Mineral Earths, Apparatus for, 171*
Dublin Loop Line, The, 201*
Dumbartonshire, Proposed New Railways in, 615
Duncan Stewart & Co.'s Rolling Mill Engines, 392*
Dunlop's Radial Reversing Valve Gear, 505*
Dutch Government Warship "Prinses Wilhelmina," The, 193*
Dutch Royal Steam Packet Company's Steamer "Van Goens," The, 505*
Dwight Metal Marking Machine, The, 193*
Dynamite Gun, The Graydon, 104
Dynamo Brush Holder, Charles', 545*
Dynamo Brushes, 38
Dynamo, Combined Engine and, 497*
Dynamo, Holmes' Train Lighting, 473*
Dynamo, Siemens', 401*
Dynamo, The Crompton-Chandler Steam, 324*
Dynamo, The "Kingdon" Inductor, 252*
Dynamos, Foucault Currents in, 450
Dynamos, Notes on the Design of Multipolar, Abstract of a Paper read by Mr. W. B. Esson before the Institution of Electrical Engineers, 354, 378*

Earthquake Countries, Constructions in, 123
East, Improved Communication with the, 446
Eddystone Lighthouse Model at the Royal Naval Exhibition, The, 344*
Education, Technical, 182
Egner's Elliptograph, 248*
Egypt, The Sugar Industry in, 409
"Eickemeyer" Street Railway Motor, 114*
Eight Hours Bill, The, 159
Electric Cranes, 378
Electric Drill, New Type of Marvin, 18*
Electric Hoist, A New, 281*
Electric Light Association, The American National, 257
Electric Lighting in Hampstead, 354
Electric Lighting of the City of London, 134
Electric Lighting Plant at the Royal Naval Exhibition, 580*
Electric Lighting Plant of the Metropolitan Police Offices, The, 425*
Electric Lighting Purposes, Triple-Expansion Engine for, 509*
Electric Organs, 569*
Electric Pinnace, An, 448
Electric Power by Means of a Voltmeter, Measurement of, 306*
Electric Stations, Cost of Central, 350
Electric Transmission of Power, The. Abstract of Cantor Lecture delivered at the Society of Arts by Mr. Gisbert Kapp, M.Inst.C.E., 185, 209, 234
Electrical Distribution, The Chelsea System of, Abstract of a Paper read before the Institution of Electrical Engineers by Major-General Webber, 162
Electrical Engineering in 1890, The Progress of, 41, 65
Electrical Engineers, American Institute of, 546, 570, 571, 594
Electrical Engineers, The Institution of (see Engineers, The Institution of Electrical)
Electrical Exhibition, The Frankfort, 474*
Electrical Exhibition, The St. Pancras, 281
Electrical Section of the London Chamber of Commerce, 110
Electrical Standards, 162
Electricity in Transitu: From Plenum to Vacuum, Abstract of Presidential Address given by Mr. Wm. Crookes, F.R.S., before the Institution of Electrical Engineers, 88*, 114*, 138*
Electricity Meters, The Ferranti, 257*
Electro-magnetic Gas Controller, 617*
Elliptograph, A Simple, 248*
Elmore Copper Depositing Process, The, 112, 210*
Emery Grinder, The Barnes Water, 128*
Emery Grinding Machine, The "Universal," 32*
E.M.F. of Simple Voltaic Cells, The Calculation of the, 233
Engine and Dynamo, Combined, 497*
Engine for Electric Lighting Purposes, Triple-Expansion, 509*
Engine Governors, Steam, Paper read by Mr. C. F. Budenberg, M.Sc., before the Manchester Association of Engineers, 392*, 410*, 435*, 459*
Engine Indicator, The "Perry," 516*
Engine, Powerful Corliss Mill, 76*
Engine, Ross & Duncan's Triple-Expansion Mill, 105*
Engine, The "Backus" Gas, 388*
Engines in the Navy, 302
Engines of the S.S. "City of Perth," Triple-Expansion, 63*
Engines, Rolling Mill, 392*
Engines, Wild's Portable Hauling and Winding, 73*
Engineering Progress in 1890, 25
Engineering School, Cornell University, The, 101
Engineers and Naval Architects, Hull Institution of, 171, 265
Engineers in Japan, The Institution of, 39
Engineers in the Royal Navy, 293
Engineers, Leeds Association of, 248, 272, 464
Engineers, Society of, 128, 218, 364, 444
Engineers, The American Institute of Electrical, 546, 570, 571, 594
Engineers, The Cleveland Institution of, 80, 208
Engineers, The Education of, 133
Engineers, The Federated Institution of Mining, 536
Engineers, The Institution of Civil, 38, 73, 122, 145, 232, 320, 348, 471, 593
Engineers, The Institution of Electrical, 88*, 114*, 138*, 162, 176*, 209*, 224*, 234, 281, 354, 378*, 402, 425, 451, 497, 522, 524, 545
Engineers, The Institution of Marine, 81, 125, 176, 220, 248, 272, 345, 368
Engineers, The Institution of Mechanical, 124, 267*, 305, 313, 386*, 440*, 448*, 457, 483*, 506*
Engineers, The Manchester Association of, 392*, 410*, 435*, 459*
Engineers, The University Training of, Abstract of an Introductory Lecture delivered at Cambridge by Professor J. A. Ewing, F.R.S., 170, 194
English Capital in American Industries, The Investment of, 37
Envelope Folding Machine, Improved, 104*
Equivalents, Mechanical and Chemical, Abstract of Paper read by Mr. G. B. Ellis before the Institute of Patent Agents, 75
Evaporator as Fitted in the S.S. "Damascus," Kirk's, 100*
Exhibition, Arts and Crafts at the Glasgow East End, 385
Exhibition at Moscow, 1891, The French, 5*
Exhibition, The Chicago, 38, 569*, 601
Exhibition, The Frankfort Electrical, 474*
Exhibition, The German, 470, 518
Exhibition, The Palermo, 172, 386*
Exhibition, The Printing, Stationery, and Kindred Trades', 304, 353*, 409*
Exhibition, The Royal Naval, 217*, 344*, 423, 424*, 436*, 488*, 497*, 536*, 580*, 605*
Exhibition, The St. Pancras Electrical, 281
Explosion at Dixon's Ironworks, Glasgow, 254
Explosion at Jarrow, Formal Inquiry into the Boiler, 80
Explosion at the Haybridge Ironworks, The Boiler, 8
Explosions, Graphical View of the Causes of Boiler, 242*
Explosives, The Relative Strengths of High, 19
Extractor, Merz's Universal, 403

Fairfield Shipbuilding and Engineering Company, The, 518
Faraday Centenary Lecture, The, 590
Feed-Water Heater and Circulator, The "Pyros," 269*
Ferranti Electricity Meters, The, 257*
Fiège's "Demon" Cold Iron Saw, 169*
Flanging Machine, Booth's Boiler Flue, 84*
Forestry Machinery, Arbey's Improved, 29*
Forth and Clyde Ship Canal, The Proposed, 254, 398
Fortunes and Land Purchase, Commercial, 84
Foucault Currents in Dynamos, 450
Foundations and Other Works, Timber Piling in, 470
Fraissinet's Oil-fired Boilers for Submarine Vessels, 315*
Frankfort Electrical Exhibition, The, 474*
Friction of a Pivot Bearing, Experiments on the, 386*
Fuel Economiser, The Ackroyd-Willoughby Smoke Preventer and, 460*

"Garnier" Ore Concentrator, The, 5*
Garrucha Aerial Ropeway, The, 577*, 603*
Gas Controller, Electro-magnetic, 617*
Gas and Petroleum Motor, The "Daimler," 162*
Gas Engine, The "Backus," 388*
Gas Engine, The "Simplex," 18
Gas, Petroleum and Natural, 464
German Exhibition, The, 470, 518
German Impressions of American Iron and Steel Industries, 147
Germany, Patent Law in, 400
Glasgow East End Exhibition, Arts and Crafts at the, 385
Glasgow, The New Dalmarnock Bridge at, 412*
"Goolden" Mining Motor, The, 89*
Governors, Steam Engine, Paper read by Mr. C. F. Budenberg, M.Sc., before the Manchester Association of Engineers, 392*, 410*, 435*, 459*
Graham Twist Drill Company's New Twist Drill, 305*
Gramme Machines, The Relation between Weight of Copper and Diameter in, 617*
Graydon Dynamite Gun, The, 104
Greases, Lubricating Oils and, 115
Greenlee's "Universal" Sheet Metal Cutting Machine, 171*
Grinder, The Barnes Water Emery, 128*
Gumming Machine, Pellatt's, 409*
Gunboats, The "Sharpshooter" Class of Torpedo, 169, 278
Gun, Irvine's Pneumatic Line-Throwing, 424*
Gun, The Graydon Dynamite, 104
Guns and Projectiles, Pneumatic, 616

Hampstead, Electric Lighting in, 354
Harbour at Copenhagen, The Projected Free, 49*
"Harlow" Sight-Feed Lubricator, The, 329*
Harrild's Paper Cutting Machine, 588*
Haussmann, The Late Baron, 87
Hawkshaw, The Late Sir John, 542
Haybridge Iron Works, Boiler Explosion at, 8
Helix-forming Machine, Improved, 601*
Hermite Electro-Bleaching Process, The, 138*
Highland Railway, The West, 12*, 241*
Hines & Robertson's Planimeter, 152*
Hoist, A New Electric, 281*
Hoisting Plant for H.M.S. "Vulcan," Hydraulic, 99
Holmes' Train Lighting Dynamo, 473*
Howe's "Little Giant" Turbine, 505*
Hull Institution of Engineers and Naval Architects, The, 171, 265
Hulse's Milling Cutter and Twist Drill Machinery, 265*
Hydraulic Hoisting Plant for H.M.S. "Vulcan," 99
Hydrochloric Acid from Waste Products, The Recovery of, 163*
Hygiene and Demography, Seventh International Congress of, 542
Hysteresis, Note on the Law of, 19*

India, Progress in, 566
Indiarubber "Ring," The Proposed, 110
Indicator, Simpson's Train, 385*
Indicator, The "Perry" Engine, 516*
"Indispensable" Lathe Dog, The, 392*
Industrial Outlook for 1891, The, 13
Industries and Commerce during 1890, 1
Industries, German Impressions of American Iron and Steel, 147
Industry and Labour, The Future of, 397
Inflammable Liquids Bill, The, 278, 374
Institute of Chemistry, The, 163, 186, 472, 494
Insulation of Overhead Wires, The, 302
Insurance for Seamen, The Shipping Federation, 374
Insurance of Scotch Miners, 350
Invention, Patent Fees and their Effect upon, 61
Ireland, Introduction of the Zone Railway System into, 393
Iron, and Cognate Industries, Coal, 63, 374, 470
Iron and Steel Considered as Building Materials, 76
Iron and Steel Industries of America, The, 469
Iron and Steel Industry, The Russian, 553
Iron and Steel Institute, The, 448, 464, 531, 555, 556, 578, 604*
Iron and Steel Production in 1890, American, 529
Iron and Steel Production in the United States and Great Britain, 220*
Iron Produced by Thermal Treatment, On the Changes in, Paper read by Mr. E. J. Ball, Ph.D., before the Iron and Steel Institute, 604*
Irvine's Pneumatic Line-Throwing Gun, 424*

Japan, A Japanese View of New, 182
Japan, The Institution of Engineers in, 39
Japan, Treaty Revision in, 86
Japanese Commercial Museum, The, 457*
Japanese Foreign Treaties, 134
Japanese Government Railways, An American Locomotive for the, 148*
Jarrow, Formal Inquiry into the Boiler Explosion at, 80
Jenkins, The Late Professor, 591
John, The Late Mr. William, 15

Keely on Latent Force, Mr., 492
Kilner & Matthew's System of Deep Well Pumping, 121
"Kingdon" Inductor Dynamo, The, 252*
Kioto Canal, Japan, The, 65*
Kirk's Evaporator as Fitted in the S.S. "Damascus," 100*

Labour Commission, The, 206, 373, 542
Labour, Continental, 446
Labour, The Tendencies and Prospects of, 157
Labour, Workmen's Hours of, 326
Lactic Acid, The Manufacture of, 500
Laidlaw's Improved Helix-forming Machine, 601*
Lamp, Steuth's Regenerative Gas, 235*
Land Purchase, Commercial Fortunes and, 84
Latent Force, Mr. Keely on, 492
Lathe Attachment, An Improved, 272*
Lathe, Boring and Chuck, 248*
Lathe Dog, The "Indispensable," 392*
Lathe, Improved Brass Finishers' Turret, 221*
Lathe, Ornamental Turning, 361*
Lathe, Small Screw Cutting, 553*
Lead Pipe Joint, Cooper's, 76*
Leeds Association of Engineers, 248, 272, 464
Legal Proceedings, 88, 112, 256, 304, 376, 518
Leland, Faulconer, & Norton Company's New Tool Grinder, 420*
Lifeboat for Pwllheli, Steel Tubular, 481*
Life-Saving Apparatus, 145
Lighthouse Burner, The Improved "Wigham," 508*
Lighthouse Illuminants, 400
Lighthouses, Telegraphic Communication with, 615
Line-Throwing Gun, Irvine's Pneumatic, 424*
Lister's Small Screw Cutting Lathe, 553*
"Little Giant" Turbine, The, 505*
Locomotive for the Japanese Government Railways, An American, 148*
Locomotive for the St. Gothard Railway, Duplex-Compound, 444*
Locomotive, The "Abt," 272*
Locomotive Tyres, Irregular Wear of, Paper read by Mr. J. N. Barr before the American Western Railway Club, 219*
Locomotives, Improved Sand Drier for, 224*
Locomotives, Petroleum as Fuel in, 533
Log Sawing Machine, Steam Power, 152*
London Chamber of Commerce, The Electrical Section of the, 110
London, Electric Lighting of the City of, 134
London-Paris Telephone, The, 280
London Smoke and Fog Plague: Its Origin and Dangers, and a Proposed Solution for Its Remedy, 41, 66*

Industries.

INDUSTRIES AND COMMERCE DURING 1890.

ALTHOUGH the prospects that appear to be in the immediate future are not, perhaps, quite so roseate as those of a year ago, yet it is hardly possible to claim that the trade of the year 1890 has been unsatisfactory. The amount of business done during last year by manufacturers and merchants has probably been fully equal to that done in any previous year, and has been much more satisfactory than that done in any recent year if we except the year 1889. The condition of trade has not, however, been so steady, nor has the prosperity of its different branches been so uniform, as in that year. Some departments have been enjoying an almost bounding prosperity, while others have been more or less depressed; but the great index to the actual average of the whole—the Board of Trade returns of exports—show that for the first eleven months of 1890—which is the period uniformly dealt with throughout this review, inasmuch as the full returns for the year are not available at the date of writing—there was an increased business to the extent of over fourteen millions sterling, as compared with the corresponding period of the previous year. While this is satisfactory, as far as it goes, it is not so to find that in the month of November our exports declined to the extent of nearly a million and a quarter; nor is it in some respects a matter for satisfaction that our imports have decreased to the extent of over eight millions sterling in the eleven months. It is, of course, possible that this has been a decline of prices rather than of volume, and if this were so it would be a matter for sincere congratulation. It is, however, all but impossible to estimate the volume of our imports, apart from their value, as they are expressed in terms that do not admit of comparison. Similarly, it is possible that the increase shown in the value of our exports is an increase of price rather than of volume, in which case the amount of work turned out, and consequently the amount of labour provided, would not be so great as the figures on the first inspection would suggest.

AGRICULTURAL INDUSTRY.

The condition of the agricultural interests of Great Britain appears to have considerably improved during the last two years, due partly to the better harvests, partly to the changes in the system of cropping (and especially the growing on a larger scale of vegetables, fruits, &c.), and partly to the increased demand for British produce at higher prices, rather than for foreign produce at lower ones. This last-named fact is, of course, only another way of stating that the purchasing power of the general community has been improved, so that they have been able more largely to buy British beef and mutton, where they had previously to buy foreign, and so with other articles in daily consumption.

The agricultural returns for the year 1890, which have recently been issued by the Agricultural Department, show that the total area of land under wheat crops in Great Britain in that year was 2,386,336, as compared with 2,449,000 acres in the previous year; of barley, the area under crops was 2,111,178, as compared with 2,121,530 in the previous year; and of oats the area was 2,902,998, as compared with 2,888,704 acres. The average yield per acre was for wheat, 30·74 bushels, against 29·89: of barley, 35·02, against 31·78; and of oats, 41·40, against 39·27 bushels. On the whole, therefore, the harvest has been a good one—considerably better than the average, as regards all three crops. There has, moreover, been a large increase in 1890 in the number of cattle and sheep in Great Britain. There is a diminished return in the statistics of the land under hop and beet crops, but there has been a larger area under small fruit, such as strawberries, currants, gooseberries, &c. It may be added that "the record of live stock in Great Britain in 1890 is the most satisfactory presented for many years."

So far as the second great branch of our agricultural industry is concerned—that of the distribution of imported foreign produce—the following table shows the quantities and the values of our imports for 1890, compared with the previous year:—

Imports of Agricultural Produce into the United Kingdom in 1889 and 1890.

	Imports. 1 = 1,000 Cwt. 1889.	1890.	Value. £1 = £1,000. 1889.	1890.	Average Value per Cwt. 1889. £ s. d.	1890. £ s. d.
Cereals:						
Wheat	53,623	55,185	20,629	21,274	0 7 8¼	0 7 8½
Wheat meal and flour	13,143	14,318	7,652	8,202	0 11 7½	0 11 5½
Barley	15,955	14,807	4,533	4,407	0 5 8¾	0 5 11½

Fresh mutton	1,177	1,535	2,367	3,199	2 0 2½	2 1 8
Salted pork	240	223	364	298	1 10 4	1 6 8½
Fresh pork	112	35	273	86	2 8 9	2 9 1½
Butter	1,759	1,852	9,310	9,630	5 5 10	5 3 11
Cheese	1,776	1,967	4,155	4,558	2 6 8	2 6 3
Rabbits	105	119	274	331	2 12 2	2 16 6
Totals	11,352	12,996	30,367	33,042	—	—

Of the total quantities of articles of food consumption received during 1890, the following proportions were received from the United States:—

	1890. Quantity. 1=1,000 Cwt.	Value. £1=1,000.	1889. Quantity. 1=1,000 Cwt.	Value. £1=1,000.
Wheat	15,681	6,262	15,330	6,149
Flour	11,025	6,148	8,912	5,016
Bacon	2,632	4,392	2,245	4,270
Salted beef	239	325	226	312
Fresh beef	1,545	3,308	1,153	2,556
Hams	1,009	2,378	798	2,032
Other meat	15	29	19	41
Pork, salted	174	240	175	263
Butter	80	305	98	401
Cheese	834	1,888	770	1,757
Cured fish	203	565	247	752
Lard	1,085	1,792	1,021	1,870
Totals	34,522	27,632	30,994	25,419

On comparing the two preceding tables, it will be noted that while the imports of cereals have increased in 1890 by some 5 millions of cwt., and those of other foods by about 1½ million cwt., there has been an increase of only about a million and a half in our imports from the United States. This would appear to show that we are not now depending upon the United States so entirely as we formerly did.

IRON AND STEEL.

The year 1890 has, on the whole, been fairly favourable for the iron and steel industries. There has been a considerable increase in the production of pig iron, the make for the first half of the year having been 4,168,464 tons, or about 85,000 tons more than the production for the first half of the previous year. The most marked feature of the year's business has, however, been the reduction of stocks, which now stand at about 590,000 tons, as compared with 1,030,000 tons at the same period of 1888. The furnaces in blast in Scotland at the latter part of the year were reduced to six in consequence of the labour troubles that occurred about that time, so that it is estimated that between the 6th of October and the 20th of December there was a reduction of 200,000 tons in the make, causing makers' yards to be completely cleared of stocks, and a reduction of 47,000 tons in the public stores. The immediate effect of the strike was to cause the Scotch ironmasters to blow out seventy-two furnaces, so that during the last three months of the year the trade has been in anything but a satisfactory state. Indeed, the only good thing that can be said about it is that the action of the trade has caused a reduction of stocks that may keep prices steadier in the time to come. The shipments of pig iron from Scotland during the year have been more than those of either 1888 or 1889, notwithstanding the reduction of make, and it is not a little remarkable that in spite of the diminished production, the diminished stocks, and the increased shipments, the price of warrants for the last few weeks has been exceptionally low, varying from 46s. to 47s. per ton, as compared with 57s. to 62s. at the same period of 1889. It is not expected that the makers of pig iron in Scotland will substantially alter the present situation until they can see their way to cheaper labour and cheaper raw materials, as these have for some time past been too high to admit of pig being made at a profit.

Meanwhile the position of affairs in Scotland tends to improve the prospects of the iron trade in Cleveland. In that district the make of pig iron for the first six months of 1890 exceeded by 43,019 tons the make for the corresponding half of 1889, and it is probable that the make for the second half of the year will be on at least as large a scale. The number of furnaces blowing during the second half of the year was the same as in the second half of 1889, and at the 1st of December last the total stocks in the district had been reduced to about 236,000 tons. In other districts the condition of the trade is fairly satisfactory.

In the steel trade prices have not kept up so well as could be desired, but production continues large. The total make of Bessemer steel and Siemens steel ingots for the first half of the year 1890 compares as follows with 1889:—

	1890. Tons.	1889. Tons.
Bessemer steel	1,055,280	1,048,256
Open-hearth steel	753,572	750,721
Totals	1,808,852	1,793,977

The production of Bessemer steel rails in the first half of 1890 was 510,459 tons, being an increase of 42,134 tons on the quantity produced in the first half of 1889. The demand for steel for shipbuilding purposes continues large, although not so much so as formerly. The production of plates and angles of open-hearth steel for the first half of the year is stated at 289,272 tons. There are now at work in the United Kingdom 241 acid and 23 basic open-hearth furnaces, while in the second half of the year 12 acid and 8 basic open-hearth furnaces were under construction. Several new open-hearth steel works are being proceeded with in Scotland.

Exports.—The total exports of iron and steel from the United Kingdom during the year 1890 compared unfavourably as regards quantity, but favourably as regards prices, with those of 1889, as the figures in the table at the head of the next column show.

In the following table, the total exports of iron and steel in each half of the year 1890 has been set forth, the quantities exported for December being taken as for November, and the totals for the second half and for the whole year being, therefore, subject to rectification to that extent. The fact that December has one more day than November must not be overlooked, but on the other hand, business is usually slacker about Christmas.

Digitized by Google

Total Exports of Iron and Steel from the United Kingdom during the First Eleven Months of 1890, *with total Official Value, and calculated Average Value per Ton, compared with* 1889. (1 = 1,000).

	Quantity.		Value.		Average Value per Ton in £'s and Decimals thereof.	
	1890. Tons.	1889. Tons.	1890. £	1889. £	1890. £	1889. £
Pig iron	1,089	1,116	3,335	2,729	3·0	2·4

Unworked steel	72	...	79	...	+ 7	...	151
Sundry steel and iron	14	...	11	...	− 3	...	25
Totals	2,019	...	2,016	...	− 3	...	4,035

In order to complete the information contained in this table, the values of the iron and steel exported during each half of 1890 have been treated in the same way in the following table, with the result that the total value of such exports, including steam engines and machinery, comes out as £52,306,000, a larger total than has ever before been realised in the history of the trade. It is satisfactory to find also that the value for the second half is greater than that for the first half of the year.

Statement Showing the Value of the Exports of Iron and Steel from the United Kingdom in each half of the Year 1890, *including Machinery and Steam Engines.*

	1890. First Half. 1=1000.		Second Half. 1=1000.		Increase (+) or Decrease (−) in Second Half.	
Pig iron	£1,875	...	£1,684	...	−	£191

Steam engines	2,178	...	3,240	...	+	1,062
Cutlery and tools	2,046	...	2,053	...	+	37
Machinery and millwork.	5,785	...	6,175	...	+	390
Grand total	25,940	...	26,366	...	+	426

During the year 1890 our principal customers have been:—For pig iron, Germany; for bar, angle, and bolt iron, India; for railroad iron, the Argentine; for wire, Australasia; for hoops, sheets, and plates, Australasia; for tinplates, the United States; and for other unenumerated iron, Australasia. It appears, therefore, that for three of the principal classes of exports Australasia has come prominently to the front. Canada makes a good second, having taken from us the following quantities as compared with Australasia and British India (1 = 1,000):—

	Canada.		Australasia.		India.		Total.
Pig iron	40	...	28	...	—	...	68
Bar and angle iron	9	...	33	...	46	...	88
Railroad iron	108	...	85	...	210	...	403
Hoops, sheets, &c.	15	...	61	...	54	...	130
Tinplates	15	...	6	...	—	...	21
Unenumerated iron	8	...	64	...	62	...	134
Unwrought steel	13	...	—	...	—	...	13
Totals	208	...	277	...	372	...	857

Although these figures are interesting, and probably complete, so far as they go, they are not intended to record the total exports of iron and steel to any of the three groups dealt with, the full details not being available until a much later date.

OTHER METALS THAN IRON AND STEEL.

The course of the copper trade during the year has been favourable. The quantity imported to the end of November was 3,912 tons less than the imports for the previous year, while the deliveries were 29,388 tons more. The price of copper has been tending steadily downwards for some time, and is now about £53 17s. 6d., as compared with £50 2s. 6d. at this time last year, and £85 three years ago. It is stated that as low grade copper ore escapes duty under the McKinley Act, the Rio Tinto Company have contracted to deliver over 200,000 tons of sulphur pyrites in the United States, from which, after the sulphur has been extracted for the manufacture of sulphuric acid, over 9,000 tons of fine copper will be obtained. This looks uncommonly like "carrying coals to Newcastle," considering that of the world's production of copper in 1889, amounting to over 350,000 tons, the United States produced about one-third. The stocks of copper in England and France at the end of November were estimated at 16,315 tons. The copper works at home and abroad are doing well at present prices, so that efforts are being made in many directions to obtain a larger output. The business done in wrought copper has not, however, been so large as that done in the more crude forms of the metal.

The following is a statement of the exports of other metals than iron and steel during each of the years 1890 and 1889:—

Metal.		Quantity Exported in 1890.	1889.		Value of Exports in 1890. £ = 1,000.	1889.
Lead	tons	50,851	49,292	...	742	714
Tin, unwrought	cwt.	93,368	100,196	...	459	481
Zinc or spelter	,,	149,829	124,659	...	147	95
Copper, unwrought	,,	805,141	562,345	...	2,337	1,327
,, wrought	,,	260,437	279,523	...	875	838
Mixed or yellow metal	,,	336,867	273,391	...	963	722
Brass	,,	96,635	96,797	...	457	437

It will be observed that in almost all of the metals tabulated there has been a better business done in 1890 than in the previous year. The principal exception is tin, of which the exports have diminished by nearly 7,000 cwt., but probably this is due to the maintenance of a comparatively high price as compared with that of the previous year. Lead, on the other hand, keeps pretty stationary, alike as regards the quantity exported and the prices received. The table that follows shows how average prices have varied during recent years:—

Average Prices of Exported Metals in Different Years.

Year.	Copper Ingots. Per Cwt.	Yellow Metal. Per Cwt.	Brass. Per Cwt.	Tin, Unworked. Per Cwt.	Zinc. Per Cwt.	Lead. Per Ton.
1875	£4·40	£3·91	£5·44	£4·57	23·82s.	£23·17
1880	3·41	3·02	4·24	4·52	16·77	17·41
1884	2·94	2·73	4·24	4·27	13·59	12·58
1888	3·88	3·30	4·90	5·81	15·68	14·99
1889	2·36	2·67	4·51	4·81	15·63	14·56
1890	2·90	2·86	4·73	4·92	19·60	14·55

TEXTILE INDUSTRIES.

The recent course of the cotton industry has been well epitomised in the statement that "our cotton spinners and manufacturers received a million and a quarter sterling less in money in 1889 than they did in 1885, although they gave in exchange for it an additional 37 million pounds of yarn and nearly a billion and a half of yards of cloth, and this, too, while the conditions of the competition with the foreigner necessitated the production of a finer and more expensive quality." It should be observed, on the other hand, that there has been a substantial decrease of the price of the raw material, the average import of which has fallen from £3·47 in 1873 to £2·94 in 1880 and £2·49 in 1886 (this being the minimum), while in 1889 the price rose again to £2·64, and in 1890 to £2·66 per cwt. The import of raw cotton into the United Kingdom in 1890 has been 13,657,000 cwt., as compared with 14,621,000 cwt. in 1889, and 12,810,000 in 1888. There has, therefore, been a less importation than in 1889, but a greater than in 1888. As shown above, the price paid for raw cotton in 1890 has been fractionally more than in 1889. On the other hand, the average export price of cotton yarn has been 11·5d. per pound, as compared with only 11·13d. in 1889, and 10·94d. in 1888.

During the last three months an interesting official return has been published, which throws a good deal of light on the recent condition of the cotton industry of the United Kingdom. The return, which has been compared with 1856, shows that between 1885, when the last similar return was published, and 1889, to which year the latest figures relate, there was a decrease of 276 in the number of cotton factories, but an increase of 578,000 in the number of spindles, of 49,000 in the number of looms, and of 50,000 in the total number of hands employed. As against this, the imports of raw cotton rose from 12,730,000 cwt. in 1885 to 17,299,000 cwt. in 1889, while the exports of cotton yarn rose from 246 million lb. to 252½ million lb., and the exports of cotton piece goods from 4,374½ millions to 5,001¼ millions of yards. Two facts are clearly established by these figures—the first, that there is a tendency to establish and work factories of larger dimensions than formerly; the second, that there has been a considerable increase in the quantity of work produced relatively to the number of looms, spindles, and hands employed. This is very satisfactory, as far as it goes, and proves that the cotton industry of the United Kingdom is as progressive as formerly, whatever may be the case as regards other countries.

WOOL AND WOOLLENS.

The total home consumption of wool in 1890 is stated at 665,000 bales, as compared with 701,000 bales for the corresponding month of 1889. The Continental consumption was 979,000 bales in 1890, and 927,000 bales in 1889, while the American consumption is estimated at 48,000 bales in 1890, and 67,000 bales in 1889. The net imports of wool into the London market for the five series of wool sales were equal to 1,178,000 bales, as compared with 1,236,000 bales for the corresponding series of 1889. There has been a diminished importation of wool from the Colonies and the River Plate States, but the Colonial supplies do not much differ from those of 1889.

The imports of sheep and lambs' wool in 1890 reached a total of 576 millions of lb., as compared with 655¾ millions of lb. in 1889, and 583⅓ millions of lb. in 1888. There was a diminished export of woollen yarns and tissues in 1890, the figures comparing as under with each of the two preceding years:—

Year.	Yarns. 1 = 1,000 lb.	Woollen Tissues. 1 = 1,000 yards.	Worsted Tissues. 1 = 1,000 yards.
1888	39,004	81,719	135,225
1889	41,700	68,279	156,767
1890	38,135	51,476	160,600

The diminution in the exportation of woollen tissues in 1890 is very noticeable, but over the same period there has been a marked improvement in the exportation of worsted tissues. The total value of our exports of woollen and worsted manufactures was—

In 1890	£18,926,600
In 1889	19,504,000
In 1888	18,369,000

So that while the general result was not so satisfactory as in 1889, it was more so than in 1888.

The recent return made under the Factories and Workshops Acts shows that in 1889 there were in the United Kingdom 1,793 woollen factories, which employed 3,107,209 spinning spindles, 299,793 doubling spindles, 61,831 power looms, and 147,729 persons of all ages and sexes. The proportions attributable to the three several divisions of the United Kingdom were as under—

	Factories.	Spinning Spindles.	Employés.
England and Wales	1,429	2,477,964	114,209
Scotland	282	566,146	31,077
Ireland	82	64,099	3,443

There were, besides, 753 worsted factories in operation in 1889, employing 2,402,922 spinning and 669,328 doubling spindles, with 67,391 looms, and 148,324 employés.

OTHER TEXTILES.

Besides cotton and woollen textiles, there are those of jute, flax, hemp, and silk. An idea of the absolute and relative importance of each is presented in the following summary from the return already referred to:—

	No. of Factories.	No. of Spindles Spinning.	No. of Looms.	No. of Employés.
Flax	357	1,135,000	48,714	107,583
Hemp	105	41,724	516	10,572
Jute	116	268,165	14,107	44,810
Hair	42	1,987	352	2,583
Silk	623	846,575	11,464	41,277
Lace	408	—	—	16,930
Hosiery	257	—	—	24,838

In the numbers and equipment of most of these there has been a considerable improvement during the last few years, but this is especially the case with jute. The exports of jute yarn have more than doubled since 1880, and in 1890 the exports have exceeded by about 250,000lb. those of the previous year. There has also been a considerable increase in the exports of jute piece goods, and in the exports of linen yarn and piece goods. Silk, again, shows a considerably increased export, although at lower prices for broad stuffs. The average export prices for textiles are appended for a period extending over fifteen years:—

Average Prices of Exported Textiles in Different Years.

Year.	Cotton Yarns. Per lb. d.	Linen Yarns. Per lb. d.	Jute Yarns. Per lb. d.	Linen Thread. Per lb. d.	Woollen Yarns. Per lb. d.
1875	14·66	15·95	3·40	30·77	38·58
1880	13·25	14·25	3·33	31·02	30·33
1884	12·24	13·95	2·79	29·11	23·78

Digitized by Google

The above table is important as showing that the tendency of prices has been in the direction of reduction over the whole period until 1888, and that, although there has been a partial recovery since that year, prices are not now nearly so good as they were ten years ago, when trade was understood to be on a less satisfactory basis. The fact is that lower prices for raw materials, and improvements and economies in production, have enabled manufacturers to make probably as much profit on their generally extended output as they did some years ago, when the nominal prices were considerably higher, but the conditions of production were by no means so satisfactory. At the same time textile manufacturers have had a somewhat anxious time over the whole period, and even in the best of cases the profits are not by any means excessive.

COAL.

In the coal trade the business of the year just closed would have been entirely satisfactory but for the fact that labour troubles have interfered to prevent both employers and employed from enjoying the full measure of the advantages that should result from a large demand and an exceptionally high range of prices. There has been no year since 1873 when the demand for coals was so steady and considerable. Colliery proprietors have been taxed to the utmost to meet the wants of their customers; railway companies have been importuned to provide more rolling stock, in order to secure the adequate transport of the mineral; railway lines have in some cases suffered from a congestion of coal traffic, now rather rare; and consumers have sometimes had a difficulty in procuring all the supplies they wanted. It is expected that the total output for 1890 will exceed 180 millions of tons. Prices have kept up well throughout the year. Household coal has been in very great demand, at prices that recall the coal famine days of 1873, and coke has been in some districts exceptionally scarce, the price at the ovens ranging from 15s. to 17s. 6d. The exports have been 27,729,000 tons, as compared with 26,737,000 tons in 1889. The average export price has been about 13s., as compared with a fraction over 10s. in 1889.

SALT.

The operations of the Salt Syndicate continue to be carried on apparently with a considerable amount of success. The quantity of salt produced in the United Kingdom during the year 1889 was 1,946,496 tons. The quantity produced in 1890 has not been ascertained, but as the exportation amounted to 690,911 tons, being 67,000 tons more than in 1889, it is reasonable to suppose that the output will be found to have been larger. The average price for 1889 given in the "Mineral Statistics" was about 8s., and the average price for 1890, as ascertained from the export returns, was about 18s. per ton. In spite, therefore, of a continued higher range of prices, the production of salt continues to keep up. In most of the chief countries of the world considerable duties are levied on imports of salt, which are, of course, mainly derived from England. France imposes a duty varying from 11¼d. to 1s. 4d. per cwt.; Germany, 6s. 1d. per cwt.; Holland, 10s. 2d. per cwt.; the United States, 4⅓d. to 6¾d. per cwt.; and Spain, 2¾d. per cwt.; while in Italy, Greece, Turkey, Roumania, and Russia (as regards the ports of the Black Sea and the Sea of Azov), the importation of salt is prohibited entirely. Sweden and Belgium, on the other hand, allow salt to be imported free, while Austria only allows it to be imported by special permission, subject to a licence duty of 9s. 6d. per cwt.

CHEMICALS.

One of the most notable events of the year has been the formation of a syndicate in the chemical or alkali trade, which embraces, it is said, all the principal manufacturers in the kingdom, with a view to the limitation of production within a certain figure, and the maintenance of prices. The alkali business is carried on mainly in Lancashire, on the Tyne, and on the Clyde. It is a growing and important industry, importing raw materials to the value of nearly two millions sterling a year, and exporting, in the form of bleaching powder and alkali alone, products of the value of about £1,200,000, not to speak of the quantities consumed in the United Kingdom in allied industries, which must be very large indeed. The necessity for such a combination does not, however, appear to be very apparent. The average export price of alkali in the first six months of the present year was 6s. 2d. per cwt., as compared with a fraction over 5s. per cwt. in the first half of 1888, so that prices had advanced of their own motion before the movement for a syndicate had taken definite form. It has been otherwise with bleaching powder, the average export price of which fell from about 7s. 6d. per cwt. in the first half of 1888 to about 5s. 8d. per cwt. in the first half of 1890. It is to be observed that the price of chemicals has been abnormally low for a number of years, and although some firms, such as Messrs. Brunner, Mond, & Co., have been earning excellent dividends, the majority have had to be content with very lean results.

MINOR INDUSTRIES.

The course followed by most of the minor industries of the United Kingdom in 1890 has been fairly satisfactory, taking one with another. There has been an active business done nearly all along the line, and although in some cases prices have been lower than in the year 1889, labour has been steadily employed, where it was not itself the means of disturbance, and both profits and wages have ruled above the average. The following figures indicate the course of the exports of certain specific industries in each of the last two years—(1 = 1,000):—

		Quantity. 1890.	1889.		Value. 1890.	1889.
Alkali	cwt.	5,853	5,570	...	£1,917	£1,452
Bleaching materials	,,	1,611	1,384	...	467	515
Chemical manures	tons	294	294	...	1,889	1,858
Bags and sacks	doz.	2,436	2,873	...	595	721
Candles	lb.	11,524	11,413	...	240	210
Cement	tons	589	584	...	1,205	1,137
Products of coal		—	—	...	1,268	991
Earthenware		—	—	...	1,899	1,936
Flint glass, &c.	cwt.	1,288	1,341	...	806	828
Plate glass	sq. ft.	2,906	3,524	...	179	222
Paper	cwt.	653	644	...	1,101	1,147
Leather	,,	141	130	...	1,280	1,197
Painters' colours, &c.		—	—	...	1,454	1,437
Oil and floor cloth	sq. yds.	15,236	15,856	...	724	754

The average prices of some of the above manufactures exported from the United Kingdom at different dates compare as under:—

Year.	Alkali. Per Cwt. s.	Bleaching Materials. Per Cwt. s.	Cement. Per Cwt. s.	Flint Glass. Per Cwt. s.	Leather (Tanned). Per Cwt. £	Salt. Per Ton. s.
1875	9·16	8·79	2·61	60·09	8·89	14·75
1880	6·96	6·04	2·50	44·34	7·84	11·49
1884	6·37	8·21	2·25	46·94	9·45	12·91
1888	5·17	7·68	1·90	44·02	8·76	10·81
1889	5·22	7·39	1·95	45·40	9·18	16·15
1890	6·72	5·80	2·05	46·15	9·08	17·85

The same general improvement in realised values that is shown in the above returns would be found all through the piece, with but few exceptions. The general result is reflected in the extraordinarily large increase of the value of our exports for 1890 as compared with the considerable decrease in the value of our imports. There have, of course, been fluctuations of prices during each of the years in the series dealt with which are not reflected in the above averages, but, in general, the export prices, while of little use as a guide to the immediate movements of prices, are of considerable value as showing what has been the average result of the year's business in a particular branch of commerce.

SHIPBUILDING.

The course of the shipbuilding industry has been pretty evenly maintained over the year. The following figures, compiled from Lloyd's returns, show the number of vessels, and their tonnage, that were under construction at different dates during the year:—

	Number of Vessels.	Tonnage.
31st March	543	863,678
30th June	464	739,914
30th September	406	652,248

These figures clearly prove that there has been a substantial falling off in the number of vessels being built at our shipbuilding centres as the year proceeded, and the difference is more accentuated when the figures are compared with those for the corresponding dates for 1889. At the 30th of September, 1889, there were 230,000 tons more under construction than at the corresponding date of 1890. During the third quarter of the year, however, there were 242,000 tons preparing for construction, as against 99,000 tons at the close of the previous quarter, so that, taking the vessels actually under construction and those being prepared, there was a total of 894,000 tons at the end of the September quarter, as against a total of 838,000 tons at the end of the June quarter, indicating that towards the close of the year additional contracts were being placed.

The tendency to build vessels of larger tonnage continues to be a marked characteristic of the trade. According to the Board of Trade returns, the total number of steam vessels built in the United Kingdom in 1887 was 322, having a total of 225,000 tons, which represents an average of only 699 tons per vessel. In 1889 the total number of steamships constructed was 582, having a total of 554,000 tons, so that the average was 952 tons per vessel, or 36 per cent. more. At the 30th September last the total number of steel steamships under construction was 270, and the gross tonnage was 555,000, so that the average was not less than 2,055, as compared with an average of 1,999 tons in the ships under construction at the 30th September, 1889. It must be borne in mind that the Board of Trade figures are given in net, and Lloyd's returns in gross tons, but, even so, the greater size of the more recent vessels comes out very strongly.

Another characteristic of the shipbuilding work of the year has been the continued displacement of iron by steel. At the end of September of 1889 and 1890, respectively, the tonnage being built in steel was as under:—

	1889. Gross Tonnage.		1890. Gross Tonnage.
Steamships	759,532	...	555,220
Sailing ships	73,417	...	74,825
Totals	832,949	...	630,045

While the total tonnage being built in iron at the same two dates was as under:—

	1889. Gross Tonnage.		1890. Gross Tonnage.
Steamships	36,951	...	14,696
Sailing ships	9,995	...	2,750
Totals	46,946	...	17,446

At the latter date, therefore, only a little over 2 per cent. of the total tonnage of iron and steel ships being built in the United Kingdom was of the former material.

The greatest falling off in the shipbuilding work being done at the 30th September, 1890, was on the Clyde, and the next largest decline was on the Mersey. The details for the principal ports are appended:—

Gross Tonnage under Construction at

	30th September, 1890.		30th September, 1889.
The Clyde	165,286	...	229,959
The Tyne	122,158	...	140,434
The Wear	90,609	...	135,799
The Tees	108,435	...	104,792
The Mersey	16,126	...	9,465
Belfast and Londonderry	61,601	...	78,853

Of the total tonnage of shipbuilding under construction at the 30th September last, 427,000 tons were being built for British owners, being 65 per cent. of the whole. Among our foreign customers for tonnage the most important were, at the same date—

Germany,	with	45,110 tons.
British Colonies,	,,	27,150 ,,
Norway,	,,	26,440 ,,
France,	,,	14,495 ,,

SHIPPING.

There has been in the shipping, as in the coal, iron, and other industries, a great amount of difficulty and disorganisation caused during the year by labour troubles. At Cardiff, Glasgow, Newcastle, and other provincial ports, as well as at London, there has been an almost continuous struggle between the shipping firms and the dock hands, which has resulted in the establishment of a federation of shippers and shipbuilders, pledged to stand by each other in resisting what are deemed to be the unreasonable demands of dock workmen. The shipping interest is by no means so prosperous as it was a year ago. Freights are lower nearly all round, and in some cases a good deal of tonnage is laid up. At the same time, the business done in 1890 does not compare unfavourably with the past.

The total entrances and clearances in the foreign trade during the first eleven months of 1890 were as under, compared with each of the two previous years (1 = 1,000 tons):—

	Entrances.		Clearances.		Total.
1890	26,549	...	31,355	...	57,904
1889	28,131	...	30,463	...	58,594
1888	24,763	...	29,055	...	53,818

The tonnage of shipping entered and cleared in 1890 was somewhat less than in the previous year, but considerably more than in 1888. The most important foreign customer of the United Kingdom in 1890 appears to have been the United States, whence 5,076,000 tons entered in the first eleven months, as compared with 4,710,000 tons in 1889 and 3,982,000 tons in 1888. The clearances of shipping for the United States also appear to have improved, amounting to 3,136,000 tons, as against 2,970,000 and 2,832,000 tons in each of the two previous years. In the case of both our foreign and our colonial trades, the entrances to our ports have not shown so large a tonnage as the clearances from our ports, although the United States are in this respect exceptional, as already shown.

In the coasting trade the entrances and clearances compare as under (1 = 1,000 tons):—

	Entrances.		Clearances.		Total.
1890	26,385	...	25,276	...	51,661
1889	26,482	...	25,355	...	51,837
1888	26,672	...	25,338	...	52,010

THE FRENCH EXHIBITION AT MOSCOW, 1891.

(*For description see opposite page.*)

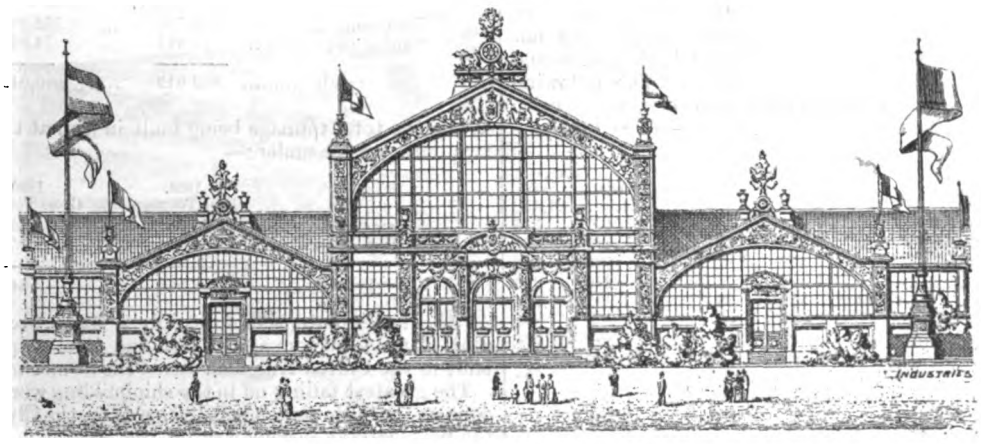

FIG. 1.—VIEW OE FRONT OF BUILDING.

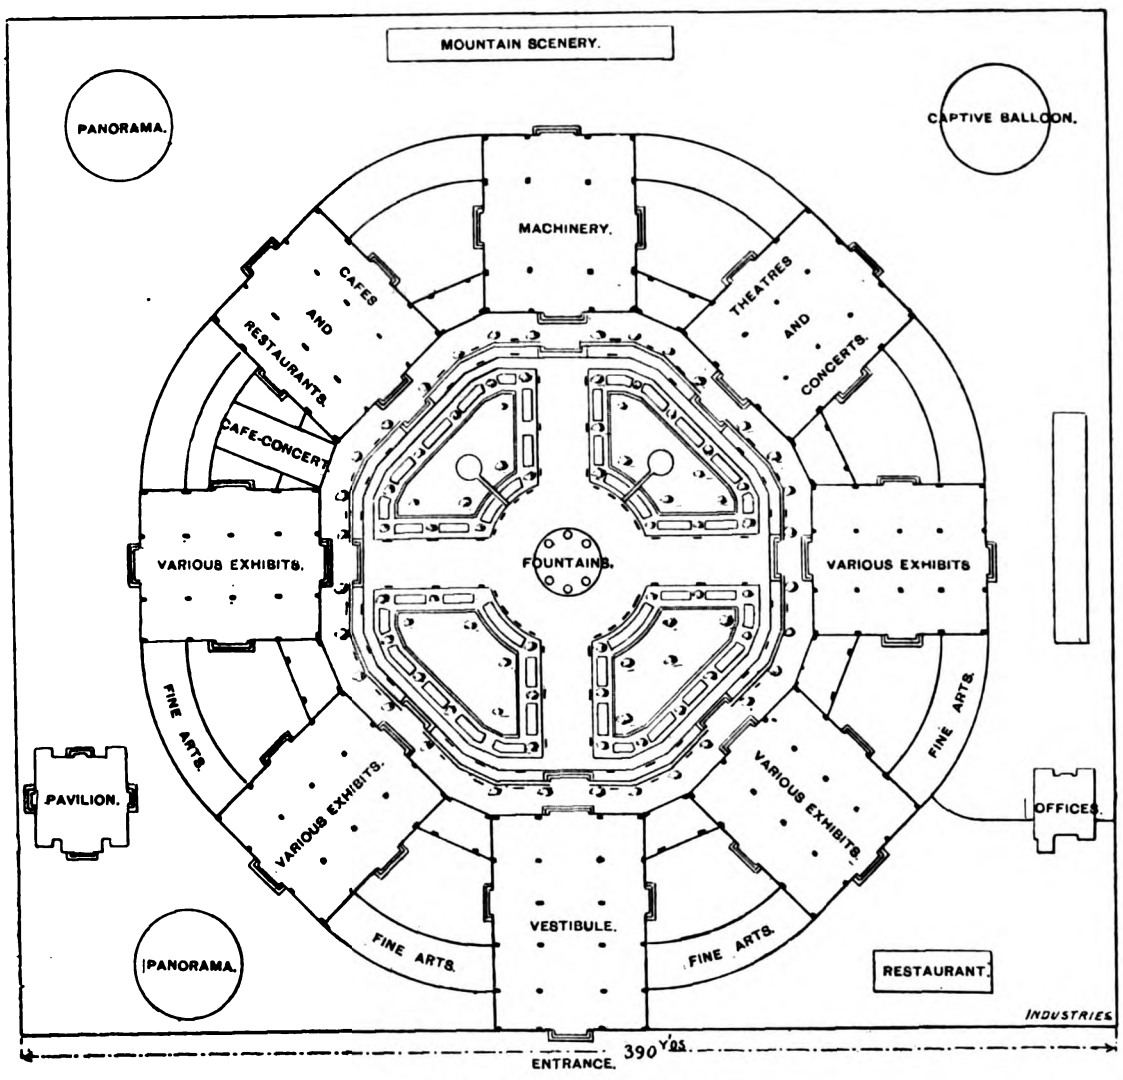

FIG. 2.—PLAN OF BUILDING.

The somewhat monotonous uniformity of the figures which illustrate the course of our coasting trade from year to year is a conspicuous fact, the entrances and clearances over the above period having varied to the extent of less than half a million tons, or less than one-hundredth part of the whole, in any of the years given.

RAILWAY RATES.

Another important event of the year from the point of view of trade and industry has been the close of the inquiry before the Board of Trade Commission relative to the maximum rates and charges, the classification, and the terminal and other arrangements to be made under the Railway and Canal Traffic Act of 1888. The inquiry was one of the longest, if not the longest, in the whole history of railway legislation. The Board of Trade have submitted proposals, alike as to maximum charges and classification, which are decidedly more favourable to the traders than those originally submitted by the railway companies. This, perhaps, was only what might have been expected, since it was an open secret that the railways did not expect to get all that they asked for under either head. But the Board of Trade proposals still leave something to be desired. They propose a terminal of sixpence per ton on coal, whereas the traders hold that a terminal of threepence is not only enough for the services rendered, but is also the sum allowed in certain principal Acts, including the main Act of the London and North-Western Railway. Then there is the question of the accommodation provided at private sidings, for which an indefinite charge may now be made, the question of what constitutes a train-load, and other minor details with reference to which negotiations continue to be carried on between the railway companies, the traders, and the Board of Trade, but on the whole the matter is in a fair way to be now speedily settled, and a Provisional Order will probably be applied for early next session.

TRADE AND FOREIGN TARIFFS.

Perhaps the greatest blow that has been threatened or aimed at British commerce and industry during the year 1890 has been the new American tariff, adopted and brought into operation in October last. This tariff had been under discussion for several months, so that neither merchants nor manufacturers in this country were unprepared for its adoption, and for the results that have both preceded and followed it. On the contrary, the utmost efforts were made by both, in view of the date when the tariff should take effect, to get all the merchandise possible into the United States, in order to discount its provisions, and as a consequence the Customs' warehouses and other centres of business activity in New York and other cities were congested with merchandise for a considerable time previously. The monetary crisis which subsequently occurred in New York has been attributed partly to this circumstance.

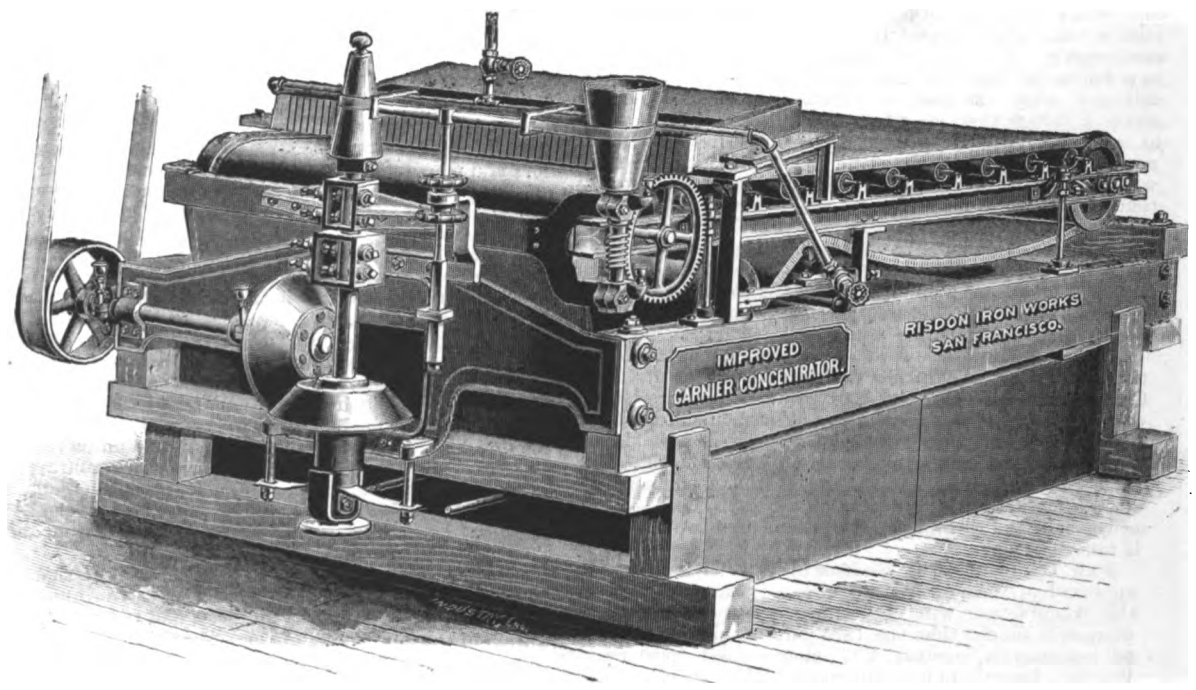
So much importance has been attached to the McKinley tariff, and to its probable effects on British trade, that it is interesting to refer to recent tariff history. Up to 1880 people who introduced tariff discussions were by common consent voted as bores, and it was seldom that the matter came up for public consideration. But the attempt made by the Democratic party to make the tariff a party affair, and to inaugurate a policy founded on lower duties, set the Republicans by the ears, and led to the adoption of a retaliatory policy. The tariff of 1883, the last important measure of the kind, found the average rate of duty on all imported commodities in that year 42·4 per cent. In the following year this was reduced to 41·6 per cent., and was followed in 1885 by an average of 45·8 per cent., and two years later by an average of 47·1 per cent. The Free Trade message delivered by President Cleveland in December, 1887, at the Fiftieth Congress, threw down a challenge which the Republicans were not slow to take up. The result was disastrous to the Democrats. Their opponents secured a substantial majority, and they did so upon the understanding, tacit, if not fully expressed, that the tariff, if interfered with at all, should be altered in the direction of increased duties rather than in that of lower rates. The McKinley Act is the result of this understanding, and it is admitted on all hands to be the most Protectionist tariff that the United States has hitherto produced. It is impossible at this date to say what average rate of duty it will impose on the imports into the country, but it is likely to be higher even than the high average of the years 1867–70, when the exigencies of war expenditure demanded an abnormally high range of duties, founded not so much upon protection to native industry as upon the actual needs of the revenue.

The *raison d'être* of the new tariff is to make provision in the United States for the establishment of industries that have hitherto been only imperfectly developed, or perhaps hardly established at all in that country. Of these undoubtedly the most important is the tinplate industry, which is peculiar in this respect, that it has up to the present time been carried on almost exclusively in South Wales, whence upwards of 300,000 tons of tinplates, valued at over 21 millions of dollars, were imported in 1889. The new tariff substituted a duty of $2\frac{2}{10}$c. a pound on imported tinplates, for the former duty of 1c., so that the amount to be paid in future will be over £10 per ton, or nearly as much as the whole value of the article at the place of production. With this protection it is believed and claimed that the United States will in the near future produce the whole of the tinplates required for their own consumption. The new duty will not come into effect until July, 1891, and it is to continue in force until October, 1897. Nine months are therefore given to the people of the United States to provide themselves with the means of producing their own tinplates, and they will have six years given to them to produce in any one fiscal year as much as one-third of all the tinplates imported for consumption in any year after October, 1890. If this result should not be attained within the period named, then tinplates of lighter weight than 63lb. per 100 square feet shall be admitted free of duty. But there is little reason for doubting that the sharp Yankees will find it possible to comply with this not very onerous condition. Already some Welsh tinplate makers, alarmed at the prospect of having their works stopped at home, are said to be

Digitized by Google

arranging for suitable locations in order to establish works in America, and appear to be thus playing directly into the hands of those who have been seeking to ruin our home trade, on the principle, apparently, of throwing a big sop to Cerberus. The farmers will, meanwhile, have to grin and bear with the prospect of having to pay fully $1\frac{3}{10}$c. per lb. more for the tinplates used in their general tinned-meat industries than they have hitherto paid. The money, in point of fact, will be taken direct from the pockets of the agricultural interest, and transferred to those of those manufacturers who are henceforth to carry on the business of tinplate makers in America.

It is probable that this fact would have raised a considerable revolt on the part of the agriculturists, but for some considerations that have been thrown to them in other directions. Hitherto there has been a considerable importation of both raw and manufactured wool into the United States. In 1889 the value of such imports amounted to about 18 millions of dollars for raw, and to $52\frac{1}{3}$ millions for manufactured wool, in spite of a duty already deemed to be abnormally heavy by importers. Under the new tariff, however, the duty on wool and woollen goods has been generally increased, and this appears to have gratified the farming interest, who look forward to obtaining higher prices for their fleeces. So far, indeed, has this gone, that in Texas, which has heretofore been a distinctly pronounced Free Trade State (and has been represented by Mr. Mills, whose attempts to pass low tariff measures are well known), there has been an almost wholesale conversion to Protection in localities where wool is largely grown. It will, of course, be obvious that this will not affect the farmers of Minnesota and other important wheat-growing States. But there are two things to be said for these—the first, that every farmer in the United States looks forward to seeing his property opened up by the railroad, and industries thereupon established whereby he can not only sell his land at a profit, but his produce at an enhanced price; the next, that the farmers are very largely Republicans, and support the tariff because it is anti-Democratic. The duty on linen and linen goods has been increased, and this will be likely to give an impetus to the linen industry of the United States. In such a case we may probably find that the flax fibre produced by the farmers of the United States will come into requisition for the production of linen goods, instead of being a merely waste product, as at present. This would be a real gain to the flax-growing farmer, who can now utilise only the flax seed in the manufacture of oil-cake, and whose flax crop would thus become of much greater value. The agricultural interests, apart from wool and flax, are not likely to be affected directly by the new Act, and it need not be added that there is no likelihood of the ordinary agricultural produce of the country—cereals, potatoes, and so on—being influenced for the better.



No other tariff matter has claimed much attention during the past year, unless it be the proposed new French tariff. This tariff, as ultimately adopted, will come into force on the expiry of the existing Treaties of Commerce, which is not very far ahead. So far as they have proceeded, the changes proposed in the present tariff do not appear to be favourable to British trade. The matter is, however, being well looked after. The Tariffs and Treaties Committee of the Board of Trade have directed the attention of the various Chambers of Commerce and other commercial bodies to the whole question, and evidence will shortly be taken by that committee as to the effect of the proposed duties on different industries.

RAILWAY TRAFFIC IN 1890.

The railway traffic returns for 1890 tell a very satisfactory tale. It appears that the total traffic receipts of the principal railways showed an increase in 1890 over the eleven months of the previous year of £2,595,000, and an increase over the corresponding period of 1888 to the extent of £6,329,000. This increase has been as marked during the later as during the earlier period of the past year, and it has been equally apparent in goods and in passenger traffic receipts. As regards the former, the total increase for 1890 over 1889 was £1,276,000, and over 1888 it amounted to £3,263,000. Now, the average receipts from goods and mineral traffic per ton carried in 1889 was 2s. 6d., and if this figure is divided into the excess receipts from the same description of traffic in 1890 it would follow that the tonnage carried by the railways in the latter year was about 25 million tons more than in 1888. This is a very problematical figure, however, inasmuch as the railways may have either raised or reduced their rates during 1890, and the result would be affected accordingly. The cost of working the railways of the United Kingdom in 1890 has been considerably more than in the previous year, or in any of the years going back to 1880, owing to the higher cost of labour and materials. Locomotive coal has cost from 2s. to 3s. per ton more, and so with rails, chairs, locomotives, and waggons. It does not, therefore, follow that the net profits of the companies have been higher because there has been so considerable an increase of gross profits. Indeed, it is believed in well-informed quarters that the net results will not be appreciably better than they have been on the average of the last five years.

THE "GARNIER" ORE CONCENTRATOR.

CONSTRUCTED BY THE RISDON IRON WORKS, SAN FRANCISCO, U.S.A.

GENERAL VIEW.

THE "GARNIER" ORE CONCENTRATOR.

THE above engraving represents an improved ore concentrator made at the Risdon Iron Works, San Francisco, U.S.A. These machines have undergone considerable modification during several years, retaining, however, in nearly all cases, the element of an endless apron or band, with some kind of movement to produce agitation of the sand or pulp as it passes from the feed end to the rear one. There are in some machines an "end shake," in some a "side shake," and also, in other cases, a shock or blow.

The present machine differs from all these. The table has a peculiar movement; the vertical shaft seen in front is connected to the apron, or table, by an eccentric bearing at the top, which gives a rotary movement to the apron and its frame at that point. The table is supported at the rear end, partially on the pivot studs seen at the side, and also by a fore and aft sliding bearing in the centre behind, which, permitting a forward and backward movement equal to the throw of the eccentric in front, but no movement sidewise at the rear end, so the sand on the table is first subjected to a kind of mixed circular movement, which is gradually changed to a reciprocating one, as the material moves back from the feeding end. The material is fed on from the hopper boxes seen on top, and the "concentrates" caught below in the usual manner.

The machine is started and stopped without shock by means of the bevel friction wheels seen in front, the horizontal shaft running continuously. The rotary movement of the table is derived from the vertical shaft in front by means of the cone pulleys and a band, as shown. This band is adjusted up or down, while the machine is in motion, so as to regulate at pleasure the movement of the apron over the rollers on which it is supported. The double shipper is adjusted and held by the two small hand wheels seen on the screw stem in front, and every working part of the machine is in plain view and accessible.

On the grounds of simplicity and absence of detail, this concentrator seems to have a good many points in its favour, and supposing its functions, due to the peculiar movement before explained, to have the advantages claimed, the machine will, no doubt, meet with success, especially as the process of fine concentration is increasing in favour, and also in adaptation to the requirements of present gold mining industry in California.

THE FRENCH EXHIBITION AT MOSCOW, 1891.

AN Exhibition is to be held this year at Moscow which will be open for a period of six months—from May to October. This Exhibition will be exclusively devoted to the productions of the French nation, a concession having been obtained by a committee of French merchants and manufacturers from the Czar for that purpose.

The Exhibition will be divided into the following nine sections, as follow:—

1. Fine Arts.
2. Education. Liberal Arts.
3. Furniture and Accessories.
4. Textiles.
5. Raw Products.
6. Machinery. Electricity.
7. Food Stuffs.
8. Agriculture. Vine Culture.
9. Horticulture.

The Exhibition will be held in the building which was erected for the Russian Exhibition of 1882. We give in Figs. 1 and 2 on the previous page an elevation and plan of the building. The building is of an octagonal form, and consists of eight large pavilions connected together by galleries. Each of the eight pavilions has a length of $60\frac{1}{3}$ metres, and a breadth of $51\frac{1}{2}$ metres. The total amount of space under cover is about 35,000 square metres. The space in the centre is laid out as a garden, in which fairy fountains are being erected, such as were used at the late Paris, Manchester, and Glasgow Exhibitions.

The Exhibition will be lighted throughout with the electric light, which is in the hands of one of the principal Paris companies.

Every facility is being given to induce the French manufacturers, &c., to send exhibits, and already a large number of applications have been made for space. The French, therefore, are not likely to let slip such a good opportunity of making the productions of France better known to the Russian people. We are indebted to the *Société des Ingénieurs Civils*, of Paris, for our illustrations.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 30th December, 1890.

Iron.—Business is this week practically at a standstill in the iron markets; but enough has been done to show a distinctly marked downward tendency in prices. The year ends with a weak market for bars at 132s., and for joists at 136s. a ton. The prospect for the new year is, however, encouraging. The fact that consumers are willing to pay 4s. a ton more than the rates now current for iron to be delivered after the end of February is evidence of a state of things that must bring about a recovery as soon as we have fairly entered on the year 1891. The latest news from the provinces is of the same character—present weakness with a prospect of speedy recovery. The situation is at its worst in the Nord. The Customs' returns for the first eleven months of the current year show the following changes relatively to the corresponding period of 1889:—Imports: Pig iron, 129,142 (110,692) tons; finished iron, 28,860 (25,453) tons; steel, 7,918 (8,752) tons. Exports: Pig iron, 158,827 (91,690) tons; finished iron, 63,530 (5,912) tons; steel, 38,912 (29,759) tons.

Metals.—The downward movement in metals continues. Copper has further declined several points, best Chili bars being offered at £58. Buyers hesitate, however, to deal at that price. The recent financial crisis in London seems to have crippled the group of speculators who have for so long a time controlled the market. The same cause probably has led to a further decline in the spelter market. Tin has also given way. Lead has receded a little in sympathy, but the market for this metal is fairly strong.

New Carbine.—The Minister of War having formally approved of the new pattern of cavalry carbine proposed, the manufacture will be commenced forthwith. This weapon is shorter than the 1874 pattern, hitherto in use—96 centimetres, against 1·17 metres—and considerably lighter. Its calibre is 8 millimetres. The effective range is said to be 2,000 metres. It is a repeater, the magazine containing three cartridges. The small arms factory at St. Etienne is under contract to supply 30,000 carbines in the first three quarters of 1891.

BERLIN, 29th December, 1890.

Iron.—Business in the iron market is, on account of the holidays, almost at a standstill. Nevertheless it is possible to perceive a further improvement in the situation. The tone of affairs generally is stronger. In Upper Silesia the stocks of pig in the hands of the blast furnace owners, never very large, have been perceptibly reduced in the course of the last three weeks. The manufacturers of finished iron and steel have orders enough in hand to enable them to begin the new year free from great anxiety, to say the least. Favourable reports, too, have been received from the Rhenish-Westphalian districts, where pig iron has become very firm in price, with a distinctly upward tendency in some sorts. The total production of pig iron in Germany, including Luxemburg, in the month of November amounted to 361,384 tons, against 373,090 tons in the previous month and 389,116 tons in November of last year. This brings up the total for the first eleven months of the current year to 4,200,465 tons, against 3,995,981 tons in the corresponding period of 1889.

The Silesian Nickel Deposits.—The newly discovered deposits of nickel and chrome ores near Frankenstein, in Silesia, are turning out to be very rich. Herr Krupp has ordered the immediate delivery of 100 tons of nickel ore, 20 tons of which have already been despatched from the mine. Herr Krupp has, it is said, offered 1,500,000 marks for these mines. The discovery of these deposits is an important event in the history of the German iron and steel industry.

Smokeless Powder Manufacture.—Hitherto the posts of superintendents and managers of the powder factories at Spandau have been filled by artillery officers. These are now to be replaced by civil engineers and chemists, it having been found necessary to employ men possessing special knowledge and training in the manufacture of the new smokeless powder. The production of this powder involves operations demanding high scientific attainments on the part of those whose duty it is to direct them.

Navigation on the Rhine.—According to the latest edition of the navigation register 6,502 crafts ply on the Rhine, amongst which are 661 steamers. Of the wooden ships 2,637 go under the Dutch, 568 under Prussian, 450 under Belgian, and 828 under other flags; of the iron boats, 566 under Dutch, 511 under Prussian, 104 under Belgian, and 177 under other flags; of the paddle-steamers, 105 under Prussian, 32 under Dutch, 14 under Hessian, and 16 under other flags; of the screw-steamers, 229 under Dutch, 141 under Prussian, 58 under Belgian, and 66 under other flags. Messrs. J. P. Lanz have established a regular goods service between Mannheim and Antwerp.

Firearms.—A Bill has been brought into the Reichstag to render it obligatory on all manufacturers of firearms to submit the barrels and breech mechanism to certain tests about to be imposed. These tests will be similar to those of the London and Birmingham proof-houses. Any manufacturers offering firearms for sale not bearing the proof-house mark are to be made liable to heavy fines and imprisonment. It is surprising that this measure was not taken years ago. A similar law to that now proposed has long been in force in Belgium, France, and England. The large export trade in German guns makes this question of proof one of wide interest. The declared value of sporting guns and parts thereof (chiefly barrels) amounted in 1885 to 1,385,000 marks, in 1886 to 1,076,000 marks, in 1887 to 944,000 marks, in 1888 to 1,174,000 marks, and in 1889 to 2,155,000 marks. In 1882 there were in Germany 1,686 gunmaking firms, only six of which are classed as employing over 200 and less than 1,000 hands. The total number of persons employed in these works in that year was 6,647.

VIENNA, 29th December, 1890.

The Iron Market.—At a recent meeting of owners of mines and manufacturers of iron and machinery, under the presidency of Count Larisch-Moenich, an authoritative report on the mining industry for the past year was presented. After reference had been made to the late Prince Salin, who was formerly president of the society, the following report was submitted to the meeting:—There has been a steady business during the past year, both in the coal mining industry and in the production of coke, the consumption being regular. The traffic arrangements have been good throughout the year, and the results of last year's trade may be regarded with satisfaction. The condition of the pig iron industry and of the production of medium and refined qualities was very favourable during the first half of the year, and prices showed an increase as compared with those of the previous year. During the summer the speculation of foreign markets caused an unnatural rise in prices, which had its effect on the home market. In consequence of increased production, and a decrease in the demand, producers were obliged to make concessions, and prices are now generally lower than they were in the first half of the year. There is now no excess of production in the iron industry, and the present condition of the market is sound. There is a good prospect for next year, if the agreement with the German Empire should not have the effect of allowing foreign goods to enter our market through a reduction of the customs duties.

Copper, Zinc, and Tin.—The tin, zinc, copper, and mercury industries have done a steady business during the past year. There was no important fluctuation in prices, and the decrease which was caused by a fall in the exchange was compensated by a rise of prices in foreign markets. No change in the favourable condition of business is to be feared, since important contracts have already been concluded at the existing high prices, and larger supplies are wanting. Under these circumstances our mining and iron industries expect that their interests will not suffer by reason of the negotiations now being carried on with other districts. The St. Egydier iron works made similar announcements on the occasion of their general meeting, which would indicate a higher dividend than that of the previous year. Owing to the holidays, business is now entirely suspended.

Electrical Railway from Vienna to Budapest.—A movement is being started in Vienna and Budapest to obtain a concession for the carrying out of preliminary works for an electrical railway between Vienna and Budapest. A speed of 100 kilometres per hour is to be attained, and the distance is to be accomplished in about three hours. In the technical departments of the Ministry of Trade the project is looked at very sceptically, and is considered premature in view of the present condition of transmission of power from a distance. No decision has yet been given in the matter.

BRUSSELS, 30th December, 1890.

Iron.—The general aspect and tone of the iron markets is unsatisfactory. The produce of the blast furnaces is disposed of with difficulty, and prices are weak and drooping. The Cockerill Company have blown out two of their seven furnaces. Production everywhere is being reduced, yet stocks continue to accumulate. Matters are but little better in the rolling mills. The home demand has dwindled away to nearly nothing, and export orders are secured only by making such concession in prices as leave a loss on the transaction. The Customs' returns for the first ten months of the year show a falling off relatively to the corresponding period of 1889. Thus the year 1889 ends in depressing circumstances, unrelieved by any promise of better things in the near future. The difficulties of the situation, already very great, seem likely to be yet further increased by dearer fuel, the attitude of the colliers being such as to destroy all confidence in the stability of the coal markets.

Glass.—Business in the glass market is very slack, largely on account of the holiday season, but partly also by reason of the weak tendency of prices, which leads consumers to defer their purchases. The time is not far distant when the prices of German plate glass will have to be reduced, and a change of that sort must operate unfavourably upon Belgian trade, which already suffers keenly from German competition. The export trade to England continues moderately active, but is considerably below that of last year at the same season. The recent rise in soda sulphate has made the situation critical.

New Small Arms Factory.—The erection of the small arms factory at Liège for the manufacture of the new rifle for the Belgian army proceeds apace. The buildings will cover some 8 hectares. One of these will enclose 10,000 square metres, the roof of which will be supported on 400 cast-iron columns. When completed this factory will be one of the largest and most perfectly equipped in the world. The newest designs of machinery will be employed. Some of the machines have been purchased in Germany; the rest, for the most part, in the United States. The works, which will cost about 4,000,000fr., will be capable of turning out 250 finished rifles daily.

DÜSSELDORF, 30th December, 1890.

Iron.—Though there is but little business doing in this holiday season, it is easy to discern an improving tendency in the state of the iron markets. Prices have become very firm. At the last meeting of the Rhenish-Westphalian Pig Iron Makers' Association, held on the 22nd inst., it was decided to make no change in the minimum. A circular issued by the Joint Manufacturers' Union directs attention to the underselling which has been going on among merchants, and informs customers that no reduction will be made by the manufacturers, and that therefore this "bearing" speculation must fail. The prospects of the pig iron market have greatly improved of late. According to present indications, a moderately brisk demand, likely to grow as spring approaches, may be expected in the second half of January. The willingness with which the recent rise in the price of bars is paid by consumers is a hopeful sign. The situation of the finished iron and steel markets is, on the whole, strong and full of promise for next year's trade. The export business is still very slack; but though slowly, it is steadily and constantly reviving.

Coal.—The demand for coal is unprecedented in this district, and the mines are being worked to the utmost of their capacity. The output now reaches 120,000 tons a day, the railways being taxed to the utmost of their powers to keep the pit banks clear. This extraordinary demand, coupled with the formation of syndicates to control and regulate the markets for all sorts of coal and coke, renders it certain that no reduction of prices will take place this winter, and probable that the present level of prices will be maintained for many months to come.

Founders' Prices.—The Hesse-Nassau group of the Association of German Ironfounders held a meeting at Frankfort the other day, at which the influences now operating to increase the cost of production were discussed. The general conclusion arrived at was that, in view of the present state of the labour market and the certainty of the prices of coal and coke being maintained for a long time to come, it was undesirable to reduce the prices of castings. It was further agreed to restrict production to the current needs of consumers.

LILLE, 30th December, 1890.

Iron.—There is no sign of speedy improvement in the iron market of this district. Bars and joists are pressed for sale, not only by merchants, but by manufacturers, so that the price is weak at 112s. a ton. Very little business is being done even at this price. The calm is in large part due to the holidays and the stocktaking season; but, apart from this, the situation is weak. Great changes must take place before there can be anything like a return of activity. Thus the year 1890 ends in unfavourable circumstances in so far as the iron industry of this locality is concerned, and the prospect for 1891 is depressing.

Textile Manufactures.—Very little business has been done in linen goods in the course of the last week. The holiday season is now in full swing, and no resumption of business is to be looked for till near the middle of January. The tone of the market is good, and there are indications of a brisk spring trade. Prices remain unaltered. The year ends favourably for the Roubaix woollen goods trade. Manufacturers are busy on summer orders. It is yet too early to predict what patterns will "take," for the travellers are but just starting on their rounds with the new designs, but it is likely that the fashion will run on very light goods.

Flax and Yarns.—The situation has changed but little during the past week in so far as flax is concerned. The holidays have brought business almost to a standstill, but enough has been done to show a weak tendency in prices. There has been a moderately brisk demand for fine linen yarns, and prices are higher than they were at the close of last week. This is the only direction in which there has been anything like activity. The calm may be expected to last till the end of the first week in the new year.

AMSTERDAM, 29th December, 1890.

Holland and the Crisis in the River Plate.—The economical crisis in the Argentine Republic has reacted most seriously upon the trade with Holland, which was, comparatively speaking, of recent growth. The Consul-General of the Netherlands at Buenos Ayres has sent repeated warnings against emigration to the River Plate under the present circumstances, and his latest communication to his Government upon this subject is more emphatic than ever. He writes—and his letter is printed in the *Official Gazette*—that the crisis is not by any means past, but rather goes on deepening, and seriously presses upon all trade, but particularly upon the artisan class. Agriculture, he maintains, is in a sorry plight, and peasant colonies are far from flourishing. Under such depressing

Digitized by Google

circumstances the Dutch Consul-General once more deprecates emigration, especially of the artisan class, even where the passage money should be advanced. In connection with these repeated warnings, it should be noted that the Netherland-American Steamship Company has decided to discontinue its South American business for the present. Until further notice no steamers of this line will leave Rotterdam for the River Plate. The resolution was come to all the sooner by the directors because the South American branch of the business had not yielded brilliant results from the beginning, and freight was latterly at a very low ebb. For Rotterdam the stoppage of these steamers means a great loss. Latterly the imports of Brazil coffee by them had developed immensely, no less than 165,629 bags being landed there this year to the end of November.

THE WEATHER AND NAVIGATION.—As previously reported, the severe frost has seriously impeded navigation upon our rivers and canals. Upon the North Sea Canal, however, communication has been restored by the united efforts of two English steam vessels, the "European" and the "Seahorse," efforts stimulated by the offer of a premium of 5,000 guilders for the breaking up of the thick ice by a combination of interested merchants. Thirteen vessels immediately availed themselves of the opportunity to reach Amsterdam. Curious to say, the Government, to which the canal belongs, does not consider it a duty to keep the the waterway open under all circumstances. In 1881, under similar circumstances, the above-named "European" earned a gold medal for "forcing" the ice in the canal.

NEW LINE OF STEAMERS TO JAVA.—The Ocean Steamship Company (Holt Line), of Liverpool, will on the 15th February next inaugurate a new fortnightly service of steamers from Amsterdam to Singapore and Java. The first boat from Java will leave early in January. The same steamers had already, at irregular intervals, transported Sumatra tobacco to Amsterdam, where arrangements are completed for loading and discharging.

STOCKHOLM, 27TH DECEMBER, 1890.

NEW RAILWAY MATERIAL.—The Board of the Swedish State Railways have applied for a sum of 1,500,000kr., to be applied to the purchase of new rolling stock. The sum of 580,000kr. will be applied to the purchase of ten new locomotives, and the balance to the purchase of 230 covered carriages, of which thirty shall be passenger carriages. The Board have already ordered rolling stock to the extent of the funds available up to the end of 1891. When these orders are completed, the State railways will have 329 locomotives. Of these, 30 are, however, of such an old type that they are only used in cases of emergency. The express train locomotives have to do about 45,000 kilometres, and the goods train locomotives an average of 28,000 kilometres per annum. This heavy working entails considerably increased repairing expenses and too much wear and tear of the locomotives. The insufficiency in the number of locomotives makes it impossible to repair them soon enough, and the Board of the State Railways contemplate a further increase in the number of locomotives. The same remark applies to the carriages, of which about 1,000 goods carriages and 200 passenger carriages require repairs.

WOOD PULP.—The whole of 1891's production of that kind of wood pulp which is being treated with soda (soda pulp) has been bought by a London firm. It is consequently expected that this class of wood pulp will experience an advance, whilst all other kinds are dull.

ICE-BREAKING STEAMER FOR RUSSIA.—The new ice-breaking steamer "Ledohold," built at the Lindholmen shipyard, had a very satisfactory trial trip on the 15th inst. During the trial trip the "Ledohold" made 11¼ knots, against 10 knots as per contract. The engines are of the triple-expansion type, and the propeller is "Stone's patent." The entire material and the whole machinery are Swedish. The steamer's destination is Nicolajev, on the Black Sea.

LARGE RAILWAY BRIDGE.—A large bridge from the Bergsund Engineering Company has just been delivered and fixed over the Lögde River. The bridge has a length of 110 metres in three spans of 33·75 metres, 40·5 metres, and 33·75 metres respectively. It rests upon two high steel piers, and the road of the bridge lies about 28 metres above the level of the river. The cold during the fixing has reached as much as -32° C. The material is Domnarfort steel.

CHRISTIANIA, 27TH DECEMBER, 1890.

MORE NEW VESSELS.—A steamer, intended for fishing purposes, has recently been ordered at the Frederikstad Engineering Company by Captain T. Beck. The dimensions are as follow:—Length, 127ft.; breadth, 19ft.; and depth in hold, 13ft. The engine is to be triple-expansion, of 350 i.h.p.; boiler, 11½ft. in diameter and 10ft. long. It is to have a considerable speed, and to be used at the Lofoten fishery. At Christiansand a new syndicate has been formed for the building of a 2,500 ton steel vessel. What is probably the largest wooden vessel ever built in Norway was launched a few weeks ago at Hölen. She has been named Excelsior," and is built to the order of Consul Oppen. The tonnage is about 1,450 tons; length, 203ft.; breadth, 39ft.; and she is built exclusively of first-class materials. The bottom masts are of iron. The "Excelsior" will be fitted with steam winch and all other modern appliances, and is intended for the Australian trade.—The various Norwegian shipyards continue to be very busy.

FISH MEAL MANUFACTORY.—A fish meal manufactory has been started at Vordö by Professor Wange, who has himself superintended the erection of the works at this remote place.

VOLLÖ PAPER MANUFACTORY.—A large wall paper manufactory has been rebuilt at Vollö in lieu of the one burnt down last year. The production is expected to reach 3,000 rolls of paper, each 24ft. long, per diem. The works turn out wall paper of the most varied kinds. The principal market is Norway, Sweden, Finland, and Denmark.

SALVAGE STEAMER.—The want of an efficient salvage steamer on the Norwegian coast has been felt for a considerable time. The steamer built by Mr. Binz will be about the same size as the well-known Switzer Company's steamers, and is two or three times as large as any other Norwegian salvage steamer. Its dimensions are—length, 122ft.; breadth, 23ft.; depth, 13ft.—and it has a capacity of 198 registered tons. It has been specially constructed with a view to seaworthiness, and was constructed of the best timber at a shipyard close to Bergen. It is built to the highest class Veritas. The vessel will be fitted out so as to be used both as a life-saving and a salvage steamer.

NEW TEXTILE MANUFACTORY.—A new textile manufactory has been erected at Kongsberg, under the style of the "Konsberg Tricatoze Fabrik," and there seems altogether to be a good feeling in that locality for industrial enterprise.

COPENHAGEN, 27TH DECEMBER, 1890.

THE COPENHAGEN BREWERIES.—For about a year negotiations have been pending with the view of bringing about an amalgamation of all the Copenhagen breweries, with exception of the Tuborg, the Gamle Carlsberg, and the Ny Carlsberg breweries. The prospects of such an arrangement have fluctuated considerably, and more than once the scheme has been looked upon as virtually abandoned. The efforts of Mr. Tietgen have now been crowned with ultimate success. About a dozen breweries in Copenhagen and its immediate neighbourhood will now be amalgamated into one large brewery company, with a capital of about 12,000,000 kr. The plan was a difficult one to realise, for the breweries in question were paying widely different dividends on their capitals. One or two, in fact, showed very little profit. In addition to this cause, a natural opposition to the plan was shown by one or two of the breweries outside the arrangement, one of them having made a very good offer for one of the breweries in the ring. Their names are:—Kougens, Beyghus, Marstrands, Aldersro, Robeshove, Rahbeck's Allee, Svanholm, Toedes, and Frederiksberg.

MADRID, 29TH DECEMBER, 1890.

THE HUELVA FUMES.—The Royal decree, which prohibited the open-air roasting of pyrites, has at last been repealed. The present decree is only provisional, but a permanent measure will be introduced at the next sitting of the Cortes. It seems certain that the quantity of ore treated by the present method, which is so destructive to the surrounding country, will be lessened. The present decree gives the companies time for the adoption of a less harmful method of treating the ores.

THE NEW SCHOOL OF MINES.—Building operations have been suspended for some months, in consequence of a proposed change in the kind of material to be used, but will now be actively carried on. The building will be a fine one, and suitable for its purpose.

THE "GRAN CENTRAL ESPAÑOL" RAILWAY COMPANY.—Certain lines of railway are to be amalgamated under the above title, which has been given in imitation of the Midland Railway Company in England and the "Grand Central" in France. The lines do not seem well fitted for amalgamation, and the system is defective in consequence of its being connected with only one port, Pasages. The system will not be really connected with Lisbon and the Portuguese lines. In addition to these disadvantages, it does not pass through any coal district, and its only entrance into Madrid is over the Zaragoza line for a distance of at least 150 kilometres. The line from Madrid to Caceres, 429 kilometres in length, is to be amalgamated with the system, together with some other lines in process of construction. The scheme is intended to relieve the Royal Portuguese Railway Company from obligations entered into with the Caceres and Western lines, which entailed an annual loss of £120,000. According to this arrangement the loss will be reduced to a half of this amount, and the Portuguese Company, which is in a sound financial condition, will hand over 70,000 debentures of £20 each and receive the same amount of debentures from the Gran Central, thus exchanging a saleable security for what is at present unsaleable. When all the lines of the new company have been completed, the distance from the French frontier to Madrid and Lisbon will be shortened.

THE ELECTRIC LIGHT AT THE CONGRESS BUILDING.—It has now been decided that the building of the Congress de Dipitados (House of Commons) is to be lighted electrically. A commission has already been appointed to deal with the matter, which must be promptly carried out if the installation is to be ready before the opening of the Congress next spring.

EXPORT OF IRON ORES FROM BILBAO.—The exports for the past year are the largest on record, even including those for the year 1887, when, owing to low freights and prices, the shipments were in excess of the actual demand.

NEW YORK, 20TH DECEMBER, 1890.

RAILWAY ASSOCIATION.—The conference which was held in New York on the 15th inst. by officials of the Western railways for the purpose of forming a railway association promises to have a beneficial effect on Western business. The principal purposes of the association are to be the establishment and maintenance of public, reasonable, uniform, and stable rates, which shall be fair to the business public and yet leave a margin of net earnings to the railways; to secure to each railway in the association the due proportion of business to which it is naturally entitled; to prevent unnecessary and expensive diversions of traffic; and to introduce new methods in freight and passenger traffic, the aim being to accomplish these results by the introduction of economies in doing business without increasing the rates.

STRIKE IN THE RIBBON TRADE.—About one hundred ribbon weavers in the silk mill of Mr. C. E. Weding and fifty-six in Messrs. Francke & Duggan's mill, Paterson, N.J., struck recently in consequence of a proposed reduction of wages amounting to from 20 to 25 per cent. The reduction applies to wages after the present ones are run out. The manufacturers say they are forced to take this course by the unprecedented dullness in the ribbon business, and that similar action will probably be taken by all the manufacturers. Unless the reduction is accepted by the weavers the owners say that the mills will be closed, as they have been running at a loss for some time. The strike is considered ill advised, for the prospects are not at all good for the silk business.

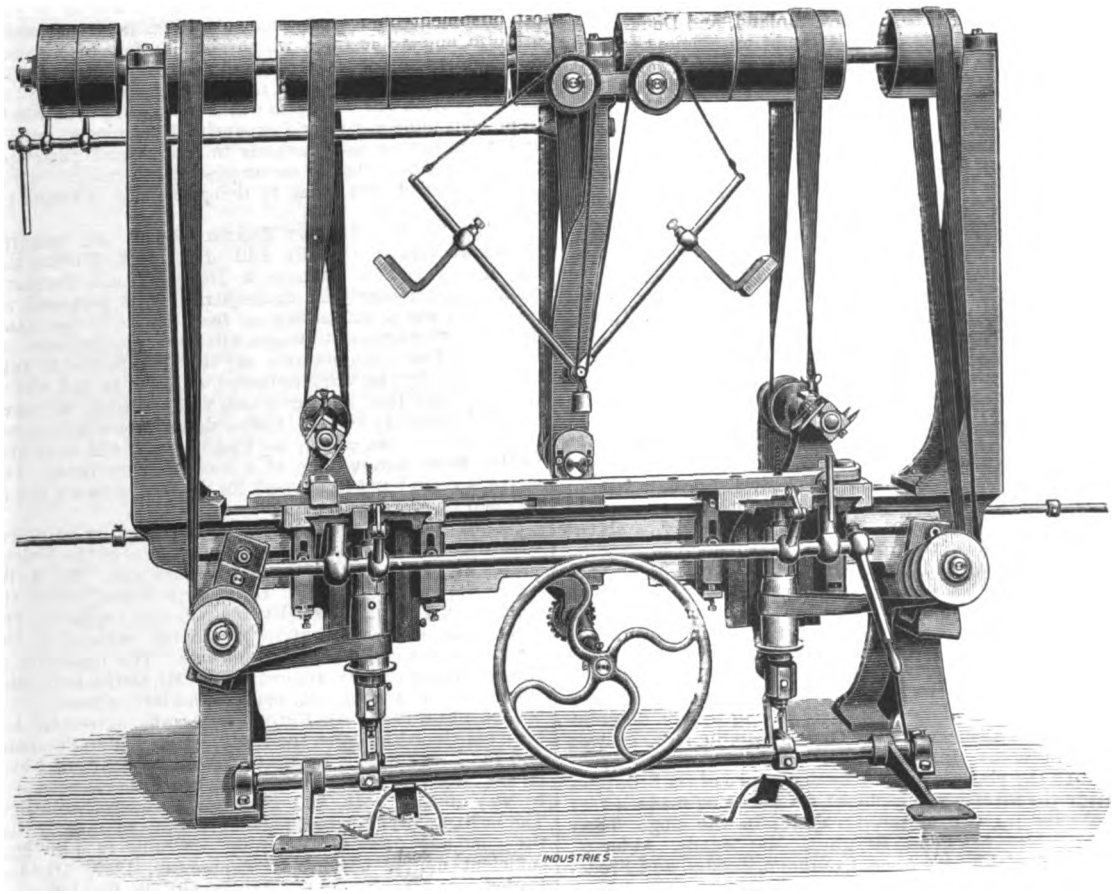
BARBED WIRE.—A largely attended meeting of representatives of the barbed wire manufacturers of the United States was held in Chicago a few days ago. Mr. J. W. Gates, representing the St. Louis Wire Works, called the meeting in a circular issued two weeks ago, requesting the attendance of representatives of all the makers, as the meeting was to be an important one. The intention of the manufacturers, as announced by Mr. Gates, is to raise the prices on barb wire 1c. per lb., and form a trust.

THE POUGHKEEPSIE BRIDGE.—A traffic agreement has been concluded between the Baltimore and Ohio Company and the Poughkeepsie Bridge Company, by means of which all the New England freight, which has hitherto been sent by way of New York, will hereafter go over the bridge. The business over the bridge is increasing so rapidly that the company finds considerable difficulty in providing sufficient motive power. In September, 1889, fifty-two loaded cars passed over the bridge, and in the following month the number was doubled. In May of the present year the business had increased to 800 cars, in October to 1,800, and in November to 2,400. The receipts are now sufficient to pay the fixed charges, as well as the working expenses, and it is expected that the company will soon be earning sufficient to pay the fixed charges and working expenses on the entire system.

PHILADELPHIA, 19TH DECEMBER, 1890.

THE COAL TRADE.—There has been little change in anthracite. Production is pretty heavy, and prices are lower than in the autumn. In consequence of the colder weather local trade has somewhat increased. The condition of trade has not been favourable during the past two years, and an improvement is hoped for. The stocks of coal in the hands of retailers are not very large, and as a number of mines are reducing their output a better trade is expected.

SUSPENSION OF AN IRON FIRM.—The directors of the Bessemer Rolling Mill Company, of Birmingham, Ala., have decided to place their affairs in the hands of a receiver. The company lost $30,000 by the recent failure of the United States Rolling Stock Company, of Chicago, which was the direct cause of the suspension. The company's mill has been in operation two years, and 600 men were employed. The receivers will try to keep the mill running, and it is thought that all the debts of the company will ultimately be paid.



THE GLASS TRADE.—At a meeting of the Western Flint Glass Association on the 10th inst. reports were received which showed that the pressed ware business was in a bad condition. Nine houses, in which pressed glass ware was manufactured, have partly or entirely closed down recently, and several others were likely to do so in the near future. The depression is attributed to the Bill recently passed by Congress, which, to a great extent, stopped the advertisement of firms offering table ware as an inducement to their patrons. Other branches of the trade are prospering, the makers of chimneys and bottles reporting their business to be in first-class condition.

PAPER MILL ASSOCIATION.—A meeting of the Western Wrapping Paper Mill Association was held in Chicago a few days ago. This association controls the entire wrapping paper business in the West. Hereafter the entire product of the mills in the association is to be sold by the agents of the organisation instead of by the salesmen of the individual mills. Arrangements were made for keeping the standing committee of the organisation informed of the operations of every mill.

MACHINE FOR SHAPING AND BORING TELEGRAPH POST ARMS.

CONSTRUCTED BY MESSRS. JOHN PICKLES & SON, ENGINEERS, HEBDEN BRIDGE.

FRONT VIEW OF MACHINE.

MACHINE FOR SHAPING AND BORING TELEGRAPH POST ARMS.

THE above illustration represents an ingenious machine which has been lately made by Messrs. John Pickles & Son, Hebden Bridge, *viâ* Manchester, for preparing telegraph post arms. These arms are usually made from the best selected English oak, and vary in length from 2ft. to 4ft. They are in the first case planed on the four sides by means of a special planing machine made by the above-named firm. They are then sawn to the exact length required by means of a double cross-cut sawing machine made specially for the purpose. The arms are then passed along to the machine we now illustrate. This machine is provided with a fence bar, in which the arms are held fast by a novel screw clamp. By means of the hand lever shown to the right the arm is carried, by the slides, between cutters revolving at a high speed. These cutters complete the end chamfering, and at the same time the central hole is bored by a revolving boring bit. After this the slide carrying the arm is moved up against an adjustable stop, and the operator turns the large hand wheel. This is connected by bevel and other gearing to the cutter headstocks, and causes the latter to move towards each other up to a given point in accordance with the length of chamfer required, which may be from 7in. to 17in. in length. The cutters revolving at a great speed take off the chamfer on both sides of the arm and also at both ends at the same time. The bars shown at the ends of machine have gauge stops fitted for giving the length of traverse required. The headstocks are after this rapidly wound back to their first position and are ready for the next operation. The operator then places his foot on the foot lever, which causes the two heads carrying revolving boring bits to rise and bore the holes at each end required for fixing the insulators. The pads connected with cords and levers on the central standard are intended to prevent the boring bits splintering the wood when coming through the top side.

It will be seen that the machine is quite self-contained, and has the driving shaft placed overhead and supported upon standards fixed to the main bed. The arrangements for dealing with the various lengths of arms have been carefully thought out. At the official test of the machine in the presence of the purchasers the wooden arms were finished at the rate of three per minute. This result reflects credit on the makers of this special machine, and speaks well for its efficiency.

THE BOILER EXPLOSION AT THE HAYBRIDGE IRON WORKS.

ABOUT midnight on the 10th November last a boiler explosion, which fatally scalded one man and injured three others, occurred at Haybridge Iron Works, near Wellington, Salop. An inquest was held on the body of Ralph Owen (the man fatally injured) on the 12th November, at which some preliminary evidence was taken, and it was then decided to adjourn until the 28th November. On that date the inquest was resumed. Mr. Littlewood watched the case on behalf of the Haybridge Company. After a puddler and two of the injured men had been examined, Mr. John Mills, engineer for the southern district of the Scottish Boiler Insurance Company (in which company the boiler was insured) gave evidence to show that "the explosion was caused by sediment mixed with the grease from the engine becoming deposited on the plate, and preventing the free activity of water passing through the plates, which, in consequence, became overheated and crushed in by the ordinary working pressure of the boiler." The jury, after considering the matter, returned a verdict of "Accidental Death," to which they added a rider "that in their opinion the practice of allowing grease to enter the boilers at Haybridge Iron Works is dangerous, and should be discontinued, and that the coroner be requested to convey this opinion to the Haybridge Iron Company."

On the 18th ult. the Commissioners of the Board of Trade, Mr. Howard Smith and Mr. W. C. Lang, held a formal investigation as to the cause of this explosion, there being present Mr. Clement Groom, of the Haybridge Iron Company; Mr. Littlewood, representing the company; Mr. J. F. L. Crosland, chief engineer of the Boiler Insurance and Steam Power Company, Limited 67, King Street, Manchester; Mr. John Mills, engineer of the Scottish Boiler Insurance Company, Limited; and Mr. James Aston, inspector for the same company. After hearing evidence from all the persons who had been connected with the examination and working of the boiler, the Commissioners came to the conclusion that, "so far from being an accident, it was almost a certainty that the boiler could not have worked any great length of time without exploding." The whole of the facts of the case are contained in the very able summing up of the President of the Court, Mr. Howard Smith. We quote below his concluding remarks, as they will be of special interest to steam users. Speaking for his fellow Commissioner, as well as for himself, Mr. Smith said:—

"We are asked some questions as to the duties of insurance companies generally. We are further asked to say whether a company is justified in issuing a policy without examination. The answer to that I have already given. But if by 'justified' is meant whether there is any legal obligation to examine boilers before being insured, then I answer emphatically no. But we do think, in the interests of minimising these accidents and preserving human life, it would be better if insurance societies would examine before they insured boilers. As a matter of fact, I believe the Boiler Insurance and Steam Power Company do, unless it is satisfied of the newness of the boiler. I am bound to say that the companies try to get an examination as soon after insuring as they can.

"As far as Mr. Mills' inspector's report is concerned, his company seems to have employed, so far as they knew, competent men. But there is this to be said, that both in justice to his own company and in justice to the Haybridge Company (although I have very little sympathy with them), that when the report of Mr. Ashton was brought under his notice (the one on the 26th of December, pointing out that the flues of the boiler ought to have been renewed), and knowing what sort of boiler this was, he should have advised his company to discontinue the policy, which could have lapsed, I think, in May—at all events before the explosion—and in that respect we do think Mr. Mills is somewhat to blame.

"We are told that on this unfortunate man Owen, who was killed, the Coroner had an inquest, and the jury found that his death was '*caused by the accidental explosion of a boiler.*' Now in regard to that verdict, we do not know what evidence was before the jury, but we do know that the documents, the reports, and the policies which have been produced before us were not before them. No doubt on the evidence before them their verdict was quite a proper one. That, to me, shows the great importance of this investigation. It is gone forth to the world and to the public generally that this explosion was caused by an accident. It is only when the case comes to the consideration of the Board of Trade and when it comes to be decided by a court, half of which has scientific knowledge, that the question is really thoroughly examined, and we find that, so far from being an accident, it was almost a certainty that the boiler could not have been worked any great length of time without exploding, because the flue had lost its cylindrical shape. If that had been before the jury, the jury could not have said that this was an 'accidental explosion.' We think it important that all the facts should be laid before the Board of Trade, and also that steam users should be cognisant of them, as well as the public at large.

"We have to find Mr. Clement Groom very much to blame for the reasons which I have already stated. We are of opinion that the costs in this case must be a substantial sum. There is no evidence on which we can act before us that the people ever challenged the report of the Manchester Company by an examination, by any proper and competent men. Their attention having been called to the condition of the boiler, they should have either stopped it at once, unless they had an engineer who was of the same capability as the inspector. We think their conduct with regard to this particular boiler, and the general management of the works, has been disgraceful, and therefore we order them to pay to the solicitors of the Board of Trade the sum of £70 towards the costs and expenses of this investigation."

SHIPBUILDING NOTES.

ON the 13th ult. the Fairfield Shipbuilding and Engineering Company, Limited, launched the "Oldenburg," a steel screw steamer of 5,400 tons, built to the order of the North German Lloyd. The dimensions of the vessel are:—Length, 430ft. 10in.; breadth, 48ft.; depth, 33ft. The hull of the vessel is of Siemens-Martin steel, and the vessel has been built to the highest requirements of the German Lloyd. The engines are of inverted triple-expansion type, the cylinders being 31in., 52in., and 83in. diameter, the stroke being 4ft. 6in. The "Oldenburg" is exactly similar to the "Gera," which was successfully tried also on the 13th ult., when a mean speed of 13·8 knots was obtained, a speed exceeding the guaranteed speed by ¾ths of a knot.

ON the 13th ult. Messrs. R. Stephenson & Co., Limited, Newcastle-on-Tyne, launched from their yard at Hebburn the screw steamer "Cornhill," which they have built and engined for the Warworth Steamship Company, Limited. The vessel is of the improved well-deck type, the principal dimensions being:—Length, 203ft.; breadth, 31½ft.; depth, 14ft. 6in. The vessel has been designed to carry about 1,100 tons on a light draught of water. To the engine-room seven of Mason's patent skylights, and in the saloon skylight twelve of Mason's pivoted sidelights, have been fitted. The latter specialties have also been adopted elsewhere in the vessel. The engines are triple-expansion, indicating 700 h.p., and are fitted with all the latest improvements. The hull and machinery have been constructed

Digitized by Google

under the supervision of Mr. Alex. Taylor, consulting engineer, Newcastle-on-Tyne.

On the 20th ult. the steel screw steamer "Macduff," built by Messrs. W. Gray & Co., Limited, to the order of Messrs. J. Warrack & Co., of Leith, had her trial trip in the bay, off Hartlepool. She is a three-decked vessel, having a steel main deck, an iron upper deck sheathed with wood, and she takes Lloyd's highest class. Her dimensions are:—Length over all, 330ft.; breadth, 40ft. 6in.; depth, 27ft. Fine triple-expansion engines have been supplied by the Central Marine Engine Works of Messrs. Wm. Gray & Co., Limited, the cylinders being 25in., 40in., and 65in. in diameter, and the stroke of the piston 42in. The boilers, two in number and built of steel, are of large size, and work at a pressure of 160lb. per square inch. The ship and machinery have been built under the superintendence of Captain M. J. Butcher and Mr. M. A. Hall respectively. After the trial the vessel proceeded to Middlesbrough, where she will take in part cargo, making up the full complement at Glasgow and Liverpool, from which latter port she proceeds, under the command of Captain W. H. Hood, for Chinese ports, having been designed for that trade. The vessel was manipulated on her trial trip by her Chinese crew.

On the 26th ult. Messrs. Craig, Taylor, & Co. launched from their Thornaby shipbuilding yard, Stockton-on-Tees, a handsomely modelled steel screw steamer, of the following dimensions:—Length, 292ft.; breadth, 37ft.; depth, 20ft. 3in. The vessel has been built with a long raised quarter-deck bridge extending to and including foremast and fore-winch, short well, and topgallant forecastle. She is built on the web-frame principle, and has double bottom for water ballast all fore and aft and in peaks for about 600 tons. She will be fitted with four steam winches and Pepper's steam steering gear by Robert Roger & Co., Stockton; patent windlass, by Emerson, Walker, & Thomson Brothers, Gateshead; light-houses, Hastie's screw gear aft, and all modern improvements, so as to admit of rapid loading and discharging. The engines, on the triple-expansion three-crank system, are being constructed by Messrs. Blair & Co., Stockton, and the diameters of the cylinders are—21in., 35in., and 57in., with 39in. stroke; also two large steel boilers, 160lb. pressure. The vessel has been built to the order of Messrs. Vagliano Brothers, of London, for Messrs. Couppa & Co., of Marseilles, for their Mediterranean trade, and has been superintended by Mr. William Law, consulting engineer, of Liverpool.

On the 26th ult. Messrs. Sir Raylton Dixon & Co. launched a very fine steamer (the "Kintuck") which has been built to the order of the China Shippers' Mutual Steam Navigation Company, Limited, of London, and is intended to form one of their line of steamers for the tea trade. This vessel is one of the largest steamers yet built on the Tees, and has been constructed with very fine lines and large power, so as to attain a speed of 14 knots per hour. Her dimensions are:—Length over all, 373ft. 6in.; breadth, 45ft.; depth, moulded, 30ft. 3in. Her gross registered tonnage is about 3,700, and she will carry about 5,000 tons of tea. The engines are by Messrs. T. Richardson & Sons, of Hartlepool, with cylinders 32in., 49in., and 77in., having a stroke of 4ft., and will be of nearly 3,000 i.h.p. She was the last ship launched by Messrs. Dixon last year, making a total tonnage of 43,665 gross register for the twelve months.

On the 27th ult. Messrs. Ropner & Son launched a steel screw steamer, the "Calcutta City," of the following dimensions:—Length over all, 324ft.; breadth, 40ft. 6in.; depth, moulded, 23ft. 7in. This steamer has been built under special survey to class 100 A1 at Lloyd's, to the order of Mr. Ch. Furness, of West Hartlepool. She has a short full poop, in which is fitted accommodation for captain and officers, a raised quarter-deck, long bridge, short well, and topgallant forecastle, cellular bottom for water ballast. She is built on the web-frame principle, and, having very large hatches, is well adapted for carrying heavy cargoes. She will have four steam winches, two donkey boilers, Davis's steam steering gear, Hastie's screw gear aft, Emerson, Walker, & Co.'s direct steam windlass, &c., and all the latest improvements for a first-class cargo steamer. The engines are by Messrs. Blair & Co., Limited, of 950 h.p., with two steel boilers working at 160lb. This is the fifth steamer built by Messrs. Ropner & Son for the same owner.

On the 29th ult. there was launched from the shipbuilding yard of Messrs. R. & W. Hawthorn, Leslie, & Co., Limited, Hebburn, the "Mossoro," a steel screw steamer, for foreign owners, of the following dimensions:—Length over all, 215ft.; breadth, 31ft.; and depth, 15ft. She is built to the highest class at Bureau Veritas, under special survey, of Siemens-Martin steel, and has been specially subdivided by a large number of transverse bulkheads, which will add greatly to her safety. The vessel will be supplied with triple-expansion engines having a working pressure of 160lb. The vessel is intended to carry a large cargo on a light draught of water, and is specially adapted for ascending shallow rivers. She will be schooner rigged with two pole masts, and the whole of her fittings will be of the latest and most approved style. This is the first of four vessels being built by the same firm for similar trade.

The s.s. "Llanthony Abbey," which was built by Messrs. Ropner & Son, of Stockton, for Messrs. Pyman, Watson, & Co., of Cardiff, has just had her trial trip. The vessel is 290ft. long, 29ft. broad, and 20ft. 9in. deep. She has been engined by Messrs. Blair & Co., Limited, of Stockton, on the triple-expansion principle, her cylinders being 22in., 36in., and 59in. in diameter, by 39in. stroke, and working at 160lb. pressure of steam. The trip was very successful, everything working satisfactorily.

Notices of Meetings.

THIS WEEK.

Geologists' Association.—Friday, January 2nd, at 8 p.m. Papers to be read: "On Some Recent Sections at Dulwich," by Mr. T. Leighton and Mr. J. B. Ogle; "The British Tertiary Echinoid Faunas and their Affinities," by Mr. J. W. Gregory.

Royal Institution.—Saturday, January 3rd, Tuesday, January 6th, and Thursday, January 8th, at 3 p.m. Lectures on "Frost and Fire" (adapted to a Juvenile Auditory), by Professor Dewar, F.R.S.

NEXT WEEK.

Society of Chemical Industry.—Monday, January 5th, at 8 p.m. Paper to be read: "The Basic Copper Process," by Mr. Percy Gilchrist.

PRICES CURRENT, 31st December, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

" Australian	90	15	0	,,	91	5	0
" English Ingots	94	15	0			.....	

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues quiet—very little business taking place during the holidays. Owing to the small demand, values of raw copper keep very low, Chili bars being quoted to-day £52 10s. to £53 cash, with moderate trade. Manufactured, £66 to £67 "Strong," with slack demand.

Tin: Lower, the amount of business being very limited.

Lead: Quiet; last week's quotations unchanged.

Spelter continues very flat and prices are receding accordingly. The least improvement in demand would stop the downward movement, as stocks are unusually small everywhere.

The "Mechanical World" Pocket Diary and Year Book for 1891.—This handy little work has now attained its fourth year, and will be found of considerable use to engineers and draughtsmen. The contents of the book are practically the same as in previous years, except that the collection of rules and notes has been somewhat enlarged.

Calvert's Mechanic's Almanack for 1891.—We have had sent us a copy of this popular almanack, which is now in its eighteenth year of publication, and which is too well known amongst engineers and handicraftsmen to require any description on our part. We may, however, state that it appears to be generally up to date, and contains very interesting information.

The "Practical Engineer" Pocket Book and Diary for 1891.—We have received a copy of this useful annual, which combines a great amount of useful information for engineers and machinists, with a diary for the present year. In addition to the matter contained in last year's issue, we notice working drawings of various types of steam boilers, detail sketches of gas and steam engines, with their indicator diagrams. The little book is neatly bound, and will be found very useful.

We have received from the offices of the *Chronique Industrielle* a copy of the first part of a work by Ch. Casalonga, member of the Society of Civil Engineers of France, entitled "Mécanique Professionnelle," which is to be completed in ten parts. The book is replete with illustrations, and useful tables for giving the proportion of tools such as spanners, screw taps, and dyes, &c. It also deals at some length with the various metals employed in machine construction, their treatment in the foundry and forge, and with the various tools used in their conversion intomechanical appliances.

We have received a well-illustrated and complete catalogue of the engines, boilers, &c., made by Mr. R. Wolf, of Magdeburg-Buckau, Germany. Mr. Wolf has devoted particular attention to improvements in portable and semi-portable engines of modern construction, and, judging from the illustrations and tables given in the catalogue, has achieved excellent results. The works, we are informed, are provided throughout with the most modern type of machinery, and are lighted with the electric light from electrical machinery erected in the works.

HOME INDUSTRIES.

LONDON, 1st January, 1891.

The Money Market.—The demands incidental to the close of the year have made loans fairly dear this week, the more so as a large sum has been temporarily taken off the market to enable the India Council to pay for the acquisition of the South Indian Railway from the shareholders. Discount rates have remained steady at a fraction over 4 per cent. The holiday influence is still strong in the Stock Exchange, which is closed again to-day (Thursday). But though business has been on a very restricted scale, the tone of the markets has been firm and improving. The signs of a cessation of the Scottish railway strike gave rise to a considerable recovery in the stocks, and home railways generally rose after a few days' freedom from snowfall. Silver securities have been in request, largely on Continental account, Paris being anxious to sustain all markets to ensure the successful floating of the new French loan. Thus not only "International" stocks, but Argentines and silver securities have been supported with that view. Americans have been irregular, but with a steady undertone, and Canadian railway stocks have been in some favour. Mexican rails have undergone another sharp recovery, both on good traffic receipts and in consequence of the steadiness of silver. Miscellaneous securities were depressed by the failure in Dublin of a large operator interested in many of the more speculative of the newer industrial companies, and brewery shares also suffered through his delinquencies.

The Institution of Civil Engineers.—The seventy-third anniversary of the establishment of the Institution occurs to-morrow, the first formal meeting having been held at the Kendal Coffee House, in Fleet Street, on the 2nd January, 1818. The honour of having originated the Institution is often assigned to Smeaton, or to Telford, but the idea is erroneous in both cases. Smeaton died many years before it was thought of. Smeaton founded the Society of Engineers in 1771, but this Society, which still exists, and includes many of the most eminent members of the profession, has no connection with the Institution. The real founders of the Institution were William Maudslay, Joshua Field, Henry Robinson Palmer, James Jones, Charles Collinge, and James Ashwell, who had then just entered the profession. Telford became its President in the year 1820, and the Charter of Incorporation was granted on the 3rd June, 1828. Its membership now includes 5,953 persons of all classes, distributed throughout all parts of the Empire.

The Institute of Marine Engineers.—A meeting of this Institute was held on the 20th ult., Mr. F. W. Wymer, Vice-President, being in the chair, when an interesting paper on the "Efficiency of Air Compressors" was read by Mr. Joseph Williams, in the course of which he referred to the installations of pneumatic power distribution as being cleaner and safer than those where steam is the motive power. The author said that the fundamental principles of thermo-dynamics, as reasoned out by Professor Rankine and others, were true and accepted, but the practical working out of details based upon them was sometimes at fault, and to these he took exception. Papers read by Professor Kennedy, Messrs. T. B. Lightfoot, Coleman, Shone, and Donaldson were referred to in the course of the paper. The meeting closed with a vote of thanks to the author of the paper.

"Work" Exhibition.—On the 29th ult. an exhibition of various kinds of work was opened at the Polytechnic Institute, Regent Street, by Sir John Lubbock, M.P., Chairman of the London County Council. Many of the exhibits are made from designs published in *Work*, a journal issued by Messrs. Cassell. The jurors, who were appointed by the London Trades Council, awarded a gold medal to Mr. T. Coates for a working model of a steam fire-engine.

The "Electrical Review."—The offices of our American contemporary, of which Mr. Charles Ffrench is the London editor and manager, have been removed from Bridge House, 181, Queen Victoria Street, E.C., to Northumberland Avenue, Charing Cross, W.C.

German Wire Industry.—The Eschweiler Wire Industry Company, Limited (Germany), manufacturers of wire rods, rolled and drawn wire, wire nails, &c., have appointed Messrs. Künster & Co., 11, Queen Victoria Street, E.C., their sole agents in this country.

Business Announcement.—Mr. Thomas Tyrer, late partner in the firm of Messrs. May & Baker, manufacturing chemists, Battersea, has bought the goodwill and business of Messrs. Dunn & Co., manufacturing chemists, Stirling Chemical Works, Abbey Lane, Stratford, London, E. We are pleased to note that on the 5th inst., at 5 p.m., in the Lecture Theatre of the Chemical Society, Burlington House, a testimonial will be presented to Mr. Tyrer by his brother chemists, in recognition of his valuable services in the advancement of industrial chemistry.

Messrs. Broadwood & Sons.—At an entertainment given on the 27th ult. at the Westminster Town Hall by this firm to the children of their staff of employés, the electrical lighting was carried out by Messrs. Girdlestone, Tatham, & Co., of Davies Street, Berkeley Square, the current being gratuitously supplied by the Westminster Supply Company.

The Junior Engineering Society.—At a meeting of this Society, held on the 19th ult., a paper on "Artesian Wells" was read by Mr. P. G. Bowen. The difference oetween artesian and ordinary wells was first pointed out as consisting of the supply in the former case being obtained from a stratum below impervious beds instead of from surface waters as in the latter. The three principal modes of digging artesian wells by ordinary underpinning, by steining underpinning, and by drum curb sinking were then described. The wells were very seldom left unlined; bricks, dressed stones, and cast-iron segmental cylinders being the materials generally employed for their lining. The boring of wells was practised more on the Continent than in this country, but in 1885 two bored wells, each 6ft. diameter and 72ft. deep, were executed for the Southampton Water Works, the first taking 33 days, and the second 14 days in boring. The paper included an account of the difficulties encountered in artesian well work; of the systems adopted for increasing the water supply; the details of finishing off; the cost of boring; pumps; the comparison of deep well water with other waters; and the testing and softening processes.

MANCHESTER, 1st January, 1891.

The Iron Trade.—The present being practically observed as a holiday week, there is very little being done in this district in the iron market. Such transactions as are being effected are small in amount, and the prevailing weak tone throughout the main producing districts is having its effect on buyers here. Iron is being largely used, and consumers must come into the market sooner or later, but there is little disposition to buy so long as the prevalent depression exists. Purchases are mostly of small amounts, and prices are not fairly tested. Bar iron is also slowly bought, and there is a marked difference in the tone of this industry as compared with the corresponding period of last year. Still, there is a steady business doing, but the orders given are not large, and prices tend to weaken. Steel plates are steady, fair quantities being made and used. The general metal market is not so lively as it was, but both copper and brass are being well sold in sheets, tubes, and wire.

The Linen and Jute Trades.—There has not been any change of importance lately. The Scotch strike has affected business somewhat, the railway companies having declined to accept goods for points north of the Tweed without reservations in order to protect themselves against injury arising from delay. As far as consignments of linen goods from Scotland are concerned, the fact that such centres as Dundee and Kirkcaldy are on the coast enables manufacturers to counteract the effect of any possible stoppage in the system of inland transport. Many firms have already made use of the facilities thus placed at their disposal, and there has been a greater demand for tonnage from Liverpool in consequence. There is not much doing in the home trade, however, at this season, so that distributors are not inconvenienced as much as would have been the case had the strike set in a few months later. There is no change in quotations of piece goods, although yarns keep dear and manufacturers complain accordingly. Stocks in the hands of local merchants are not extensive, and this fact gives grounds for expecting an improvement in trade. Producers will thus be able to replace the orders which are now lapsing. Jute goods are quiet. The report current here to the effect that two of the largest firms in the linen thread trade are about to amalgamate is now denied, but as branch managers are not likely in any case to be taken into the confidence of the officials at the mills too soon there may be some truth in the rumour.

Technical Instruction.—The special committee appointed by the City Council to consider this subject has reported and recommended that the share of the city of Manchester of the grant in aid of the local rates, amounting to £11,500 for the current year, shall be applied to the purposes of technical education. It is pointed out that Mr. Goschen had expressed himself as of opinion that such an application would probably be approved by subsequent Governments. The grant would thus become practically perpetual, and in order to ensure this desirable end the recommendation of the committee has been made.

GLASGOW, 1st January, 1891.

The Coal Market.—The shipments of coals from Scottish ports, which were 112,785 tons in the week from 15th to 20th December, the week before the strike, and which were of about the same amount in the week from the 22nd to the 27th December, 1889, were only 68,082 tons in the past week. This falling off in shipments, amounting to upwards of 44,000 tons, has been due wholly to the railway strike. The prices of Newcastle coal have gone up considerably, owing to the transference of orders from Scotland.

The Railway Strike.—The serious block caused by the strike of the 21st ult. still continues. There is as yet no prospect of a decisive settlement. Spasmodic efforts at conciliation have been made at Edinburgh and Glasgow without result. The only important change in the situation is that a number of the employés of the Glasgow and South-Western Railway have gone back to work. The North British Railway traffic continues to be almost at a standstill as regards the goods traffic, and also to a large extent as regards the passenger traffic. The Caledonian Railway still finds serious difficulty with its goods traffic. The contest, however, has practically resolved itself into a struggle between the North British Railway Company and their men. It is impossible to predict what may be the course of events during the next few days. The men may gradually return to their work in small numbers, and so weaken the position of the strikers, or they may make up their minds to concentrate their attack upon a single railway company rather than divide their forces. The whole situation is fraught with much peril and annoyance to the travelling public, and, although occurring at a holiday time, with serious injury to industry.

Minerals.—The want of coal, in consequence of the suspension of goods and mineral traffic on account of the strike, has led to the premature closing of several public works for the holidays. It is calculated that not fewer than from 50,000 to 100,000 men are rendered idle for this reason for a longer period than would otherwise be the case. The pig iron market closed on the 31st ult. after the forenoon meeting, and will not reopen till the 5th inst. Business for the two days and a half of this week has been very quiet, though there is no falling off in price. The stock of pig iron in Connal's stores has now fallen to 587,652 tons, the decrease for last week having been 1,368 tons. Warrants were fairly firm in the beginning of the week, though even yet quotations are purely nominal, there being very little actual business done.

Rival Steamship Companies.—The Islay Steam Packet Company, which had been projected for the purpose of providing a steamer to ply between West Loch Tarbert and the island of Islay, will not now be formed, Mr David MacBrayne having undertaken to place a new steamer on the route.

(From our own Correspondents.)

LIVERPOOL, 31st December, 1890.

The Liverpool Water Supply.—"In consequence of the excessive consumption of water caused by the frost," the supply of water to the city and Bootle has had to be restricted, and it is cut off every evening until 6 or 7 o'clock the following morning. This has caused considerable inconvenience and consequent annoyance, especially as it is not evident why there should be an excessive consumption during the frost, as stated in the Town Clerk's notice. It is also a source of danger, for with the intermittent supply there is much more danger of the various pipes being frozen, thus preventing the escape of generated steam in domestic boilers. There have been several serious and fatal explosions of household boilers during the past week, and this action of the water committee is not conducive to safety. The supply of water to the city is from the old reservoirs and wells, the Vyrnwy water being still on the wrong side of the Mersey. The work at the tunnel is progressing slowly, and there are many complaints about the delay. Fresh arrangements have had to be made with the engineers, and instead of there being some return for the enormous outlay the expenditure keeps increasing.

LEEDS, 31st December, 1890.

Iron and Steel Trade.—Taken altogether the year 1890 has been a good one both for masters and employers, and, in fact, there has hardly ever been a year when all classes of workpeople have been more fully employed or better remunerated. It would, perhaps, be unwise to entertain the belief that the same amount of prosperity will be seen in the coming year, but some encouragement may be gathered from the opinion of Sir James Kitson, Bart. Speaking the other day in Leeds, Sir James said that notwithstanding the trouble in financial circles in London there is no reason to be despondent or to take a gloomy view of the future of manufactures in Leeds. In the year there has been a decline in prices, and at the present time the iron trade is very quiet, though a revival is expected before long. The steel trade has been busy during the year, and it may be noted that at the Leeds steelworks considerable extensions to the plant have been made. The briskness which has marked the engineering trade in 1890 continues, but most of the work is on account of old orders. There is again quietness in the agricultural machinery branch, and the cut steel and iron trade is not so good as it was.

The Coal Trade. — The revival which began in January has been maintained during the year, and now the prices quoted for the larger classes of coal are about what they were eleven months ago. A falling off in the demand for manufacturing coal is noticeable. The export trade has been steady throughout the year, and, excepting two months, there has been no difficulty in meeting the demand. The demand for gas coal has been uniformly good, and is now very brisk. During the year the miners have received an advance of 20 per cent. in their wages.

SHEFFIELD, 31st December, 1890.

Iron and Steel.—Business has been slack during the week here, although many firms are endeavouring to keep their machinery going. A large number of contracts for various engineering works at home and abroad will be cleared out this week so as to make room for a fair start on new contracts with the opening of another year. Again the home railway companies have favoured Sheffield with some large orders for tyres and axles, together with springs and other general forgings. It is worth mentioning here, however, that Messrs. Krupp, of Essen, Germany, have secured an order from the "Indian Midland" for railway material. This should make Sheffield manufacturers more

Digitized by Google

anxious than ever to turn out work of a quality superior to that of other manufacturers. Belgium also has secured a large portion of Sheffield work in an order for some wrought-iron buffer cases. These are welded up from ⅜in. plate to a cone with a narrow flange thrown off the base, the whole of the work being of a comparatively simple character. All the English tenders for this work were far above that of the Belgian firm who secured the order. Prices at present are as follows:—Laminated bearing springs, £10 to £12; volutes and other sections higher; waggon tyres, £10 to £11; locomotive tyres, £12 to £14; axles, £11 to £12, either Siemens or Bessemer, but the former is generally specified. No fixed price can be given for ordinary billets of steel, as these are sold to suit customers' requirements as to quality and temper. On the whole this has been a most prosperous year for Sheffield manufacturers. Prices have been low; indeed, far lower, in fact, than they should be, considering the enormous capital invested in the machinery and plant necessary to turn out the highest grades of work. As regards actual improvements in the method of producing steel, or in the reduction of cost, no progress has been made in the past year. Numerous extensions to works have been made, and the producing power has thus been vastly extended. The general prospects of trade for the new year are good.

COAL.—Colliery owners are endeavouring to get their men at work as soon as possible, as there is practically no fuel in stock, and most of the mines are now running. A vast amount of coal is being exported, and if the present output of iron continues fuel must increase in value again. House fire coal is in great demand, owing to the extremely cold weather. This winter has been one of the coldest known here, the thermometer having registered 22° F. below freezing.

THE NEW TRUNK LINE.—A number of surveyors have recently been engaged in the neighbourhood of Buxton in the interests of the promoters of the proposed East to West railway, and preparing the necessary maps, &c., to be deposited at Westminster. Should the work eventually be carried out it will be necessary to tunnel through the hill at Edgemoor to afford a direct route between Buxton and Macclesfield.

NORTH STAFFORDSHIRE, 31st DECEMBER, 1890.

THE IRON TRADE.—Work has been generally resumed at the mills and forges after the holidays. Prices show no signs of improvement, and the immediate outlook is not of an encouraging character. Pending the quarterly meetings but few inquiries or specifications are being received. The Chatterley Iron Company, in liquidation, last week paid its unsecured creditors off in full. It is understood that the company has made a good bargain with a North of England syndicate, having sold the whole of its property as a going concern, and that a company will shortly be floated with a capital of about £600,000 to work it.

THE POTTERY TRADE.—Mr. James, the arbitrator appointed by the manufacturers, objects to Mr. Mawdesley, the arbitrator appointed by the operatives, on the ground that, as an official of a working trades union, he would be naturally biassed and act more as a delegate than as an arbitrator. This appears a comparatively trivial objection, and one which should not be allowed to jeopardise a peaceable settlement of the wages question in the trade.

LEICESTER, 31st DECEMBER, 1890.

COAL MINING.—The collieries in this coalfield are all very busy, many of them being at work six days a week. The demand continues pressing, and as stocks are clear, there will of necessity be full employment in coal-getting. The coal owners have this week made a further advance in prices all round.

WOOL SPINNING AND YARN TRADES.—There was a quiet trade doing in the local wool trade just before Christmas, but the occurrence of the holidays has naturally much interfered with business. There is a very healthy tone pervading the market, and the prospects of trade in the new year are on all hands considered encouraging. Buyers are cautious, and there is no disposition to speculate. Stocks are small, and in few hands. Much more confidence prevails on all sides. Deep-stapled fleeces make 23s. to 24s. per tod; superior quality, 24s. 6d. to 25s. 6d. per tod; choice lots, with large proportion of Shropshire fleeces, 26s. to 27s. per tod. Spinners are mostly idle this week, and engaged in machinery repairs. There is a small amount of new business, and a fairly brisk time is anticipated after this week.

HOSIERY TRADE.—The cold weather gave a great impetus to this department, and a busy time was experienced right up to Christmas. The demand for heavy woollen underwear and gloves was very brisk, and has cleared the stocks in the warehouses. Business is being gradually resumed this week, and a very good time is anticipated in the opening weeks of the new year.

BOOT AND SHOE TRADE.—Some firms are making a long holiday in the factory department, and have not yet resumed business. The snow has cleared stocks of heavy goods, but its long continuance has somewhat retarded the placing of orders for spring goods. Still there will be rather more work to commence on next week than for some time past. Leather merchants are doing a small trade only.

SWANSEA, 31st DECEMBER, 1890.

TINPLATES.—It would seem as if the cycle of prosperity for this trade was measurable in decades, for, to find so successful a period as that through which we are passing, it is necessary to go back to 1880, and again to 1870. This, however, only refers to results of operations, and not to the magnitude of the trade itself, for this has been increasing at so large a rate that, whereas, in 1870, 100,000 tons of tinplates were exported, the amount was more than doubled in 1880, and this will again be more than doubled for 1890, as the exports for this year are sure to exceed 450,000 tons. Prices, which saw a low level from April to July of the year now closing, during which period IC cokes barely reached 13s. 9d. per ton, have, under the influence of the excitement caused by the McKinley Act, recovered the position they had attained at the commencement of the year, and are now at 16s. 6d. to 17s., with a hopeful outlook. Close upon 100,000 boxes were received into warehouses during the week preceding Christmas, a quantity which is the highest on record. The Caerleon Tinplate Company has been registered, with a capital of £5,000 in £5 shares.

THE COPPER WORKS.—Some twenty workmen have had to be discharged from the Morfa Copper Works owing to the scarcity of orders for yellow metal. It is stated that during the recent strike at these works the company had to refuse an order for 7,000 tons of yellow metal, which, had they been able to accept, would in all likelihood have made the present action unnecessary.—The strike at the Cape Copper Works, Neath, which affected upwards of a thousand men, was put an end to after six weeks' idleness, brought about by a dispute over the question of helpers engaged in wheeling the metal to and from the furnaces. Masters and men have met each other half way.

BARROW-IN-FURNESS, 31st DECEMBER, 1890.

HEMATITE.—There has been a want of activity in the hematite pig iron trade during the week, and sales have been checked by reason of the Christmas holidays. Prices are again easier, and warrants are at 53s. 7½d., and makers are asking 54s. 6d. for mixed numbers of hematite warrants, and 54s. for No. 3 forge. Stocks have again been reduced during the week to the extent of 980 tons, making a decrease of 169,474 tons up to the 29th inst., and leaving the stocks still in hand at 211,065 tons. An additional furnace has been put in blast at Askham, near Barrow, which makes the number in blast fifty, compared with fifty-six twelve months ago.

STEEL.—Although the prospects of the steel trade for 1891 are not such as will justify the belief that trade will be as brisk as in the year now closing, it is noteworthy that some fairly good orders have been received for rails at about £4 17s. 6d. per ton for heavy sections. The local and general demand for steel shipbuilding material is fairly brisk, the requirements of local shipbuilders being especially good. Plates are down at £6 7s. 6d. per ton, angles at £5 12s. 6d., and boiler plates at £7 10s.

SHIPPING.—The amount of pig iron and steel shipped from West Coast ports during the past year represents 1,042,429 tons. The amount shipped during 1889 was 1,064,511 tons, showing 22,082 tons decrease on the year.

SHIPBUILDING.—The shipbuilding works are almost closed, and a complete resumption of work will not take place until the 5th prox. Builders have a very big programme of work before them, and it is expected that a very large tonnage will be launched, and that the engines built for the ensuing year will show an enormous indicated horse-power.

MIDDLESBROUGH, 31st DECEMBER, 1890.

PIG IRON.—The market yesterday was very dull, and the attendance on 'Change was small. This dulness of trade is intensified by the holidays, and there are few people prepared to do business. There is little inquiry, and the policy of buyers is a waiting one, for they believe that prices will be worse instead of better in the new year. There is little done in speculative operations, for as prices continue to fall persistently there is nothing to be made out of transactions in warrants. Merchants would take 42s. 6d. per ton for prompt f.o.b. deliveries of No. 3 G.M.B. No business is done in warrants, but the prices nominally are 42s. 3d. cash buyers and 42s. sellers. In hematite iron East Coast brands are quoted at 55s. per ton for Nos. 1, 2, and 3 makers' iron. The stock in Connal's store here is going quite the opposite way from what was expected, for it has increased 4,442 tons since the 22nd inst. and 14,207 tons since the 30th ult., the quantity held on the evening of the 29th inst. being 104,336 tons.

SHIPMENTS OF PIG IRON.—The shipments of pig iron are very poor, and up to the 29th inst. reached only 56,996 tons, as against 75,849 tons during the corresponding period in November, but 16,673 tons more than up to the 29th of December last year. Altogether over the whole year shipments will have fallen off at least 160,000 tons, as compared with 1889. Of the pig iron shipped this month 31,116 tons have gone to Scotland, 5,717 tons to England and Wales, 5,717 tons to Germany and Holland, and 14,279 tons to other foreign countries. The chief falling off is in the shipments to Germany and Holland, who took 15,439 tons last month, and to Scotland, who had 36,119 tons.

MANUFACTURED IRON AND STEEL.—There is no change in these in the prices; indeed, very little business is being done. As a set off to the dulness of the trade it is comforting to note that Messrs. Bolckow, Vaughan, & Co., of the Cleveland Steel Works, have just got orders for steel rails—17,000 tons for the Indian State Railways and 10,000 tons for a German railway. The latter is rather remarkable, considering the influences which practically shut us out from the German market.

WAGES.—The Cleveland ironmasters having notified the blast furnace men that they cannot entertain an application for the eight hours system, and that they intend to ask the men to submit to a material reduction of wages, a joint meeting of the executive of the Cleveland Miners and the Cleveland Blast Furnace Men's Associations was held, when it was resolved:—"That, on the intimation from the iron-masters and mine-owners for a substantial reduction in wages, it will be greatly to the interest of both bodies of men that they act in unison to avoid such reduction, and that neither party will agree to accept such reduction without the consent of the other."

THE LATE MR. T. RICHARDSON.—Mr. Thomas Richardson, who was head of the well-known shipbuilding firm of Messrs. T. Richardson & Sons, of Hartlepool, died on the 29th ult. He had represented Hartlepool in Parliament for many years, having been first elected in the year 1874.

NEWCASTLE, 31st DECEMBER, 1890.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending the 27th inst. amounted to 81,177 tons, being a decrease as compared with the corresponding week last year of 206 tons.

THE HOLIDAYS.—The observance of the Christmas holidays has caused the whole of the works in the district to be laid idle during the latter half of last week, and in some instances the suspension of operations is intended to be continued over this week also. Many firms take advantage of this holiday period to carry out a thorough process of stocktaking, and to this circumstance is doubtless due the prolongation of the stoppage in the cases referred to.

RAILWAY MEN'S WAGES AND HOURS OF WORK.—The claim of the railway servants in the employ of the North Eastern Company in Newcastle, for a rearrangement of the working hours in some departments and an advance of wages in others, having been met in a conciliatory spirit by the directors, a conflict which would have been disastrous to the commercial interests of the district has been avoided. Wherever any reasonable grounds for a change in the existing conditions of work could be put forward concessions have been made, and as a settlement which appears to be satisfactory to all parties has been arrived at, it is to be hoped that such a sudden disruption of traffic arrangements will not again be threatened.

OVERTIME IN ENGINEERING SHOPS.—A committee representing different sections of engineering operatives have sent a notice to the employers intimating that from January 1st the working of overtime on new and old work shall be disallowed, excepting under conditions which involve a large increase in the rates of pay for the same. It is not as yet known what action the employers may take in reference to the matter.

ENGINEERING.—A new engineering specialty, which is likely to become popular, is being introduced in this district by Mr. W. F. Snowdon, 32, Side, Newcastle. This is the "Dodge patent wood split pulley," manufactured by the Dodge Manufacturing Company, Indiana, U.S.A., for whom Messrs. Isaac Braithwaite & Son, Kendal, are the principal English agents and importers. Several special advantages are claimed for this specialty, and the agents are so confident of its superiority that they offer a free trial before purchase.

SHIPBUILDING.—The total tonnage launched on the Tyne this year amounts to 235,062 tons, which, as compared with last year's output, shows a decrease of nearly 47,000 tons.

DUNDEE 31st DECEMBER, 1890.

FLAX AND JUTE TRADES.—The railway strike, which has now lasted ten days, has seriously interfered with business. At this season of the year there is generally very little business. Manufacturers are now taking stock of the trade for the last twelve months. The retrospect is not a bright one, but there is not, on the whole, much room for complaint. In some departments the extent of business has not been so great as could be wished, and prices are somewhat weak, but, on the other hand, the price of the raw material is lower than it was last December. Dundee has imported during the year 24,153 tons of flax, and 4,887 tons of tow and codilla. Last year the imports were—Flax, 26,396 tons, and tow, 4,789 tons. These figures, it may be remarked, were much below those of 1888. As to prices, the quotation for the best quality of flax shows little or no change, but tows, which were £25 and £27 last December, are £23 and £25. Flax yarns, which fetched 1s. 4d. last December, are now selling at 1s. 2½d., and 6lb. tow yarns have fallen from 2s. to 1s. 8½d. Flax canvas, which brought 9¾d. to 10d. twelve months ago, is now sold at 9d. to 9¼d., and merchant navy has declined from 7½d. to 7d. The jute import for the year shows an improvement—238,835 tons, against 222,710 tons. During the latter half of the year some qualities have declined in value as much as £5 per ton. Fine jute yarns show a considerable decline in price for the year. The closing price last December was from 1s. 7½d. to 1s. 8d.; the quotation to-day is 1s. 5d. to 1s. 6d. Hessian cloth 40in. 10½oz., which closed last year at 2d. to 2 1/16d., closes this year at 1⅝d. to 2⅛d.

THE WEST HIGHLAND RAILWAY.

I.

THE railway now being constructed from Helensburgh, on the Clyde, to Fort William, under the shadow of Ben Nevis, is one of the most considerable engineering enterprises in progress in this country at present. The line is 100 miles long, and is carried through a country of mountain and moorland, in parts of which there are even no roads for the transport of the material of construction. Passing as it does through a country famous for opportunities for fishing, shooting, and deer-stalking, the line must ultimately become very familiar to English sportsmen as well as to the ordinary tourist. Throughout its length the railway traverses scenery whose picturesqueness is not excelled in Scotland. Immediately on leaving Helensburgh the line plunges into the beautiful woodlands at the entrance to the Gareloch, and, following the north shore of that loch—whose still waters are famous among shipowners as the Clyde resort for the adjustment of compasses—it rises by a gradient of 1 in 60 to the "col" at the head of the loch, from which it drops again to Loch Long, and, winding along its eastern shore, reaches Arrochar, from which it crosses the isthmus separating Loch Long from Loch Lomond, and by Tarbet and Ardlui passes on by the unrivalled scenery of the queen of Scottish lakes to Crianlarich, where it crosses the existing Callander and Oban line by a fine viaduct. By the opposite side of the valley to the Oban line it follows the contour of the hills, sweeping round them in ample curves, and rising at an easy gradient until it reaches Bridge of Orchy, from which it crosses the western end of the moor of Rannoch, and so on to Fort William. While it has been thus necessary to indicate the general features of the line, we illustrate at present, in Figs. 1, 2, 3, and 4, only the section from Crianlarich to about four miles beyond Tyndrum, leaving the other sections for subsequent treatment. This section is fully twelve miles long, and, although the utmost ingenuity has been exercised by the engineers in availing themselves of the contours of the hills, several viaducts have been necessary. The largest of these is at Crianlarich, where, emerging from Glen Falloch, the line first crosses the Callander and Oban Railway, and then sweeps across Strath Fillan, until it again winds along the hillside. The Crianlarich viaduct, shown in our illustration (Fig. 1), consists of five spans of 35ft. each, and extends to a length of 200ft. At Crianlarich there is a short loop line which connects the West Highland with the Callander and Oban Railway. The next viaduct is at Inverhaggernie, where the line crosses a mountain stream. A deep and narrow gorge at Auchtertyre is crossed by another viaduct, now in course of construction, and shown in Fig. 2. This viaduct will consist of five spans, the centre span being 101ft., and the remainder 55ft. each. The height of the centre of the viaduct will be 80ft. The material out of which the piers are built is quarried from the bank of the stream over which the viaduct is built. The spans are constructed of lattice girders. The line from Auchtertyre to Tyndrum follows the contour of the hill very closely, and is made in the simplest manner, the material cut from the hill being in some places simply tipped over the shelf, only about half the width of the line having thus to be excavated from the hillside. Very ample provision is made for water-courses, which form the principal sources of danger to lines and roads in these Highland regions. The railway, indeed, as it follows the contour line, consists for the most part of short lengths of bank between small bridges, there being very few cuttings, and no tunnels whatever. The absence of tunnels is quite an unusual feature in a mountain line. When the line reaches the end of the range, near the upper end of Glen Lyon, the longest glen in Scotland, and opposite Beinn Doireann, a mountain over 3,500ft. high, confronting the head of Strath Fillan, it takes a sweep round the horseshoe-like configuration of the group of hills, of which Beinn Doireann is the highest and most north-westerly, and Beinn á Chaisteil is the central and most northerly. Two viaducts here enable the line to pass at the same level from the contour of one hill to another, and yet to another. This part of the line is not yet constructed, but the viaduct will be one of the most picturesque on the line. On the side of Beinn Doireann the railway is carried to Bridge of Orchy, where the section begins which stretches over Rannoch Moor, in regions where the conveyance of material is as difficult as in an uninhabited country. This, as well as the other sections, will form the subject of subsequent articles. The line is a single one throughout. The rails employed for the permanent way are 75lb. steel rails, and the girders used in the viaducts are being made and erected by Messrs. Finlay & Co., Motherwell.

The engineers of the line are Messrs. Formans & MacCall, Glasgow, and the contractors are Messrs. Lucas & Aird, of London. We have to express our acknowledgments to both firms, and to their representatives on the works, for the facilities generously given us for visiting and illustrating the railway.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 399, Strand, London, W.C.*

Industries:

FRIDAY, 2ND JANUARY, 1891.

THE INDUSTRIAL OUTLOOK FOR 1891.

THERE is a not very easily formulated, but nevertheless wide-spread, impression that the prospects that lie in the future are by no means so satisfactory as the trade outlook at this time last year. This view is not, it must be admitted, without some, if not very adequate, justification. The usual tests of the immediate future of business are the export and import returns, the railway traffic returns, and the range of prices. The first of this series indicates the prospects of our foreign trade, the second the position and prospects of our business at home, and the third the character of the demand in relation to the supply. The foreign trade of 1890 was considerably better than in the year 1889. Imports have diminished, but there has been a more than corresponding expansion of our exports. The balance, on the whole, is favourable to the net result for the year. But the amount of business done during the second half of the year has fallen off in comparison with that of the previous year, and the fall was all the more marked as the year proceeded, until in November there was a falling off in our export trade of about a million and a half, and in our import trade of more than four millions sterling, as compared with the totals for the same month of 1889. If the same rate of decrease were continued over the twelve months, it would mean that the foreign trade would show a diminution of not less than 66 millions sterling at the end of the year, which would, of course, represent a shrinkage of the most serious character. There is probably no sufficient reason to believe that the total trade of the year will suffer to anything like this extent, but that there will be a reduced business in the immediate future appears to be placed beyond much doubt. So far as our internal trade is concerned, there are evidences of a decline in many directions. We have the falling off that is already apparent in our railway traffic. During the second half of the year there was an increase of only 2·7 per cent. in the receipts from this source, whereas, for the first six months of 1890, there was an increase of 4·2 per cent. It is true that up to the end of the year 1890 there has been an actual increase in the traffic carried, and in the receipts therefrom, as compared with the previous year; but the increase steadily diminished as the year advanced, until at the close of the year it had practically reached a vanishing point. There have, of course, been exceptional circumstances to account for this falling away, but the main reason has been that the general condition of trade had become less stable, and that in many industries profits had become more attenuated.

One of the most serious difficulties that appear to lie in the pathway of industry is the continued high price of the raw materials relatively to the prices realised for the finished articles. Throughout the year 1890 there has been a very large demand for nearly all descriptions of raw material. As a consequence, fuel, iron ores, and other raw materials have been selling at extraordinarily high prices. The average price of the imported iron ore, which, by the way, reached the exceptionally high figure, for the year, of about 4½ millions of tons, was about 16s., being several shillings above the average prices of the six years ending with 1888. It has been much the same with coal and coke, which have been selling at fully 60 per cent. more than the average prices of the same period. Labour, again, has advanced all round, so that the wages paid to-day are probably 35 to 50 per cent. more than the average wages of three or four years ago. The prices of the manufactured articles, such as pig iron, rails, shipbuilding tonnage, and other leading products, have failed to keep pace with the greater cost of raw materials, so that manufacturers, instead of being in a better, are in very many cases in a worse, position than they occupied a few years ago. The result is seen in the suspension of manufacturing operations in the pig iron trade of Scotland, in the increased development of syndicates designed to control prices and production, and in attempts to reduce the rate of wages all round. Another rock ahead is the labour question. The workmen have up to the present time participated fairly, as a rule, in the generally improved conditions of trade. They have, however, lost a great deal of the gain that would have come to them from this source by their frequent strikes, since the rise in prices caused by restricted production was only a temporary one. But they are generally earning much better wages to-day than they did a year or two ago. Should the prospects that appear to be imminent come to be fully realised, wages must fall, but it is seldom that they are allowed to fall without some sort of resistance on the part of the workmen. The Board of Trade has ascertained that during the year 1889 there were not less than 1,145 strikes of all kinds, most of them for higher rates of wages. This system of "killing the goose that lays the golden eggs" is not by any means new; but it is none the less unfortunate that the same experience is always repeated under similar conditions. The years 1889–90 have been years of plenty, and employers could not in many cases decline to give higher rates of wages. We are now, however, entering upon what appears likely to be relatively, if not absolutely, lean years, and it will be well if the working classes learn to adapt themselves thereto.

Apart from the influences which operate at home, and which, like the poor, we "have always with us," there are influences beyond our own control that threaten to interfere with the prospects of our commerce in the future. The most important of these is probably the tendency on the part of foreign countries to draw still closer the bonds that bind them to the Protectionist movement. The McKinley Tariff Act, so long as it lasts, will undoubtedly have an unfavourable effect on our trade relations with the United States. The annual value of our trade with that country is about 140 millions sterling, of which 44 millions represent exports from Great Britain. This sum is only 47 millions less than the value of our total annual trade with the colonial possessions of Great Britain, including India, so that it is a fairly important factor in our trade accounts. The new Tariff Act may not affect our imports very materially, but it has already affected, and is likely to affect still more in the future, the value of our exports. In Russia, France, and other countries, the general tariffs are now under revision, and the outlook from this point of view is far from reassuring. We may, indeed, be able by-and-bye to adapt ourselves to the altered tariff conditions of these countries, as

Digitized by Google

we have done before, but the immediate effect is likely to be a certain dislocation of industrial affairs, involving both loss and trouble.

On the other hand, there is a brighter side to the somewhat sombre picture that we have so far painted. England has industrial worries and difficulties, but she does not stand alone. Most of the leading nations of the world are in much the same case, without possessing to the same extent that combination of skilled labour, English grit and steadiness, financial resources, and accumulated experience that have all along kept England in the forefront. In Continental countries there is a tendency to reduce the hours of labour and to raise the rate of wages. In the United States, the McKinley Tariff Act, by making imports dearer, will certainly not make labour cheaper. There is but little proof that we are likely to yield up our industrial supremacy to other nations. It is true that the United States now make more pig iron, steel, and some other productions than we do, but they make these almost exclusively for themselves. England continues to hold her own in neutral markets, and it is at least a consoling reflection with which to begin the new year, that we have just finished the best year's business that has ever been recorded in industrial history.

THE SCOTTISH RAILWAY STRIKE.

The Christmas holidays in Scotland have been marked by a strike of railway servants so extensive as to cause an almost complete stoppage of goods traffic and a very considerable derangement of the passenger service. Indeed, the Scottish railway system has been almost paralysed from the morning of Monday, the 22nd ult. The leading ground of the complaint made by the men is the duration of the working day. They do not, they say, object so much to the average number of hours of work, as to the length of the spells of it, and they allege that they have placed their grievances again and again before the companies without effect. The managers of the companies state, on the other hand, that they have never indicated any indisposition to deal with specific complaints. The meaning of this is, of course, that the railway managers refuse to recognise the Railway Servants' Association, or to treat with its executive as the ostensible representatives of the men. However, on the morning of the 22nd ult. upwards of 3,000 men came out, and by the 27th ult. at least 8,000 were out, although the figures as stated by the different parties vary considerably. The railway companies were completely taken by surprise. They had not made—perhaps they could not have made—provision for carrying on their traffic without the services of the strikers, and the result, for a time, was complete chaos. Signalmen and engine-drivers cannot be produced in numbers at a day's notice, and thus those who remained in the service of the companies were compelled, it is said, to work, practically, from Monday morning to Saturday night, with the briefest intervals snatched for sleep. The wonder is that, in spite of the reduction in the train service, some deplorable calamity has not occurred.

The demands of the men are formulated in the following terms:—

"1. That a universal ten-hours day be the maximum day's work for all grades of the service.

"2. That the custom of reckoning hours of labour by an aggregate fortnight's work be dispensed with, and that each day stand for itself.

"3. Time-and-a-quarter pay for overtime.

"4. Time-and-a-half pay for Sunday duty; such to be reckoned from 12 p.m. on Saturday to 12 p.m. on Sunday.

"5. That eight hours be the maximum for yardsmen, shunters, ground pointsmen, and locomotive men, and others engaged in busy shunting yards.

"6. That more cabins at present working on the twelve-hours system be placed on the eight hours per day system.

"7. That a universal agreement for regular annual holidays be put into practice.

"8. That the running of trains on the "trip" or contract system be abolished.

"9. That a mileage system be arranged for passenger and goods trains.

"10. Owing to the whole time of all grades being at the disposal of the companies, it be a condition of service that men be guaranteed a week's work, and when sent out for duty at any time, or waiting orders by instruction, a full day's pay be paid, and the custom of booking men off duty for periods during the running of their maximum day's work be abolished."

The shipping delays on account of the strike have already caused immense loss. In the case of some valuable goods, these have been carted into Glasgow for distances of over twenty miles in order that they might be shipped. It is perhaps too soon, however, to estimate the extremely serious issues opened up by the strike. There are some disputes which the public may regard with indifference, because its interests are not seriously menaced, or because the combatants are so nearly equally matched in strength that they may be left to fight out their own quarrel in their own way. But a railway strike is not a strike of this kind. The position which a great railway company occupies nowadays is that of practical monopolist of public transit. So far as the legislature is concerned, every facility has been given to the development of our railway system. The result of all this has been that the railway companies have become endowed with most extensive and progressively valuable privileges. The claim, therefore, that the public may, on occasion, intervene in the affairs of a railway company seems fairly clear. Not only this, but, since the irregularity or otherwise of the way in which the companies exercise the function of public carriers is a matter of supreme public moment, it may become an absolute duty for the public to interfere, apart altogether from any special legislative enactments, by using the weight of its opinion. Yet it is difficult for the public to do this effectively. A railway company is a delicately organised machine, depending not upon the strongest, but upon the weakest of its integral parts. The growth of the railway system has thus been at once a growth in size and in close interdependence in organisation. When from any cause any part goes quite out of gear, the whole machinery stops or becomes a ruin. The occurrence of this strike, and the by no means remote probability of a repetition of it ere long, shows how tremendously potent for evil a railway strike may become. It is futile to expect the companies to surrender to demands that they have already repeatedly rejected; it is equally futile pathetically to beseech the men to return to their work. The plain course is, since they cannot agree, and since their disagreement is a public peril, to mutually refer their differences to a neutral arbiter. The higher the standing of this arbiter the better. It is out of no sentimental idea that "peace is better than war" that we have persistently pressed this remedy for industrial disputes, but because it is becoming increasingly plain to every one who looks even a little way ahead, that the policy of leaving two brute forces to fight it out between them is fatally wrong economically. The more highly developed our industrial system becomes, the more dependent do we become upon labour. Thus, if it be partially true that the forces of capital are becoming concentrated, it is even more true that the forces of labour are becoming concentrated. On one side we have massed a more or less cohesive group of labourers, and on the other a more or less cohesive group of capitalists. These together carry on production, national or international. The great mass of the public, so far as these groups taken separately are concerned, have interests distinct from them, and thus, unless the public is perpetually to be buffeted by these contending factions, some means must be devised to prevent the frequency of this appeal to brute force.

Two methods at once suggest themselves—that of legislation, and that of voluntary regulation. Legislation may be in one of two directions: it may be in the direction of re-enacting the abandoned anti-combination laws, or it may be in the direction of compelling reference to the Courts of Justice in all cases of disputes about wages, hours, or terms of service. It is reported that the railway companies contemplate making some attempt in the first-mentioned direction. It is, however, rather unlikely that Parliament will reverse the legislation of the past twenty years. The other direction—viz., that of compelling in certain events appeal to the Law Courts—might, perhaps, be attempted with success; but the practical difficulties in the way of devising a measure which would be just to every interest are very great. The method of voluntary regulation remains as by far the best and most elastic. It must not be supposed that we would countenance happy-go-lucky interference and gratuitous advice by people who have no means of forming any reliable judgment on intricate details of administration. The haphazard method just now current, where obstinacy and eagerness to cultivate the goodwill of the public go hand in hand, is responsible for the existence of these irresponsible advisers. What we mean is a formal arbitration by some arbiter of undoubted standing, who should have before him both pleadings and evidence.

Even if this strike fail altogether in its specific aim, it has shown what a dangerous power the railway servants have when they choose to use it. We would not defend for a moment the action of the men in leaving their employment without notice, nor would we pronounce offhand an opinion as to the severity of their work, but the fact of the strike is enough to show that their grievances should be made the subject of careful inquiry, and that any settlement that does not take these into account cannot be otherwise than merely temporary.

THE COTTON INDUSTRY.

A well-known politician is reported to have said a few days ago that millowners are firmly convinced that it is only a question of a very few years before Manchester will lose the India and China markets. If this opinion be correct, it is a sufficiently serious matter for Manchester, and, indeed, for Lancashire generally, to demand the most careful attention of all concerned, so that if the state of affairs indicated cannot be averted it may at least be brought about so gradually that those who are mainly affected may have had time to have fitted themselves to the altered conditions. It must be admitted that the circumstances are very threatening, especially as regards India, for even at present the Bombay spinners of cotton yarns have virtually driven Lancashire out of India, Japan, and China for the coarser yarns, and efforts are constantly being made to produce finer numbers, and every year shows fresh encroachments on Lancashire. Twenty years ago there were only 400,000 spindles in all India. During the last half-dozen years, however, the rate of increase has been very great. In 1885 the number of people employed in the cotton industry in India was 67,000, while at present there are about 102,000. In 1887 there were 103 cotton mills in the country, with about 2¼ million spindles, consuming 2½ million cwt. of cotton. Now there are 137 mills, with 3,274,196 spindles, consuming 3½ million cwt. of cotton, and the majority of these mills are paying good, and in some cases very good, dividends. The number of power looms in India in 1887 was 18,536, now there are 23,412. During the five years 1880–84 the total exports of twist and yarn from India were valued at £7,800,000; during the following five years 1885–89 they mounted to a total of £18,230,000, or an increase of about 230 per cent. There has been a substantial increase in manufactured cotton goods over the same periods, viz., from £9,700,000 to £12,440,000.

These figures are sufficient to cause serious thought to our Lancashire manufacturers, and make them inquire into all the circumstances connected with the progress of the cotton industry at home and abroad. They know perfectly well that they cannot expect India to be kept as a preserve for their special benefit, but they have a right to expect that the conditions of competition shall be fair, and this cannot at present be said to be the case. By our Factory Acts our cotton mills can only work fifty-six hours per week. In India, on the other hand, much greater freedom is allowed to the manufacturers, and the cotton industry there seems to be passing through the same stages as it did in its early days in this country. Of course, the competition with Lancashire prevents the immense profits being made which were made in Britain early in this century, but the longer hours and the cheap labour, which is to a very large extent that of women, children, and young persons, enable the manufacturers not only to withstand competition, but also to realise what in these days are considered very fair profits. We cannot interfere directly with the conditions of labour in foreign countries, nor can we attempt to make our colonies and dependencies mere appendages to our manufacturing concerns, but it is only reasonable that conditions should be equalised as nearly as possible, and this, not merely as an act of justice to our manufacturers, but also in the interests of humanity and of the natives of India. We may rest assured that a reaction will come, and that it will be impossible for us to govern the vast population of India unless the great mass of the people of that country are satisfied that we are acting in their interests, and not in the interests of foreign capitalists, who are extracting from the great mass of the people great gains by keeping them in a state of abject poverty and unremitting toil.

The workpeople in India are beginning to combine and to demand reasonable hours, and the same conditions as the workers in this country. The Bombay Mill-hands' Association recently presented a petition to the Viceroy setting forth their grievances, and asked that it be forwarded by him through the regular channel. The authorities will have their hands full with this matter during the coming session, and it will be their duty to weigh carefully all sides of the question. Our manufacturers should take care that their opinions are heard and considered. It may be urged that the transit charges of the raw cotton to England, and of the yarn and manufactured goods to India, are sufficient to account for the advantages of the Indian mills, but those

Digitized by Google

who have examined carefully the details of the problem assure us that this is not the case, and that our disadvantages as regards transit have been reduced very much of recent years. This contention is, we think, proved to be correct by the fact that America grows her own cotton, like India, she makes her own machinery to a very large extent, is provided with high-class skilled labour, and is also nearer the cotton fields, and yet she has to pay at least 35 per cent. duty upon the commonest cotton fabrics in order to keep us out. The problem is still further complicated by the silver question.

A consideration of all the circumstances of the case shows us that the whole cotton industry of the country is in a state of unstable equilibrium, and the very causes which gave it prominence and developed it are now tending to transfer it to India and other countries where labour is cheap, hours long, and materials abundant. The manufacturers have, therefore, the right to ask our legislators that they shall, as far as possible, remove everything which tends to make the competition unfair.

THE NORTON FITZWARREN RAILWAY ACCIDENT.

In the Board of Trade report of this accident, Colonel Rich remarks:—"This very serious collision was caused by the signalman at Norton Fitzwarren station cabin having forgotten that he had placed the down goods train from Bristol on the up main line. He ought to have put the goods train on to one of the branch lines. He placed it on the main up line at 1.10 a.m., fourteen minutes before the up special train arrived. The driver of the goods train stated that he whistled to call the signalman's attention and to intimate that he wanted to go, immediately after the broad-gauge pilot engine returned on to the main down line about 1.19, and that he changed his head lamp from red to green about 1½ minutes before the special arrived; but as his regulations direct that he shall keep the red light exhibited so long as he is not on his proper line, I cannot understand why he changed it at the time he said he did. If he had exhibited the red light, it might not only have drawn the signalman's attention to the train being on the up line, but the driver of the special would probably have observed it after he passed the up home-signal, when there was time to stop the special train by applying the continuous brake. I consider that the driver of the goods train's negligence, in disregarding the company's regulations, contributed to the catastrophe. The regulations further provide that the guard of the goods train shall go himself, or send his assistant, to the signal cabin, and remind the signalman of the position of his train. The guard did not go, nor did he tell his brakesman to do so, and by his neglect he also contributed to the collision. The signalman had been on duty 4½ hours; the driver of the Bristol goods, 7 hours 40 minutes; the guard of the Bristol goods, 7¼ hours. I recommend that all stations where there is much shunting, or where stopping trains are liable to be set aside for fast trains to pass, should be provided with refuge sidings at the proper side of the railway; and in addition to the present rules, which are very good if carried out, lifting bars may sometimes be advantageously used to lock the signals of the line on which trains have to wait for 'Line clear,' as collisions, consequent on the signalman forgetting that he has a train standing at his home or advance signals, are not uncommon. I am informed that many signalmen put one of their flag sticks in the spring catch of the signal levers of the line that is blocked, to prevent their forgetting that a train is waiting to proceed, and pulling off the signals of the line that is occupied. I would suggest that a slide bar, a loop, a wedge, or some other mechanical contrivance, marked 'Train waiting' should be fixed to the levers in the cabin to do this, and prevent these levers from being pulled by mistake."

TRADE PROSPECTS WITH ZAMBEZIA.

An address was given on Wednesday, the 17th ult., at the London Chamber of Commerce, by Mr. E. A. Maund, on the trade prospects of the territory which has been newly styled Zambezia, which is now being opened up by the Chartered Company. The climate of Mashonaland is good, though, as in all tropical regions, precautions have to be taken in selecting the sites of buildings and in dieting. The soil is very fertile, and can grow wheat, potatoes, cabbages, carrots, and other vegetables, fruits of all kinds, rice, and indiarubber. Mr. Maund considers, from his personal experiences on the spot, that there will be a ready sale to the natives of cotton goods (blue and white "limbo"), coloured beads, trade knives; guns, powder, and lead for hunting; axes, American ploughs, and old clothes. There will also soon be a great demand for corrugated iron houses. The gold alone in Mashonaland would develop Zambezia into, perhaps, the richest acquisition of the empire, and there would be a rush to the new colony unexampled in the history of South Africa. It is chiefly on account of its great richness in gold that we must look for the commercial value of Zambezia. The country can doubtless, both climatically and agriculturally, support its probable large white population. To and from the busy mining centres, soon to spring up, commerce must flow. The development of the gold industry must be pushed forward on sound commercial principles. There will be no necessity for expensive white labour, except as overseers, mine captains, and gangers, and for dealing with machinery. The author suggested that what is wanted in our colonies are Schools of Mines under State direction. Victoria now has one at Ballarat, and South Africa wants one. The Chartered Company should institute one, for it will shortly require so many experts, competent assayists, geologists, and managers, that without efficient and skilled men investors may be misled. Zambezia is fast assuming the character of an organised colony under the administration of the Chartered Company, and when the rush comes it will find a strong executive ready to receive and regulate it, and thus order is wisely assured.

THE LATE MR. WILLIAM JOHN.

We regret to have to announce the death of Mr. William John, the well-known naval architect, on the 26th ult., at Madrid. Mr. John's professional abilities were of a high order. He was a native of Pembroke, and was one of the first students of the Royal School of Naval Architecture and Marine Engineering, and was cotemporary, as a student, with Mr. W. H. White, Director of Naval Construction; Dr. Francis Elgar, Director of the Admiralty Dockyards; Mr. R. Sennett, formerly Engineer-in-Chief of the Royal Navy; and Mr. A. J. Durston, the present Engineer-in-Chief. Mr. John made the calculation for the first curves of stability for a ship ever constructed. He calculated the stability of the ill-fated "Captain," and pointed out the dangers to which she was liable, a short time before she was lost. After passing out of the Royal School of Naval Architecture with the highest honours attainable, he was for several years employed in the Construction Department at the Admiralty. He left the Admiralty service, in 1872, to join that of Lloyd's Register Society, and there he distinguished himself by his grasp of the problems that arose in connection with the mercantile marine, and by his success in dealing with them as the scientific assistant to Mr. Martell, the Chief Surveyor. His treatise on "The Masting of Vessels," first brought out in the form of a report to the Committee of Lloyd's, is reckoned the standard authority on the subject, and has been officially translated into the languages of the leading maritime nations. Mr. John contributed numerous papers to the Transactions of the Institution of Naval Architects, all of which are marked by great power of thought and clearness of conception of the subjects with which they treat, and one of his most recent successes was the carrying off, in a competition open to the naval architects of the world, of the prize of $25,000 offered by the United States Government for a design for the warship "Texas," now building at Norfolk, Virginia. In 1881 Mr. John left Lloyd's to become general manager of the Barrow Shipbuilding and Engineering Company. During the last two years he has practised in London. He was a member of the late Board of Trade Committee on life-saving appliances in ships, a member of council of the Institution of Naval Architects, and a Fellow of the Royal School of Naval Architecture and Marine Engineering. Mr. John was forty-five years of age.

THE LATE MR. LANT CARPENTER.

Mr. William Lant Carpenter died on the 23rd ult., at his residence, Harlesden, near London. He was a son of the late Dr. W. B. Carpenter, the eminent physiologist and author of works on mental physiology. His grandfather was Dr. Lant Carpenter, of Bristol, and his aunt was Mary Carpenter, who was well known for her work in connection with reformatories, and for her efforts to improve the condition of the people in India. Mr. Lant Carpenter was a mechanical engineer by profession, and was manager of the school of electrical engineering in Princes Street, Hanover Square, W. He had earned a considerable reputation amongst men of science, and was much interested in science teaching. He was a warm supporter of the Recreative Evening Schools Association, and other similar philanthropical institutions.

Letters to the Editor.

IMPROVEMENTS IN THE MANUFACTURE OF NITRIC ACID.

To the Editor of "Industries."

Sir,—In a recent number of *Industries* Mr. Blount asked me to explain certain statements that have been published in a German paper, and I answered briefly that, for the want of time, I could not answer all criticisms, which are based upon evident misunderstanding, but that out of courtesy to Mr. Blount I would, as soon as possible, explain those points which have been misunderstood.

Now, the first and most essential point for many industries is that with my system of manufacture I do not produce weak nitric acid at all, but only such as will have an average specific gravity of 1·500. This has been quite overlooked in the criticism, and I was reminded of the well-known practice to regulate the heat so as to have a temperature of 80° when distilling acid of 44° B. and over, and a temperature of 120° when acid below this strength is made. If anybody can afford to get acids of all strengths, and to sell them separately, he may do as he likes, but the average manufacturer prefers to have acid of no other strength than the one he wants.

When I said that with my system the distillation can be carried on as hot as may be liked, I was speaking to experts, who could understand that I do not work a blast furnace, but want to get nitric acid with as little nitrous acid as possible. Naturally there are comparatively great differences in temperature, as, for instance, between 80° and 120°; but whereas everybody else carries his work on as slowly as possible, I can drive mine as fast as required, as the acid results are always good.

It will not do to say that any dark acid which may result can be discoloured. I have no difficulty in "bleaching" nitric acid even in two hours, although generally it takes as many days, but it is always a costly and inconvenient process, which slightly weakens the acid, and why resort to it if we can do without it?

I also am told the startling news, that there are such things as "receivers" (or "pots"), which are very good for condensation, and that 5 of them are sufficient for a charge of 6 to 7 cwt. of nitrate. The plant of retorts, which I showed, makes 36 cwt. of nitric acid (1·500 sp. gr.) *daily*. In order to make this according to the above plant 16 retorts (charged with 6 cwt. of nitric each), with 80 pots and 4 towers, would be necessary, because in order to have perfect condensation in 5 pots very slow work is necessary. A charge cannot be worked off in less than 24 to 28 hours, and therefore, allowing time for the cooling of the retorts and recharging, only every 48 hours can a fresh charge be made, which is the general practice.

Now if I do the same work with 4 retorts, 4 batteries, and 1 tower, in 24 hours only, and do not get any weak acid at all, there is surely some improvement. And every manufacturer will see at once that 16 retorts and 80 pots will take three times as large a building as my system, and that the cost of such a plant must be at least three times that of mine, and certainly much more than £1,500, as is believed. I have now had through my hands a good many plants of different factories, all over the world, and I have never found a single one to contradict my statement.

In order to show the work of my system, I give below the record taken out of a day's work. The acid was drawn into carboys as it was formed, and each examined separately. They showed:—1st carboy, 1·530; 2nd, 1·550; 3rd, 1·550; 4th, 1·515; 5th, 1·510; 6th, 1·485—average sp. gr., 1·525.

As regards the mastic used for jointing the pipes, I have no difficulty whatever; the special mastic which I use becomes as hard as a brick, and never cracks. If the circumference of the joints is taken into consideration, I have rather less difficulty than others have with the smallest number of pots, and I have recently made some improvement. Besides which, all the joints are of a smaller diameter than usual, so that there is less risk of leakage.

In conclusion, I may repeat that the system works very satisfactorily indeed, and will be soon erected in other parts of the world, and that by people having very long experience in the matter.

Yours, &c.,
Oscar Guttmann.

OUR BIG GUNS, AND HOW THEY ARE MADE.

To the Editor of "Industries."

Sir,—General Braddock's last words were, "Whoever would have thought it!" and it does not need high imagination to conceive some high official at Woolwich making the same remark over the cracked rings of the latest failure in big guns. The fact, I fear, is that the military mind does not change much, and that very much the same dulness of insight and apprehension which proved fatal to Braddock still rules the construction of our heavy ordnance.

At a meeting of the Royal United Service Institution, held on March 3rd, 1879, at which Sir Henry Lefroy, K.C.M.G., R.A., F.R.S., presided, and at which Major-General Younghusband, R.A., was present, the late Dr. C. William Siemens read a paper, partly on the "Application of Steel to Military Purposes," in which he gave clear warning that he anticipated fractures in the rings of guns where they are shrunk on in the way now in vogue. He says, after pointing out the error of shrinking rings on as tight as possible upon bodies which are subsequently to be expanded by heat when used, "if a steel gun or a ring forming part of the same was put into a furnace, heated up to a temperature of, say, 600° C., and the inside was subjected to cooling action while the outside was maintained at the temperature of the furnace, a distribution of stress would result which would be highly advantageous to the strength of the gun. The chilling of the inside surface of the ring or gun would cool the metal towards the inside circumference. This metal could not shrink, nor would the inner diameter of the gun diminish, because the diameter would be determined by the mass of metal still in the heated condition. The vacancies produced in the cooled metal would be filled up by the inflow of metal from the heated mass outside,

Digitized by Google

resulting in equilibrium of the metal at the diameter originally due to the heated mass, and the temperature will gradually vary from, say, 100° C. inside to 600° C. outside. If the gun be afterwards taken out and allowed gradually to cool, but without stopping the cooling action from within, the whole mass will cool down to the minimum temperature. If we imagine the ring to consist of a succession of concentric cylinders, each cylinder would acquire a tensile strain due to its previous temperature, which, being a minimum on the inside and a maximum on the periphery, there would result a distribution of tension throughout the mass, being negative or compressive in the interior and more and more tensile towards the exterior. Then, when the full pressure of powder gas was active, the strain upon each portion would be equal, and the resulting strain would be opposed by the whole elastic strength of the metal. The internal portion of the tube would, with such a mode of construction, have no other function to perform than to resist the abrasion that is necessarily going on in the gun. This question is now very much before the scientific public, and therefore I thought it well to bring before you my own view of the matter."

The foregoing appears clear and simple enough, and is an important utterance by one of the leading, if not the leading man of his time, calling the attention of the officials present to an eminent danger threatening matters in their charge. That no notice whatever was taken of the said utterance by either the chairman or General Younghusband in their replies to and discussions on the paper in question certainly appears remarkable, and I think the easiest explanation is that they did not understand the import of what Dr. Siemens said. At all events, from then until now no attention has been given to Dr. Siemens' advice, for rings are shrunk on as tightly as may be considered proper on one another, with a hardened steel tube inside, and when the inside layers expand from the heat of the ignited gunpowder and burst those outside, every one is surprised, and says, "Who would have thought it?" like General Braddock—who would have made a good "Woolwich authority" had he lived now.

It seems to me that by your publishing the above facts you will go some way towards stopping the present childish waste of public money. That the Arsenal officials will ever change their methods until they are compelled I suppose no one now expects, and that they are capable of carrying out Dr. Siemens' suggestions is not to be looked for at all. They do not yet believe in gaseous fuel for reheating wrought iron, and it is matter of common knowledge that they caused a large contractor to give up the use of Siemens' furnaces, as they thought the gas injured the iron. Therefore it is not to be expected that they could themselves design the furnace and gas apparatus which I know Dr. Siemens contemplated. However that may be, I think I may call upon them to explain why they have for nearly twelve years ignored such plain, easy advice from such a high authority as Dr. C. W. Siemens.

Yours, &c.,
R. R. Gubbins,
Late Lieut. 4th Batt. 60th Rifles.

Belvedere, 26th December, 1890.

BAKU AND ITS INDUSTRIAL PROSPECTS.

To the Editor of "Industries."

Sir,—Since I wrote to you last I have been looking around, and find that the glass which is used here, either for windows or bottles, comes from Northern Russia. Consequently it costs a high price. For empty wine bottles 3d. (or 10 kopeks) per bottle is charged. I find that at the north of the Caspian Sea there is plenty of sand to be got of nearly pure silica. There are also plenty of salt and sulphur in the immediate neighbourhood, yet there is no glass works near here. It strikes me that if some one with capital were to come here he might get a fortune in a short time in that line. He would require a few skilled workmen, and the rest would be easy. The Russians in this part are not skilled workmen in the highest sense, but they are very good at imitation, and a few good men would soon set a glass works going.

I believe I have the privilege of erecting the first trussed roof out of flat timber in the district. It is one of 35ft. span. Usually two round poles, about 9in. diameter at the larger end and 7in. at the other end, answer for a tie beam, and for 35ft. span a wooden pillar is put from the ground to the ridge. The principals are spaced about 7ft. centre to centre.

Flat timber is difficult to get here, and, as I said in my last letter, a saw mill with machinery for moulding would, without doubt, be a profitable investment. As it is, the timber in flat planks has the bark on each edge, and is dressed to dimensions by the axe. A carpenter is well equipped if he possesses an axe and a small frame saw. There is, therefore, a considerable waste of timber. There is a large number of casks used here, all of which are made by hand.

Yours, &c.,
Engineer.

Baku, 6–18th December, 1890.

ROYAL METEOROLOGICAL SOCIETY.

At the usual monthly meeting of this Society, which was held on the 17th ult., Mr. H. F. Blanford, F.R.S., Vice-President, being in the chair, the papers named below were read. The following is a brief abstract of each:—

1. "Note on a Lightning Stroke presenting some Features of Interest," by Mr. R. H. Scott, F.R.S. On January 5th a house near Ballyglass, Co. Mayo, was struck by lightning, and some amount of damage done. A peculiar occurrence happened to a basket of eggs lying on the floor of one of the rooms. The shells were shattered, so that they fell off when the eggs were put in boiling water, but the inner membrane was not broken. The eggs tasted quite sound. The owner's account is that he boiled a few eggs from the top of the basket; the rest were "made into a mummy," "the lower ones all flattened, but not broken."

2. "Note on the Effect of Lightning on a Dwelling House," by Mr. A. Brewin. This was an account of the damage done to the author's house at Twickenham on September 23rd.

3. "Wind Systems and Trade Routes between the Cape of Good Hope and Australia," by Captain M. W. C. Hepworth. The author was of opinion that the best parallel on which commanders of vessels navigating the South Indian Ocean between the Cape of Good Hope and the Australian Colonies should run down the longitude is between the 41st and 42nd parallels during the winter months, and between the 45th and 46th parallels during the summer months.

4. "Report on the Phenological Observations for 1890," by Mr. E. Mawley. Taking the year ending August, the weather of the autumn, winter, and spring, and of the first summer month could scarcely have been more favourable for vegetation, while that of July and August proved altogether as unpropitious.

5. "The Climate of Hong Kong," by Dr. W. Doberck. This was a discussion of the meteorological results at the Hong Kong Observatory and at the Victoria Peak during the five years 1884–88.

THE PROPOSED CHANNEL BRIDGE.

The *Times* Paris correspondent, writing on the 26th ult., gives the following interesting information regarding the proposed Channel Bridge:—

"The preliminary scheme for the construction of a bridge between France and England was prepared from incomplete and, to some extent, old hydrographic and geological documents. As the previous surveys did not appear sufficient to the promoters of the enterprise, it was resolved to make a complete exploration of the Straits of Dover in order to collect precise information with reference to the hydrography and sea bottom of the Straits. With the authority of the Minister of Marine, the management of the surveying company was intrusted to M. Renaud, hydrographic engineer, to whom was added as assistant M. Duchanoy, mining engineer. An analysis of their report is published to-night. In the preliminary scheme the bridge started from the Cran aux Œufs, south of Cape Grisnez, went on over a bottom which sank to 55 metres as far as the Colbart Bank, touched the north point of the Colbart and the southern part of the Varne, and finally reached Folkestone. Between the Colbart and the English coast the bottom is of moderate depth.

"The operations were commenced on board a Boulogne tug, the 'Ajax,' which was supplied with the necessary apparatus for sounding and boring. A beginning was made in that part of the Straits lying between the Varne and Boulogne known as the French Channel. Between the Varne and Folkestone the surveyors went on board an English vessel, the 'Jubilee,' placed at their disposal by Sir Edward Watkin, President of the Submarine Tunnel Company. The English Admiralty having intimated that it would prefer the observations near the British coast to be made from an English vessel, the desire thus expressed was complied with. Soundings and borings were taken from July 3rd to September 1st. From the observations made, M. Renaud has come to the conclusion that the most advantageous line for the bridge is not that fixed on in the preliminary scheme. The line he recommends is straight. It starts from a point 350 metres north-east of the light to the west of the South Foreland, and it terminates 300 metres north-east of the entrance of the tunnel near Cape Grisnez. Its length is 33,450 metres. The greatest depth of water met with on the line was from 50 to 51 metres, a depth extending only over a distance of 1,700 metres. The length of the bridge along the line now proposed is shorter by 5,150 metres than that suggested in the preliminary scheme. Moreover, it avoids depths of 55 metres, and those over 50 metres extend only over a comparatively short distance. The soundings show that the submarine soil is solid everywhere, and that there is in no place mud or soft clay. The study of the fauna made for the survey by M. Giard, professor at the Sorbonne and director of the Laboratory of Marine Zoology at Wimereux, near Boulogne, and M. Bouner, sub-director of the same laboratory, proves that between Cape Grisnez and the Colbart only a rocky bottom occurs. The apparatus only brought up animals which live on rocks, and none which live in gravel, sand, clay, or mud. From this it is concluded that there is no chance of the Straits ever being silted up. As regards the bridge itself, the line being shortened and the height of the piles diminished in consequence of the greater shallowness of the water over which it passes, considerable diminution of expense is secured as compared with the first scheme. Instead of four millions of metres cube of masonry there will only be three-and-a-half millions. About 50,000 tons of metal will also be saved. Lastly, there will be 92 piles instead of 112, and of these 92 piles 17 will be sunk in depths of 30 to 40 metres, 31 in depths of 40 to 50 metres, and the others in depths of less than 30 metres.

"In summing up the advantages of the new scheme, the report says the new line gives greater facility for sinking the piles, a better shelter from the wind and seas from the south-west along the French coast, a slight lowering of the height of the bridge, and a considerable diminution of the masonry and weight of the metallic structure."

THE MANCHESTER SHIP CANAL.

We gather from an official report that, with reference to the damage done to the works of the Canal by the recent floods, the Mode Wheel Locks at Barton Aqueduct were cleared out in the course of a few days, and that since then the other locks at Barton, Irlam, and Latchford have been pumped dry, and masonry and concrete work resumed. The cuttings near Trafford Hall, at Barton, Stickens Island, Hulme Bridge, Davey Lulme, Irlam, and Latchford are now emptied, and excavation has recommenced. Concrete work and masonry have sinced been pushed on with vigour, except when it has been interfered with by the frost. The cutting at Partington will be pumped dry in about sixteen days, while at Pomona one portion of the dock has been cleared of water and excavation resumed. The second portion of the dock will be emptied as soon as the frost is over. It is stated that the masonry and concrete work at the various docks and locks has withstood the severe test in a most satisfactory manner, and that the completed portions of the slopes of the cuttings, the temporary bridges, and railways damaged by the flood have now been restored. The brickworks at Thelwall, which were flooded, and which are capable of producing upwards of 450,000 bricks per week, have been ready for work for some days past. The volume of water which passed down the Irwell during the time of the late flood was considerably in excess of that at the time of any flood since the great flood of 1866; and it is conjectured that, had it not been for the large works now in course of construction, the effect of the flood would have been nearly as serious as in that year.

Reviews.

The Art of Electrolytical Separation of Metals, &c. By G. Gore. London: "The Electrician" Printing and Publishing Company, Limited. 1890.

The author sets himself the difficult task of treating this exhaustive subject systematically. Electrometallurgy is generally treated in one of several ways. The purely scientific man regards it as an interesting mixture of electricity, chemistry, and thermodynamics, with side lights of osmosis and dissociation, and gives it an interminable and somewhat unreadable literature of its own: the electrical engineer troubles himself little about such things, and thinks of back pressure, electromotive force, capacity, and resistance; while the practical electroplater still goes on passing the current of seven Smee cells through his solutions. Dr. Gore's work is chiefly useful as a large collection of information of the greatest value to the practical electrometallurgist. Probably few electrical engineers realise how much more they might know about actual practice in such processes as the electrical refinement of copper. Dr. Gore's book contains a full account of almost everything that has been done by previous workers. The scientific part of the book is weak, but the rest is extremely good.

Fehland's Engineers' Pocket-Book for 1891. Berlin: Springer.

This is the latest edition of the well-known pocket-book of engineering and other formulæ. We would strongly advise engineers who work from pocket-books not to rely on English formulæ solely. Engineering practice varies in different countries. The best thing to do is to learn from all sources, and to adopt good points from other countries.

Force, as an Entity, with Stream, Pool, and Wave Forms. By Lieut.-Col. W. Sedgwick, R.E. Sampson Low, Marston, Searle, & Rivington. 1890.

The author tells us in his preface that he has endeavoured to treat the subject of force from an engineer's point of view, or in a simple and practical way. The remainder of the preface, however, dispels any hope which we might have founded upon this statement, for, in the short space of ten pages of large print, we are introduced to such widely divergent subjects as the Enormous and Irregular Growth of Novels, Carlyle's Theory of the Infernal and Celestial in Man, Drunk-

Digitized by Google

enness and Opium-eating, the Survival of the Fittest, the Mission of the Anglo-Saxon Race in the Development of Civilisation, the Death of General Gordon, the Principal Religions of the West and of the East, and the advantages and disadvantages of Home Rule for Ireland. On the last page of the preface the author modestly informs us that as a literary production the book is of the poorest, and, after perusing the volume, we have no hesitation in expressing our complete agreement with him on this point.

The work is divided into ten chapters, bearing the following headings:—Introduction, Streams and Pools of Force, The Form of the Atom, Chemical Combination, Electricity, Physics, Mechanics, Solar Systems, The Origin of Life, Humanity. With regard to the author's theory of Force, which we suppose is to be considered the main subject of the book, we must allow him to speak for himself by giving a few extracts, as we have been utterly unable to form any definite idea of what he means. The following, culled from the Introduction, is supposed, as far as we can understand, to represent the teaching of Faraday and Rankine:—"If, then, gravitation, which is, as we know, an attractive force under which points approach one another, is a substance taking the form of lines of force, then heat, or some other form of repulsive force, under which points recede from one another, must likewise be a substance, and take the form of lines of force also." We are then told that "if force is in reality a substance, it must be a fluid, able to lay hold of particles of matter and transport them along with it as it flows, much in the same way as water in a river lays hold of particles of silt and sand and carries them along." The author then remarks:—"But fluids have three principal forms—the *stream*, or current; the *pool*, or accumulation; and the *wave*. And if force is a fluid, then we may conclude that lines of force are in reality streams or currents of force, thread-like in their minuteness, and, indeed, far finer than the finest thread we can distinguish with the aid of the microscope, but otherwise exactly corresponding to the streams or currents in rivers, lakes, or seas. While centres of force plainly are pools or lakes along the course of the lines of force, corresponding, on a minute scale, to the pools or lakes along the course of a river."

The author's Cosmic theory appears to be that all the phenomena of the universe are due to the action of two kinds of forced action, namely, attractive force, emanating from the Deity, and repulsive force, emanating from the Evil One. Ultimately the repulsive forces will be compelled to beat a retreat, and the attractive forces will reign supreme, or, in other words, Good will triumph over Evil.

Much of the last chapter—that on Humanity—is very amusing, but we cannot find time or space to seriously notice it.

THE STEAM ENGINE, CONSIDERED AS A THERMODYNAMIC MACHINE. By James H. Cotterill, M.A., F.R.S., Professor of Applied Mechanics in the Royal Naval College. London: E. & F. SPON. 1890.

This is said to be a second edition, revised and enlarged, of Professor Cotterill's standard work on the steam engine which was published in December, 1877, but it would be more correct to speak of it as a third edition of a small work which he published in 1871, and which was eagerly studied by students of thermodynamics. Up to that time the only text-book published in England, which treated of the theory of the steam engine as founded on the science of thermodynamics, was that by Professor Rankine on the steam engine and other prime movers, which is written in such a condensed, and in many cases abstract form, that it is very hard reading for all except very advanced students. Professor Cotterill's notes were drawn up to assist students of engineering and others interested in steam engines in following Rankine's methods, and these were all that were available for six years, till he published his complete treatise, of which the book we are noticing is the second edition. In this book it was attempted for the first time to study more completely than had hitherto been done the process of the conversion of heat into work in steam engines. Although the book has now been several years out of print it took a very long time to exhaust the first edition, a fact which is a commentary on the low state of engineering education in Britain. Books which are specially written to pass Science and Art Department or Board of Trade examinations are sold by the thousand, whereas those which aim at giving a thorough knowledge of fundamental principles take years to exhaust even a first edition.

Professor Cotterill says that he has undertaken the preparation of a new edition with great reluctance, feeling that, considering the progress made since 1877, a new book rather than a new edition of an old one would be required to deal with the subject in a manner at all commensurate with its difficulty and importance. On consideration, however, it seemed that, the ground occupied and the method of treatment being in many respects different from those adopted by others, the book might, with some changes and additions, still prove useful. The author says that this opinion would not have been altered if he had had the advantage of being able to consult the two able American treatises by Professors Peabody and Volson Wood (both of which we have reviewed), which appeared some time after the greater part of the volume was in type. We quite agree with Professor Cotterill that there is room for a treatise such as his, which treats of what may be called the physics of the subject, and explains the phenomena which occur in the use of steam, without bringing the results into the shape which are immediately useful in practical calculations—that is to say, for an educational book, which, while it leads in the direction of practical applications, is intended primarily for the purpose of elucidating phenomena. In the present day teachers and students alike are too much in the habit of looking to what pays directly, wholly forgetting that in education, as in commerce, what pays ultimately and best is not always what pays most at first. In the last edition of his work, Professor Cotterill said his chief object was to facilitate the study of Rankine's work, and, by the employment of fresh experimental evidence, to carry it on a few steps beyond the point at which Rankine left it. This object was attained in a very satisfactory manner, and he produced a work which was highly prized by all real students. We may be allowed to say, however, that some of the methods employed were rather cumbrous, and apt to weary students. Like many teachers who aim at only employing elementary mathematics, he made his demonstrations more lengthy, and in many cases more difficult to understand, than if he had boldly assumed a greater knowledge on the part of his readers. The graphic representations of physical phenomena adopted by the author were a great advance on previous methods, and were of much assistance in enabling the students to understand the real nature of these phenomena.

In the present edition, considerable additions and improvements have been made on the original work. The first nine chapters have been re-written, with additions to illustrate more fully the principles of thermodynamics, and further notes regarding them are given in the appendix. These chapters, in our opinion, contain the most useful explanation of the laws of thermodynamics to be found in any English treatise, and are well worthy of being studied even by those who do not intend becoming engineers, so that their notions of the subject may become more real, for the majority never get beyond a very hazy idea as to their meaning and scope. Chapter VIII., on "Losses of Efficiency in Heat Engines," should be studied with special care, as it gives a very clear idea of the manner in which heat is used in engines. The following chapter, on "Clearance and Wire-Drawing," is more special in its nature, and may be studied with advantage, both by students of physics and engineering. Chapters X. and XI., which treat of the action of the sides of the cylinder, and of experiments on steam engines, have been entirely re-written. At the time of the publication of the previous edition of the book, although it was obvious that cylinder condensation was the rule in steam engines, and its absence the exception, the want of experiments on the subject prevented an opinion being formed as to the law which it followed. Since that time, however, considerable attention has been paid to the subject, especially by the experiments of Messrs. Muir and Willans and Major English. Professor Cotterill has adopted some of Major English's conclusions, and has deduced a theory of the conduction of heat in cylinders. From this he has worked out a simple formula, which gives a fair approximation to the amount of steam wasted in single-expansion non-jacketed engines by initial condensation and other causes. This formula, of course, involves a constant to be determined by experience for each type of engine, but the values of the constant in a large number of examples of engines of widely different types appear fairly consistent. Our space will not allow us to discuss that formula at present, but we ask our readers to compare Professor Cotterill's method with that adopted by Mr. Bodmer in the articles on "Steam Engine Economy," which recently appeared in our columns.

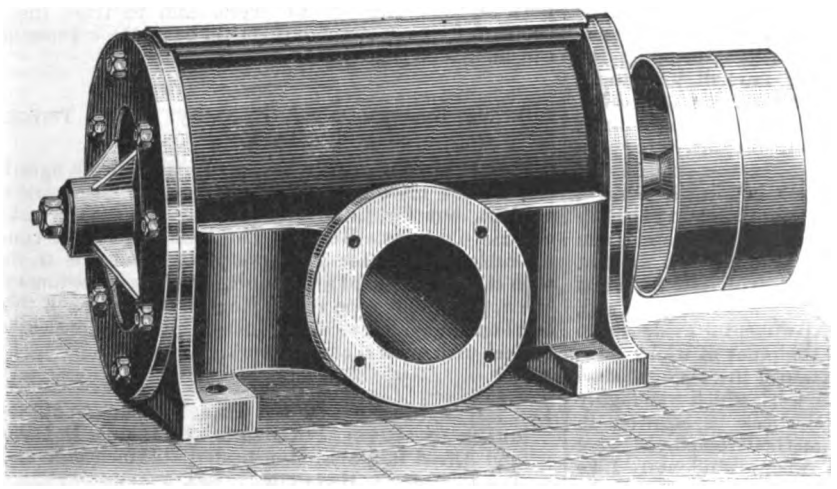
The last chapter in the book is the one which will possibly be read with most interest by engineers, as it gives details of experiments on steam engines, and states the conditions of economical working. The action of feed-waters, a part of the subject which has been much neglected, is also dealt with. The few observations made on compound engines and on jacketing are intended chiefly as suggestions, as the author thinks that no real progress can be made until the question of cylinder condensation in a single-expansion non-jacketed engine has been more thoroughly studied. That may be true, but still we think the author might have done more to redeem the intention he expressed in the preface to the last edition of the work, to add chapters on the working of compound engines, and to the modern theories about superheated steam. No book on the steam engine can be considered even approximately complete without an explanation of the action of multiple-expansion engines, while the subject of superheating is one which, if properly studied and experimented upon, might obviate in many cases the multiplification of cylinders. We hope that before another edition of the book is required Professor Cotterill will have sufficient information on both of those subjects to enable him to treat them pretty fully, even suppose it should be at the expense of causing his book to appear in two volumes.

LUMIÈRE ELECTRIQUE. J. P. Anney. Paris: TIGNOL. 1890.

This is an elementary handbook, specially designed, not for the intelligent public, nor for the enthusiastic student, but for those who have to deal with private electric light installations. The book deals with considerable minuteness with everything that has to do with the arrangement and running of electric machinery. We hope we may soon see an English translation of this excellent work. A second volume is promised, which is to deal with central station work.

THE RIVER IRWELL AND ITS TRIBUTARIES: A MONOGRAPH ON RIVER POLLUTION. By George E. Davis and Alfred R. Davis, Manchester. Manchester and London: JOHN HEYWOOD. 1890.

The second half of the title of this little book is a fair indication of its nature and scope. In the course of their practice as consulting chemists, the attention of the authors has been directed to the subject of river pollution, and the means for its prevention or mitigation. For a study of this kind the Manchester district affords ample opportunity, industries of the most diverse character contributing to the defilement of its watercourses, and full advantage has been taken of this circumstance.



The River Irwell, rising near Bacup, receives tributaries that drain an area of 180,000 acres. On its way to Manchester, it is largely used for manufacturing purposes, and on leaving the city at Throstle Nest Weir is in a highly polluted condition. Since it is probable that at this point it will eventually flow into the Manchester Ship Canal, the reach of which between Barton and Manchester will, as the authors say, "act as one vast settling tank," the need for some improvement is tolerably obvious. Having premised the necessity for reform, the authors proceed to give numerous analyses of the Irwell and its tributaries in their normal condition of flow, and also in flood and drought. Some of these results are sufficiently startling. In the case of several of the branches it appears that their contents in seasons of drought compare unfavourably with the raw sewage of some northern towns, and in all the degree of impurity is objectionably high. Having proved the existence of serious pollution, the authors endeavour to assign to the various sources of impurity the proportion for which each is responsible. At one time waste from works was thought to contribute more than was due to the influx of sewage, but at present there is reason to believe that the reverse is true, and that the manufacturer, though far from innocent, is not the greatest offender. Cotton mills and weaving sheds, bleach works, paper mills, dye and print works, woollen mills and tanneries, are all causes of pollution, the effluent in many instances being loaded with putrescent and putrescible organic matter sufficient to defile any stream of moderate dimensions. Contrary to vulgar belief, chemical works rarely contribute anything specially injurious; in fact, the commonest effluent—solution of calcium chloride—is innocuous, save for the increase in hardness caused by it.

Reviewing these facts, and considering means for the improvement of the present state of things, the authors lean to the opinion that it would be preferable, in the event of the enforcement of any restriction on the privilege of unlimited pollution, to frame the prohibition in general terms, and to fix a maximum amount of impurity as permissible in any effluent, rather than to attempt to regulate the practice of each industry. The book concludes with a description of the methods of analysis employed. These avowedly present little novelty, and are recorded in order to admit of comparison of the samples examined with those that may be analysed at any future time. The method for determining the "oxygen absorbed" differs in several respects from that commonly used, notably in operating in alkaline solution and at a high temperature, conditions which probably account for the high absorptions recorded. The *brochure* is accompanied by a map of the Irwell and its tributaries, and gives, in a compendious form, a mass of information, valuable alike to those concerned in the general question of river pollution and to those whose local interest is affected in this particular instance.

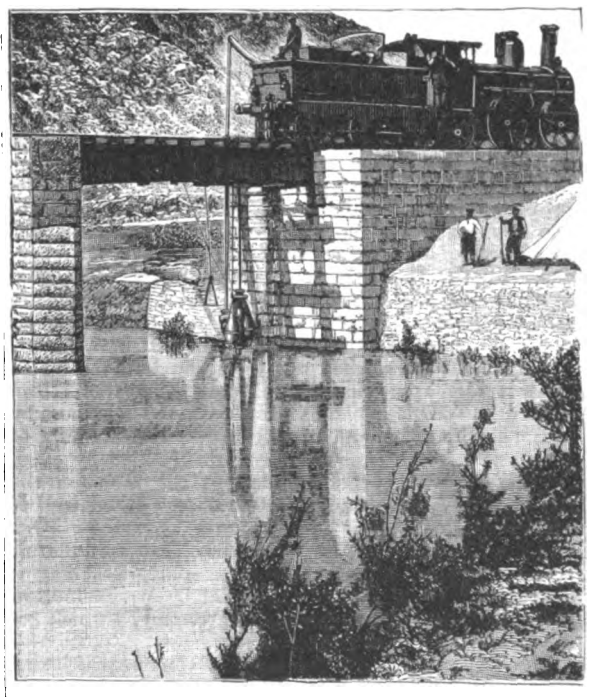
SKINNER'S IMPROVED BLOWER.

CONSTRUCTED BY THE PATENT PUMP AND BLOWER SYNDICATE, WATER LANE, LONDON, E.C.

GENERAL VIEW.

SECTIONAL ELEVATION.

SKINNER'S IMPROVED BLOWER.



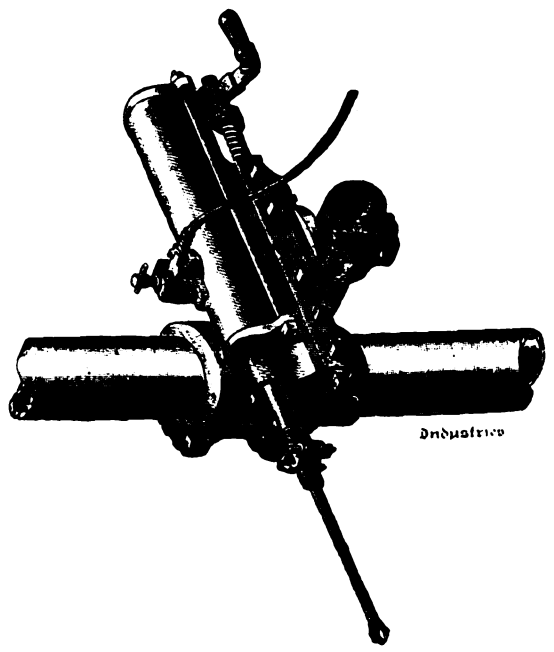
THE engravings given above show in elevation and section Skinner's improved blower, which consists of an outer cylinder or casing, closed by covers at each end. In the section the inlet passage is at the top, but the position of the inlet and outlet can be reversed if required. Inside the cylinder already mentioned, but eccentric to its axis, revolves an inner cylinder or drum D. To the periphery of this drum are attached the blades as shown. The outer ends of these blades are pivoted to segment plates. These segments are free to revolve round a fixed stud in the centre of the cylinder cover (this arrangement being shown dotted in the section), and the pressure on the blades is transmitted through the medium of the segments to the centre, thus reducing the friction to a minimum. The segments also perform the duty of keeping the ends of the blades in close contiguity, though without actual contact, with the inner circumference of the outer cylinder during the entire revolution, while they allow the blades to expand and increase in velocity as they approach the point of greatest eccentricity, and decrease again as they approach the point of the least eccentricity. Thus, when the inner cylinder is made to revolve in the direction of the arrow, the air contained in the cylinder between the points A and B, which is nearly half the contents of the cylinder, is carried forward and discharged three times in one revolution. The driving shaft is carried by a long hollow interior bearing extending from one of the end covers, and on this is also mounted the inner cylinder. The makers of the blower are the Patent Pump and Blower Syndicate, 7, Water Lane, London, E.C.

THE "SIMPLEX" GAS ENGINE.

IN our issue of August 2nd, 1889, we published in full, with illustrations, a paper read by Mr. Edward Delamare-Debouteville, of Rouen, before the Institution of Mechanical Engineers, on "Gas Engines, with a Description of the 'Simplex' Gas Engine." A series of trials with one of these engines, indicating 100 horse-power, has recently been made by Dr. M. A. Witz, of Lille, at the works of the makers, Messrs. Matter & Co., of Rouen. The engine under notice was of the single-cylinder type, having a cylinder 22·2in. diameter, with a stroke of 37·4in. and a speed of 100 revolutions per minute. It was fitted with automatic self-starting apparatus, and worked in conjunction with a "Dowson" gas plant, producing gas from English anthracite, and heated by ordinary coke. The steam used for injection purposes had to be obtained direct from a locomotive boiler, as a superheater, which is generally auxiliary to this plant, was not provided. The effective work of the engine was measured by means of a rope brake, which Messrs. Matter found to fulfil the requirements of a prolonged trial of twenty-four hours duration with one stop of half an hour for oiling purposes. The results, which were very satisfactory, showed the consumption of anthracite per horse-power per hour to be 516 grammes, consumption of coke per horse-power per hour 96 grammes, giving a total of combustible material per horse-power per hour of 612 grammes, which is equivalent to 1·24lb. of fuel per English horse-power per hour. These results are given in a well-illustrated book by Dr. M. A. Witz, in which are full particulars of the trials. The book also contains a comparative statement of gas engines and steam engines of equal power.

A NEW USE FOR THE PULSOMETER.

THE accompanying engraving represents a rather novel application of the pulsometer, for filling the tenders of locomotives with water. The arrangement is made by the Pulsometer Engineering Company, Limited, of 61 and 63, Queen Victoria Street, London, and, we are informed, has been adopted upon one of the Eastern railways, and appears likely to meet with considerable



success. The pulsometer itself is of the ordinary pattern, connected with the feed tanks and steam valves by flexible piping, and when not in use is carried on the tender. When about to be used it is simply lowered into a convenient stream or lake by suitable means. We are informed that the engineer on the railway mentioned has stated that the working of the pulsometer, as applied in the way shown, is extremely satisfactory.

NEW TYPE OF MARVIN ELECTRIC DRILL.

THE Edison General Electric Company, of New York, U.S.A., are now manufacturing and exploiting a drill making use of the principles of the "Marvin system of percussion tools." This drill, illustrated below, consists simply of a reciprocating iron bar impelled backward and forward by the action of two solenoids which are alternately thrown into action by pulsating electric currents.

This alternate action of the two coils is accomplished without the aid of commutators, collectors, or other moving parts on the drills which are involved in reciprocating motions in other machines, but is accomplished by the use of pulsating currents, positive impulses being

delivered to one coil and alternately negative impulses to the other. Since there are no moving parts in the drill except the reciprocating bar or plunger, there is no wear except in the guides. The heaviest parts of the drill are the tripod weights, which weigh about 100lb. each, and the two solenoid coils, which weigh about 55lb. each; and the largest piece, the cylindrical casing in which are enclosed the coils, is 38in. long by about 6in. in diameter. The total weight of drill and tripod is about 400lb.

The drill makes about 600 strokes per minute of a maximum length of about 4in., and will cut at the rate of 2in. per minute in the hardest granite with a 1½in. bit, and with a consumption of about 5 h.p.

Digitized by Google

The drills are run in parallel. The current, which is pulsating, is derived from a generator exactly similar to the standard Edison dynamo, except that it is supplied with pulsating current collectors, in addition to the regular commutator. The machine is thus self-exciting, and allows of continuous current apparatus being run on a separate circuit from it, at the same time that pulsating currents are delivered to the three wires leading to the drills. We are indebted to the *Electrical Engineer*, of New York, for our illustration.

NOTE ON THE LAW OF HYSTERESIS.*

By Chas. Steinmetz.

The magnetism of a magnetic circuit will vary periodically if subjected to a periodically varying magneto-motive force. The variations of the magnetisation, however, will not be simultaneous with the variations of the magnetic force, but show a certain lag, so that the curve of magnetisation, as a function of the magnetic force, forms a kind of loop, the well-known curve of hysteresis.

This phenomenon proves that in the production of the magnetic circuit by the conversion of electric energy into magnetic energy, and in the destruction of the magnetic flow by its reversion into electric energy, a certain amount of energy has been lost—that is, converted into heat.

The amount of energy converted into heat by hysteresis in a full magnetic cycle depends on the maximum magnetisation. It increases with increasing magnetisation, but faster than the magnetisation, so that, when for a magnetisation of B=3,000, the loss by hysteresis amounts to 736 ergs per c.c.; for four times as high a magnetisation, or B=12,000, the loss is 6,720, that is, more than nine times as high. On the other hand, the loss increases more slowly than the square of the magnetisation, because the square law would require a loss of 11,776 for B=12,000.

A great number of experimental researches on the loss of energy due to hysteresis, with different maximum magnetisations, have been made by Ewing; but the law is still unknown which gives the dependence of the hysteresis upon the magnetisation.

In trying to find at least a clue to this law, I subjected a very complete set of Ewing's observations, consisting of ten tests from an induction of 1,974 lines of induction per square centimetre, up to 15,560 lines per square centimetre, to an analytical treatment by the method of least squares, to ascertain whether the losses due to hysteresis are proportional at all to any power of the magnetisation, and which power this is.

The exponent of the power was so very nearly 1·6 that I can substitute 1·6 for it, and combine those observations of Ewing in the formula

$$H = \cdot 002\ B^{1\cdot 6},$$

where H is the loss due to hysteresis, in ergs per cubic centimetre per cycle, and B the maximum induction.

In Table I., in the first column, are given the values of the magnetic force F, in absolute units; in the second column is given the maximum induction B; in the third column the permeability; in the fourth column the hysteretic loss E, in ergs per cubic centimetre, as observed by Ewing; but in the fifth column the hysteretic loss calculated by the formula:

$$H = \cdot 002\ B^{1\cdot 6}.$$

The sixth column gives the differences of the observed and the calculated values; the seventh column gives these differences in percentages of E.

In the diagram given above these calculated values of hysteretic loss are shown in the curve; the black crosses show the values of hysteretic loss E observed by Ewing.

For comparison there are shown, in dotted lines, the curves of magnetic force F and of permeability as functions of the induction B.

It will be seen that the observed values of hysteretic loss are very near the calculated curve through the whole range of observation, and do not show any tendency to deviation, which justifies my considering this coincidence as something more than a mere accident, and, indeed, as an indication of a general law, although certainly this law might be more complicated than the formula.

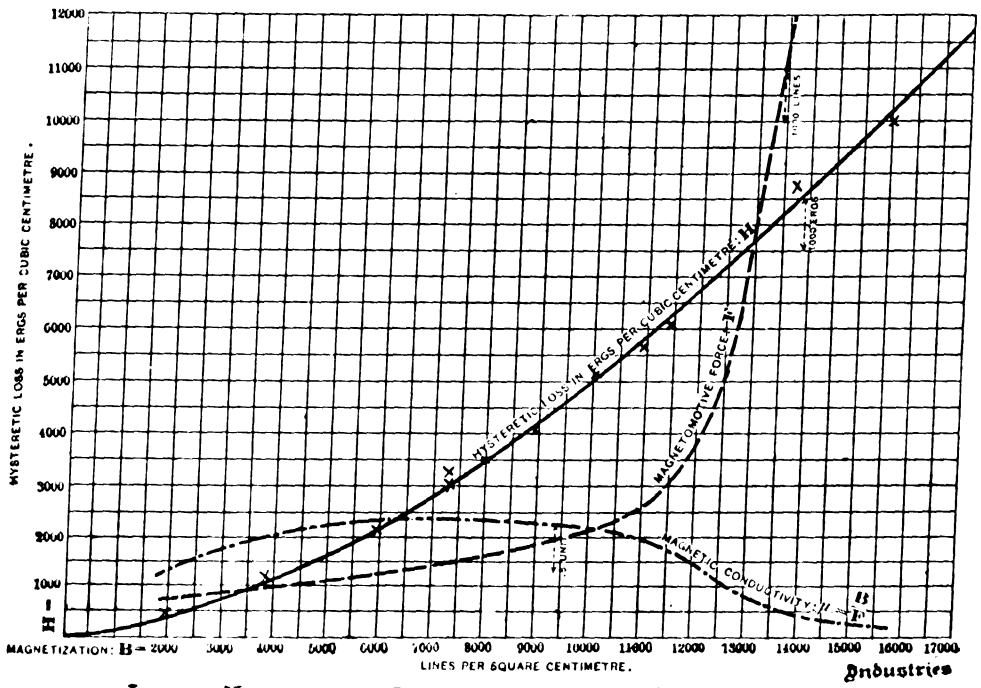
In Table II. are given the values of hysteretic loss, calculated by the formula:

$$H = \cdot 002\ B^{1\cdot 6}.$$

To one interesting fact I wish to draw attention: The hysteretic loss seems to be independent of the magneto-motive force F, and only dependent upon the magnetisation B; it therefore shows no special singularity at the point of the beginning of magnetic saturation, but increases in the last two observations in Table I., which, for an increase of B by 3,500, require an increase of F by 68, showing high saturation, according to the same rule as in the first eight observations, where B = 12,000 corresponds to F = 7. Therefore the "knee" of the magnetic curve is no singular point of the curve of hysteresis $H = \cdot 002\ B^{1\cdot 6}$, as the diagram shows.

TABLE I.

Comparison of Ewing's observed values of E, the energy consumed by hysteresis in soft iron, with the values calculated by the equation:



$$H = \cdot 002\ B^{1\cdot 6}.$$

F	B	μ	E	H	E - H	Diff. in Percentage.
1·50	1,974	1,330	410	375	35	8·5

10,000	5,020	30,000	29,280

ADULTERATIONS OF OLIVE OIL.

Adulterated olive oil has a very injurious effect when used in place of unsophisticated oil for oiling wool prior to dyeing. Not only is free acid highly prejudicial, since it strongly attacks the cards used in the subsequent spinning, but the addition of drying oils, resin, or mineral oils often causes very serious disturbance to the dyeing operations themselves. Cholesterin is often present in sophisticated oil, and it is known to be very obstructive to an even fixation of the colouring matter. These adulterations, of course, can be detected and estimated by the professional chemist, but Horvitz has recently given a summary of simple qualitative reactions which can be applied by those who have little knowledge of the detailed methods of oil analysis, or who have limited time at their disposal, which are as follows:—(1) A drying oil can be detected in olive oil by placing a clean copper wire in a mixture of 2 cubic centimetres of nitric acid and 5 cubic centimetres of the suspected oil. The mixture is then stirred with a glass rod, and after half an hour the copper rod will have a pink colour if a drying oil has been added. (2) A resinous or mineral oil is detected by first saponifying the oil—*i.e.*, by warming it with a solution of alcoholic potash, then evaporating off the alcohol and extracting the dried soap with petroleum ether. The ether will dissolve the resin or mineral oil if present, and after evaporating the ether, the residue is treated with bromide of tin (formed by adding dry bromine to tin filings), when a purple colour is produced. (3) Cholesterin can also be detected in the unsaponifiable portion by means of Schulze's colour reactions. Of these the most characteristic is to rub the residue with a few drops of strong sulphuric acid and then add chloroform, when a blood-red colour is produced, which changes through violet to blue on the subsequent addition of nitric acid.

THE RELATIVE STRENGTHS OF HIGH EXPLOSIVES.

Lieut. Willoughby Walke, of the U.S. Artillery, has recently communicated to the Journal of the American Chemical Society an important paper on the relative strengths of modern high explosives, which is interesting as illustrating the considerable variation in the comparative strengths, not only of different explosives of acknowledged value, but of the same explosive manufactured at different times and under slightly different conditions. It will be recollected that Mr. C. E. Munroe has already pointed out that the firing point of an explosive is also a very variable number. In his more recent experiments a thin copper cartridge was placed in a molten bath of tin or paraffin, the initial temperature noted by a thermometer, and the bath quickly heated until the explosive flashed off, when the temperature marked by the thermometer was again noted. The following table shows some of the results obtained:—

Description of Explosive.	Firing Point in deg. C.
Compressed military gun-cotton	186–201
Air-dried „ „	179–186
„ „ „	186–189
„ „ „	137–139
„ „ „	154–161
Gun-cotton dried at 65° C.	136–141

„ No. 2	165–177
„ No. 3	205–217

Lieut. Willoughby Walke, in his experiments, employed a Quinan pressure gauge for registering the pressures developed by the explosives in preference to other methods used by the older investigators, as even the *crusher* used by Berthelot gave only approximate results, as shown by MM. Sarau and Vieille. The instrument employed consisted of a heavy block of wood bolted to a cast-iron base, in which were four iron guides set around a 4in. circle. A steel plate is let into the iron block flush with

Digitized by Google

its upper surface, and a ring holds the guides in place at the top. The piston is a cylinder of tempered steel moving freely between the guides, and rests on a plug of lead which is to be compressed. The piston weighs 12¼lb., and the explosive is placed in a parabola-shaped cavity at its top. The shot was also made of tempered steel, 4in. diameter and 10in. long, and weighed 34⅓lb.

The instrument is worked in the following manner:—The lead plug is placed upon the steel plate, the piston placed gently upon it, and the shot next lowered upon it. The fuse is lighted, and the charge, in exploding, throws out the shot and compresses the lead plug. The accuracy of the test is based upon the assumption that the lead plugs are of uniform density and homogeneous in structure, and the author, by cutting his plugs from bars of pure lead manufactured from large masses of metal at a high temperature, believes that the error from want of these conditions is reduced to a minimum. The amount of compression is finally expressed in foot pounds by plotting the actual compressions measured by the Quinan gauge against the work actually done on the lead by known pressures. The author, however, did not plot out his results in this manner, but preferred simply to use the method for determining the relative strengths of the explosives examined, instead of calculating from the observed compressions the absolute pressures exerted. The following table gives a summary of the results obtained, the order of strength being given in numbers, nitro-glycerine having assigned to it the value of 100:—

Name of Explosive.	Compression of Cylinder in Inches.	Order of Strength.
Explosive gelatine (made by Vouge's process)	0·585	106·17
Hellhoffite	0·585	106·17
Nitro-glycerine (old)	0·551	100·00
Nobel's smokeless powder	0·509	92·38
Nitro-glycerine (fresh)	0·509	92·37
Explosive glycerine (made from above)	0·490	88·93
Gun-cotton (1889)	0·458	83·12
„ (1885)	0·458	83·12

Notes.

RAILWAYS IN COLOMBIA.

A Foreign Office report from Bogotá, United States of Colombia, states that no new railways were begun during the past year, and those already begun have not been extended. Several projects for the completion of the unfinished and at present useless railways in the country are being considered by Congress. It seems probable that a scheme proposed by an English company, the River Plate Trust Loan and Agency Company, Limited, of London, for completing the railway between Bogotá and the River Magdalena, at Tirardot, will be accepted. The other schemes are mostly proposed by American companies, and have met with a great and unexpected amount of opposition in both Houses of Congress, and as yet nothing definite can be said as to their chance of success.

ALIUM.

According to Mr. Rice, in the *Electrical Engineer*, of New York, Professor E. Thomson wants the metal got from clay to be called "alium." The Americans have always had considerable difficulty with the word "aluminium," owing to a determination to put an accent on the second syllable. They generally call it "aluminum" with the accent on the second or fourth syllable. "Alium" is certainly shorter and more euphonious, and leaves no opening for great variation in pronunciation, such as occur in many chemical words. Unfortunately aluminium is too well established to be easily changed; but when we remember that "eleemosynary" has telescoped into "alms," we may hope that "aluminium" will contract into "alium," and that "aluminum" will disappear from American literature.

BRITISH TRADE IN URUGUAY.

In the import trade of Uruguay Great Britain is almost without a competitor in the following articles:—Bagging, baize, carpets, cloth, coal, copper, cotton piece goods, iron bars, plates, roofing, hoops and pipes, lead and lead piping, rails, salt, soda, steel, sewing thread, tin and tinplates, waterproofs, and woollen mixtures. Though first in the following goods, we are closely approached by some of our rivals, and the hint deserves attention:—Arms and accoutrements (Belgium), canvas (United States and Germany), blankets and cotton (Germany and France), iron manufactures (Belgium, France, and Germany), and linen piece goods (Belgium, Germany, and France). The imports from England and Belgium show a general increase. The Merchandise Marks Act has had a beneficial effect in checking the practice of exporting from England as English goods, articles which are really of Continental origin.

MINING IN COLOMBIA.

Some activity has been lately displayed in work on the various mineral lodes which have been discovered from time to time in the Panama district, but as yet the results in bullion shipments have not been encouraging. A Foreign Office report states that the principal mine under development is the Cana, a mine situated in the Darien district, which gave great results in the old colonial period. The old workings have been explored and cleared out where necessary to future operations, new shafts sunk, and tunnels and drifts projected to reach the ore deposits. Pumping and hoisting machinery has been erected, and mills for dealing with the ore are now in course of erection. Some reserve is shown by the company's agent as to the positive character and value of the mine, but the geueral belief seems to be that there is mineral of paying quality, and in considerable quantity in the neighbourhood. At Las Cascadas, near the line of railway, work is in progress on a vein which shows free gold, and a part of which could be easily washed in the primitive way if water were obtainable in sufficient quantity, but the developments are not sufficiently advanced to justify opinion as to its value.

AMERICAN ELECTRICAL NOMENCLATURE.

The Americans have always been remarkable for a kind of conservatism which leads them to cling to old English words, or to primary meanings of them. A number of American expressions that we call slang are really old English. On the other hand, they have great facility in coining new words and phrases. The American electrician, however, has developed a new vice, in perversely assuming a wrong meaning. An English electrician, discussing a theoretical point with an American, often finds that there appears to be a complete lack of common ground. For instance, he will be told that two alternators are not "phased," or that the "leakage" in the transformers amounts to so many amperes. Magnetisation is frequently confused with induction in both countries, and the confusion of magnetomotive and magnetic force is perhaps inherent in the loose ideas which demand such a conception as "magnetic resistance." "Direct driving" in America means driving by a belt. Such loose expressions as "rate of speed" and "strength of current" are common, unfortunately, to both countries.

THE NEED OF A GOOD INSULATING MATERIAL.

There is a great want of an insulating material which will stand heat and damp, and can be worked or moulded. Porcelain is brittle, and warps a great deal in firing. It is also inaccurate in its dimensions. Moreover, it cannot be worked. Ebonite is too dear; it warps or softens under heat, and no cement will stick to it. Wood does not insulate well enough for high pressures, and warps easily. Celluloid warps, and is inflammable. Marble resembles loaf sugar in its character too closely to be durable. Slate is treacherous. One firm is bringing forward a material which consists of pure silica. This looks very promising. It comes out accurate to size, but must be moulded before firing, and cannot be worked. Portland cement is being worked with by one or two inventors. Shellac and mica make a very good material, but heat affects it. Various sulphur and earthy cements come out apparently well, but are inflammable. Spence's "metal" might be useful if the makers of it could be found. Vulcanised fibre, celluvert, and parchmentised fibres are exceedingly valuable for low-tension work, but some of them—we are not certain about all—break down at once under high pressures. Asbestos and shellac are combined to form tobacco pipes, and this material may be useful for electrical work, as there is so little shellac that it will stand considerable heat. An American production made of bone dust with some gum or resin compressed hydraulically was introduced about five years ago. It was expensive, but could be made to imitate almost any opaque stone, marble, or porcelain, and could be turned, screwed, or tapped. It seems to have disappeared.

THE LAW OF THE LOSS OF POWER IN IRON.

In another column we give an abstract of a paper by Mr. Steinmetz, showing that the energy absorbed per cubic centimetre of iron is $0{\cdot}002\ B^{1{\cdot}6}$, where B is the maximum induction. We do not know if Mr. Steinmetz has compared results calculated by this formula with those obtained from unannealed or hard iron and various qualities of soft iron. In any case it seems hardly possible that the result is more than accidental. Mr. Steinmetz's may be a useful empirical formula, but it is hardly likely to have any natural foundation, striking though the coincidence may be. It must be remembered that an empirical formula can be made to adapt itself to a great many curves by suitable choice of the coefficients, just as an enormous number of curves can be traced with fair accuracy with one French curve. Any one curious on these points may look up the hosts of curves of dynamo characteristics arrived at by empirical formulæ which obviously had no scientific foundation. Again, the candle-power of incandescent lamps is said to be proportional to the fifth or sixth power of the electrical power spent in the filament. Its life is supposed to be some other power of its efficiency, and so on. Mr. Steinmetz's formula may be useful, but most empirical formulæ do far more harm than good. The most interesting point, perhaps, is that there is no "knee" in the loss curve corresponding to the knee in the magnetic force and magnetisation curve. According to Ewing's theory, it is hardly to be expected there would be; in fact, it might almost follow that above the knee the loss of energy in reversal would lessen relatively to the magnetic force, though not necessarily relatively to the magnetisation.

TEXTILES IN SWITZERLAND.

An official report on the Swiss trade of 1889 states that the Swiss cotton industry has since the year 1876 been passing through a period of great depression, but the report for the past year is satisfactory, and indicates improvement. A gradually increasing demand both at home and abroad facilitated the sale of the large surplus stock of yarn, which had accumulated from previous overproduction, and this, coupled with a rising of prices, restored activity and confidence to the trade generally, though the high price of raw cotton prevented the year being a very remunerative one. The cotton industry is a great sufferer from the high protective duties in force in the neighbouring countries, and it is also sorely pressed by English competition. Raw cotton is imported chiefly from the United States and Egypt, and cotton goods from Great Britain. The greater portion of Swiss yarns go to Germany, Austria-Hungary, and Italy. The white cotton textures are largely purchased by the Alsatian printers, while the coloured and printed textures find the best markets in the East, especially in the Straits Settlements and India. The export to the Danube States of both white and coloured textures has assumed considerable importance during the last three years, but a greater demand for cheap English and Belgian goods is now said to be manifesting itself in those countries. Embroidery, which is generally included in the cotton industry, is carried on chiefly in the cantons of St. Gallen and Appenzell. Handwork has now been replaced by machinery for all except the finest embroidery, but in both branches of the trade the reports of last year are satisfactory. There was some improvement in the woollen industry during the year, especially in the manufacture of cloth. It has, however, lost much of its importance, and the linen industry is in a similar position.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

MACHINE TOOL ATTACHMENT.—*W. F. Pettigrew, London.*—The attachment is for the purpose of machining those parts of engines, such as the steam, exhaust, and other ports, valve faces, and other parts which are inaccessible in the ordinary way, and is designed to be attached to the sliding head of milling, drilling, and other like machines. The accompanying illustration shows a longitudinal section of an attachment constructed according to this invention. Bolted to a milling or drilling machine is one end of a cylindrical casing A so fixed that the nose of the machine

spindle can revolve freely within the casing. Running in a bearing formed in the outer end of A is a spindle B, the opposite end being screwed into the nose of the machine spindle. On the outer end of B is a pinion C, which gears with a bevel gear wheel fixed to a hollow spindle D running in bearings in the end of A as shown, and which spindle is formed to carry milling cutters, taps, drills, slot drills, rymers, rose bits, &c. Claims: (1) In a machine tool attachment for the purposes above specified, a hollow spindle forming a tool holder and means for rotating the said spindle upon or about its axis; (2) the combination of a casting and spindle, the said spindle fitted to rotate in the spindle of the machine to which the machine tool attachment is fixed; (3) the improved machine tool attachment consisting of the parts constructed and combined as described and illustrated, and operating in conjunction with a machine as stated, and for the purpose above specified.—No. 19866. December 10th, 1889. 8*d.*

STEAM TRAPS.—*J. Butterworth, Micklehurst, Mossley, near Manchester.*—The inventor constructs a steam trap in the following manner:—A vessel or chamber of any convenient shape, called the water chamber, is employed, into which the water of condensation is allowed to drain. This water chamber is fitted near its lower end with a double-beat or equilibrium valve mounted on a spindle carrying at its upper end a ball float. A branch pipe on the valve casing passes through the side of the water chamber, so supporting the valve casing, and is secured on the outside by a T piece to the discharge pipe leading to the drain. The other end of this T connection leads up to the air valve outlet situated in the cover of the water chamber, and which is surrounded with a circular beading forming an open-topped cavity. Into this a domed cover may be inserted, to which is connected the last-mentioned pipe, so allowing any drip or foul gas to be led away with the water of condensation. The action of the apparatus is as follows:—As soon as sufficient water of condensation accumulates in the water chamber to reach the ball float, the same becomes sufficiently buoyant to raise the equilibrium valve, so opening the two escape orifices and allowing the water to escape. Claims: (1) The improved arrangement and construction of steam traps substantially as described; (2) in a steam trap or discharge pipe of any analogous apparatus the employment of an improved double-beat equilibrium valve and float, mounted and operated substantially as described.—No. 1465. January 28th, 1890. 6*d.*

PISTONS.—*W. Jowett, Mellor, near Marple Bridge, & G. Spencer, Hyde, both in Cheshire.*—The object of the present invention is to effect a close fit between the piston and its cylinder. In the accompanying illustration Fig. 1 is a vertical section, and Fig. 2 a plan, taken without the junk ring, of a piston, constructed with these improvements, for a double-acting engine. A is the piston block, B the piston rod, C the junk ring, D D^1 are the piston rings, E E^1 are the inclined faces of the ends of the piston rings, F F^1 are the cylindrical holes bored radially in the piston block for the reception of the rams G G^1, H H^1 are the wedge-shaped heads of the rams fitting between the inclined faces E E^1 of the piston rings, I I^1 are packing rings on the rams, J J^1 are openings from the faces of the piston and communicating respectively with the radial cylindrical holes F F^1 in the rear of the rams G G^1, K K^1 are holes bored in the piston block radially thereto and each diametrically opposite to the one of the holes F F^1, L L are spiral springs abutting against the bottoms of the holes K K^1 and pressing upon the inner faces of the piston rings, and X Y are respectively the opposite faces of the piston. The action of the apparatus is as follows:—Supposing fluid pressure is being exerted on the face X, the fluid will enter the opening J and

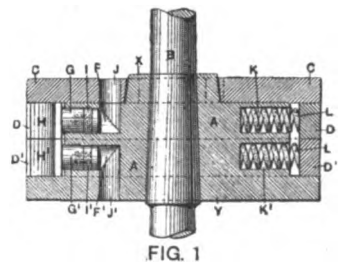

FIG. 1

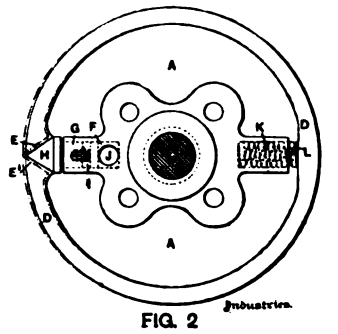

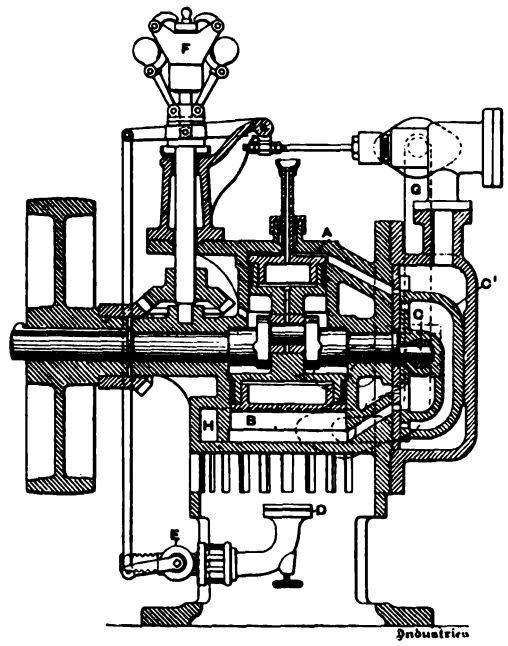

FIG. 2

exert its pressure on the base of the ram G, forcing its wedge-shaped head between the inclined faces of the ends of the piston ring, thus expanding the piston ring; at the same time the spiral spring L is pressing the diametrically opposite portion of the ring into close contact with the walls of the cylinder. It is thus claimed that the pressure of the piston ring against the walls of the cylinder is in direct proportion to the fluid pressure on the piston. Claims: (1) A piston having its ring or rings expanded by the fluid pressure acting upon the face of the piston, constructed and arranged substantially as hereinbefore described and as illustrated by the accompanying illustrations; (2) in a piston to be acted upon by fluid pressure, the combination and arrangement of a divided ring having its ends formed to inclined faces, a radial ram having a wedge-shaped head working between the inclined faces of the ends of the piston ring and a radial spiral spring acting upon the inner face of the piston ring diametrically opposite to the ram.—No. 16141. October 11th, 1890. 6*d.*

COMPRESSED AIR MOTORS.—*J. C. Mewburn, London.* (*D. R. Proell & O. L. Kummer & Co., all of Dresden, Germany*).—The principal object of this invention is to prevent undue reduction of temperature in the cylinder when using air expansively. The accompanying illustration is a sectional elevation of a compound

motor constructed according to this invention. The pistons of the high and low pressure cylinders A and B are connected together by a common piston rod and connected to the driving shaft by means of a sliding block in the usual manner. An eccentric crank C on the main shaft actuates the slide valve C^1 in a similar manner, the slide being constructed substantially as shown and represented in the illustration in a position to allow the exhaust from B to escape. The gas jet D for heating the bottom of the low-pressure cylinder B is governed by a tap E actuated by means of a connecting rod attached to one end of a lever pivoted to the sliding collar of an ordinary governor F at its centre, and to a bracket, as shown, at its other end. This latter end of the lever carries a small arm, by means of which the throttle valve in the supply pipe G is actuated. Around the low-pressure cylinder an annular space H is formed, through which the compressed air may be caused to pass before entering the high-pressure cylinder, so absorbing heat from the gas jet D. Four claims are made.—No. 132. January 3rd, 1890. 8*d.*

DIES FOR PRESSES.—*J. H. Tozer & W. Tozer, both of London.*—The invention has reference to the manufacture of hollow articles from blanks of metal, and relates more particularly to the formation of boxes of railway or other buffers. For this purpose a sheet of metal is taken of a thickness greater than that of the walls of the buffer case to be produced. This plate is suitably heated, and is then subjected to the pressure and action of a male and female die constructed in the ordinary manner—that is, the female die being formed internally of a shape similar to that of the outside of the case to be pressed, and the male die being formed externally of a shape similar to the inside of the case to be pressed. The male or movable die has formed around it, and enclosing it, a suitable movable casing, the lower end of which is of an internal diameter equal to that of the size of the opening of the female die. This casing is, before the male die is operated, forced down upon the plate to be operated upon, so holding it, but allowing the male die to act upon that part over the female die into which it is forced by the former. The outer portion of the plate thus remains unaffected by the pressing operation, and constitutes the flange of the finished case, which flange may be afterwards made thinner and cut to the desired size and shape by the action of a second pair of dies of the usual construction. Four claims are made.—No. 1294. January 24th, 1890. 8*d.*

LUBRICATORS.—*K. A. W. Jakobson, Christiania, & T. Röstad Moss, Norway.*—In the accompanying illustrations Fig. 1 is a vertical section and Fig. 2 a plan of a lubricator constructed according to this invention. The frame A has formed in it a cylinder B of variable diameter, in which works a plunger and rod C and slide C^1, operated by means of a rod D, carrying a

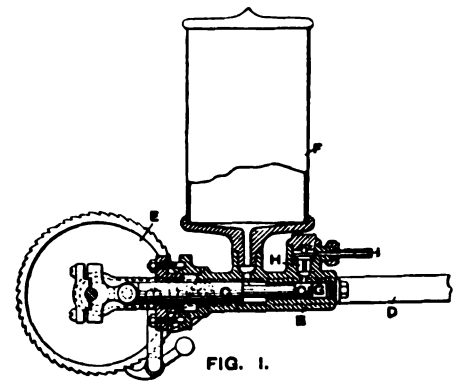

FIG. 1.

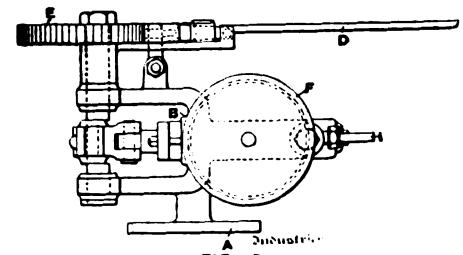

FIG. 2.

pawl. The latter actuates the ratchet wheel E, the shaft of which has formed on it a crank connected to the rod C. Connected to the cylinder B is the oil reservoir F. The plunger and rod C and slide C^1 are so arranged that the plunger C closes the passage leading from the oil reservoir immediately before the slide C^1 opens the passage G leading through the non-return valve H and tube I to the parts to be lubricated; in consequence of the unequal diameter of the cylinder B, a compression is caused of the oil contained in the cylinder, and the oil being subjected to the pressure of the plunger is compressed and so forced to the required places. Claims: The lubricator as described in two claims.—No. 14537. September 15th, 1890. 6*d.*

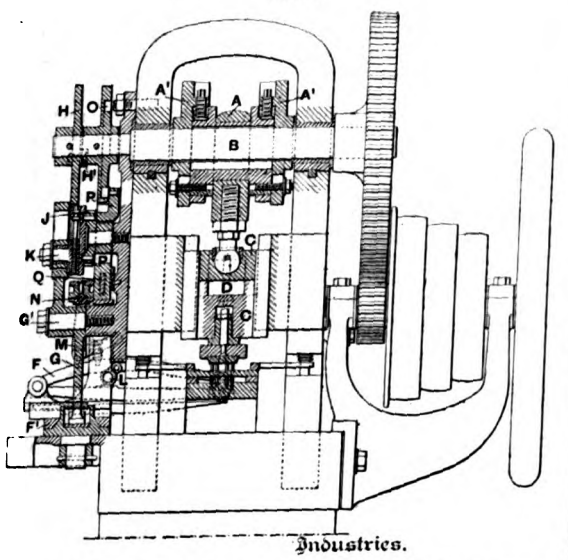
CARDING ENGINES.—*T. S. Whitworth, Cheetham, Manchester.*—This invention relates to what are known as revolving flat carding engines, and consists principally of improvements upon a prior patent, No. 3556 of 1884. Secured to the bend of the carding engine is a circular surface having the same axis as the main cylinder of the carding engine. Upon this circular surface, and capable of being turned thereon, is mounted a disc, a portion of the surface of which is formed as a spiral curve, which curve supports a number of brackets, each of which may move longitudinally in suitable guides formed in the "bend" of the carding engine. The outer ends of these brackets support the "revolving flats" when such "flats" are carding. In order to form the outer ends of the brackets of a curve concentric with the axis of the main cylinder a "grinding roller" or milling tool is secured to the main cylinder, and is so mounted as to be capable of being adjusted nearer to or farther from the axis of the main cylinder. In order to readily attach the grinding roller or milling tool to the main cylinder, upon the arms of the main cylinder are formed facings to which the brackets for supporting the grinding roller may be fixed. After the outer ends of the brackets have been formed of a curve concentric with the axis of the main cylinder by the grinding roller, the latter and the parts carrying it are removed. When it is desired the flats may be adjusted nearer to or farther from the axis of the main cylinder by the disc being turned upon the circular surface by which it is carried. Four claims are made, embracing the arrangement as described, with modifications.—No. 1260. January 24th, 1890. 8*d.*

Digitized by Google

GUIDE EYES FOR SPINNING FRAMES.—*J. Wood, Allerton, near Bradford.*—The invention relates to an improved guide eye for the top boards of spinning frames. A guide eye constructed according to this invention is formed of a suitable metal plate provided at its upper side and around the hole in its centre with a flange, which is let into the top board, the plate being secured by screws in the ordinary manner. The lower inside edge of the eye is faced with brass, this brass being in the form of a bush let into the eye and provided with a smooth surface for the yarn to bear against. The usual angular slot leading from the eye to the edge of the top board is cut in the usual manner. Claims: The improved construction of guide eyes substantially as described.—No. 17085. October 25th, 1890. *6d.*

PRESSES.—*R. Picard, Paris, France.*—The apparatus here described is for the purpose of simultaneously cutting or shearing and embossing metals. In the accompanying illustrations Fig. 1 is a vertical longitudinal section, Fig. 2 a front elevation, and Fig. 3 a transverse section of such an apparatus. The eccentric A on the main driving shaft B is connected by means of a ball joint to the slide C carrying the tool. This slide is formed of two parts, coupled together by means of the key D, the withdrawal of which instantly arrests the movement of the tool. The eccentric A is made adjustable by means of two cheeks A^1 and set screws, as shown, so that the travel of the slide C can be varied. The strip to be cut is fed over the table guide E, which is adjustable in every direction by means of two grippers F, one of which is mounted at each side of the machine. The horizontal movement of the slide F^1 carrying the grippers F is effected by means of a rocking lever G pivoted at G^1, whose movement can be regulated as desired, and which is operated by means of a disc H keyed to B, and provided by two rollers H^1 engaging successively in a groove in a disc I, the rotation of which is transmitted by means of toothed gearing to the toothed wheel J carrying the actuating pin K. The grippers are closed by means of springs placed beneath their lower jaws, the opening being effected by means of a cam L working between the two jaws, and itself operated by the levers M, which are connected to a cross-bar N so as to work in unison. The actuating power is derived from a groove in a disc O secured to B, in which works a roller mounted upon a slide P coupled to the cross-bar N by means of a key Q, which can be displaced at will by a hand lever R. Three claims are made.—No. 6030. April 21st, 1890. *11d.*

FIG. 1



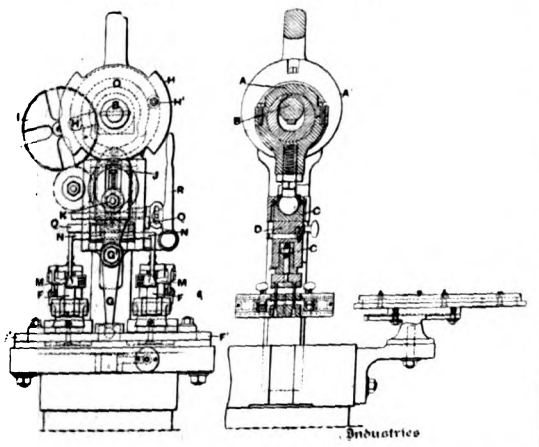


FIG. 2. FIG. 3.

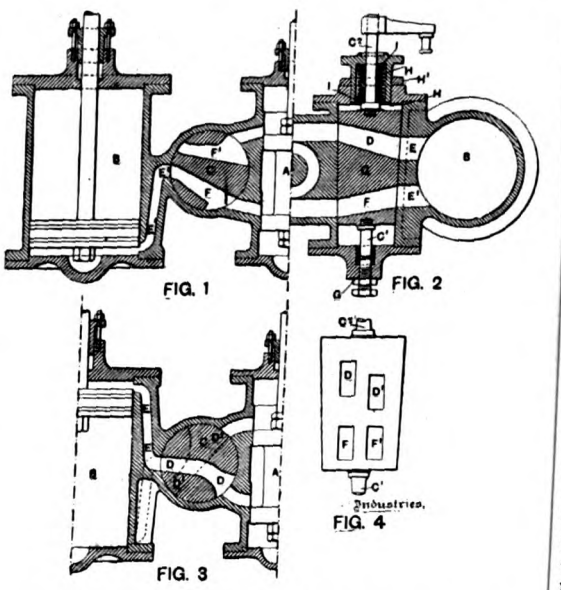
REDUCTION OF METALLIC ORES.—*J. T. King, Liverpool.* (*C. Adams, Pittsburgh, Pennsylvania, U.S.A.*)—The invention relates to the reduction of ores by means of a current of heated gas, such as carbonic oxide, and consists essentially in subjecting the ores to the action of a horizontal stream or streams of heated reducing gases moving in a continuous zig-zag path. For the above purpose the inventor constructs chambers or receptacles of a convenient shape and size with gas inlets and outlets, and with diaphragms, partitions, or other dividing pieces, so disposed that the heated reducing gases are caused to travel through the ore placed in such chambers in a horizontal path. The inventor also constructs the reducing apparatus with a reservoir for receiving and containing the reduced ore, and combines the said apparatus with an open-hearth steel-melting furnace when iron ores are being reduced. Nine claims are made, embracing the construction of apparatus embracing the general improvements as described.—No. 1443. January 28th, 1890. *1s. 1d.*

MACHINE BELT FASTENERS.—*W. Thompson, Crompton Fold, Shaw, near Oldham, Lancashire.*—For the purpose of this invention the inventor casts in malleable iron a light plate of a width somewhat less than that of the strap to be joined, and having a row of three or more holes at each end, and at the back of the plate a projecting socket cast round each hole (which may be slotted as desired), the depth of the sockets being about equal to the thickness of the belt. The ends of the strap are cut in the form of a "butt" joint, and have holes punched in them, which, when the ends are brought together, coincide with the sockets in the metal plate, which latter are pressed into the holes in the belt. The whole is then made fast by means of corresponding rivets, preferably cast with small teeth at the back of the head, these rivets being pressed in from the back of the leather and riveted on the face of the plate. The rivets may be either cast separately or cast in groups on a single plate, which answers for the heads of all the rivets. Claims: (1) That these hollow tubes or sockets take all stress off the rivets and prevent the rivets from springing or bending during the time of fastening; (2) that these hollow slotted sockets expand during the time of insertion, thereby making a firm junction.—No. 12265. August 6th, 1890. *6d.*

VALVES FOR STEAM STEERING GEAR.—*J. Shenton, Oldham, Lancashire.*—The object of this invention is to provide partially rotating steam valves which are balanced, more sensitive, prevent wire drawing, and the wear of which can be compensated for. In the accompanying illustration Figs. 1 and 3 are sectional plans, Fig. 2 a sectional end view, and Fig. 4 the valve plug of a partially rotating valve constructed according to this invention and applied to steam steering gear. Between the ordinary regulating valve A and the cylinders B is employed a conical partially rotating valve C. In the valves C (Fig. 4) are formed two ports D D^1 on their upper ends, which cross each other (Fig. 3). These ports are so arranged that by partially rotating C and moving the regulating valve A connection can be made between the front end of the cylinder through port E and the exhaust or steam supply. Two other ports F F^1 are made in C which similarly admit and exhaust steam from the back end of the cylinder through port E^1. To compensate for wear in C its lower shank C^1 rests upon screwed plug G fitted into the valve casing and fixed by means of lock-nuts. Thus by lowering G the valve C can be allowed to drop as desired. The stuffing-box of the upper shank C^2 of C is made packingless as follows:—A cylindrical casing H is screwed into the valve casing and fixed by lock-nut H^1. Passing through the outer end of this casing is the shank C^2 of C. Around C^2 and inside H are two flanged bushes I forced respectively against the outer end of H and the top of C by a suitable spiral spring. The inventor also describes a method of applying the above-described arrangement to stationary engines. Three claims are made, embracing the construction and use of partially rotating valves as described, with modifications.—No. 18963. November 26th, 1889. *8d.*

FIG. 1 FIG. 2



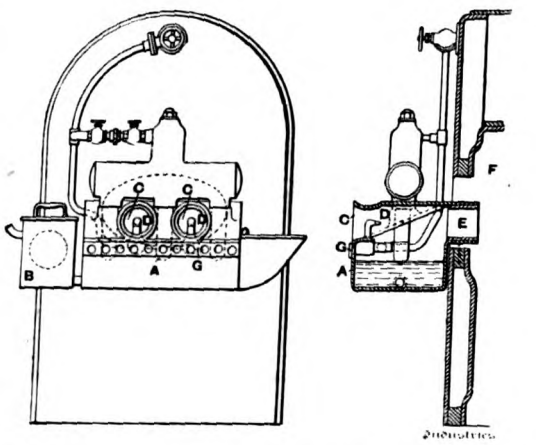


FIG. 3 FIG. 4

THRUST BLOCKS.—*H. Lamb, Erith, Kent.*—The thrust block constructed according to the invention consists of a ring formed of two halves and clamped in the usual manner to the shaft whose longitudinal movement it is desired to prevent. Formed in this ring, between its inner and outer peripheries, are suitable openings, in which are fixed pins, placed radially to the axis of the ring, and carrying upon them conical-shaped rollers of hard steel, with their larger end outwards, the peripheries of which project beyond each side of the ring. One side of this plate, when fully fitted with the conical rollers as described, is placed against a block on the shaft or against the block of the screw itself (when applied to propeller shafts). On the opposite side of the ring carrying the conical rollers is fixed to the shaft a solid metal plate of a suitable size and shape to sustain the thrust pressure of the shaft on the bearing. In this solid plate, and also in the bearing block on the shaft, are formed grooves corresponding with the shape of the rollers in the ring fixed to the shaft, such grooves being deep enough to admit the rollers just such a distance on either side that they can work freely without any portion of the ring touching either the block or the plate. Claims: (1) The application of rollers in connection with thrust blocks or bearings for the shafts of marine and other machinery; (2) the construction and use of a suitable frame to contain these rollers, as described.—No. 1991. February 6th, 1890. *6d.*

OIL BURNERS FOR STEAM BOILERS.—*G. S. Grimston, London.*—The invention relates to oil burners to be used for heating steam boiler furnaces. In the accompanying illustrations Fig. 1 is a front view and Fig. 2 a vertical section of a steam boiler having an oil burner fixed thereto, constructed according to this invention. The oil basin A is supplied with oil to a constant level from a cistern B fed by a ball-cock. Above the oil level in A are formed conoidal air inlets C. In line with each of these inlets is a central nozzle for a steam jet D, acting as an injector for drawing in air, and the vapour on the surface of the oil being kindled directs the flame through passage E into the flue F of the boiler. Besides the air entering at C additional air enters by apertures below, regulated by a valve G. The boiler H mounted over the flame chamber is for the purpose of supplying the nozzle D with steam until steam is generated in the main boiler. The inventor also describes a forge heated by a similarly constructed burner. Claims: An oil burner for furnaces, consisting of a basin supplied with oil, above the basin on the one side an air inlet, with steam injector jet, and on the other side a flame passage, arranged and operating substantially as described.—No. 952. January 18th, 1890. *8d.*

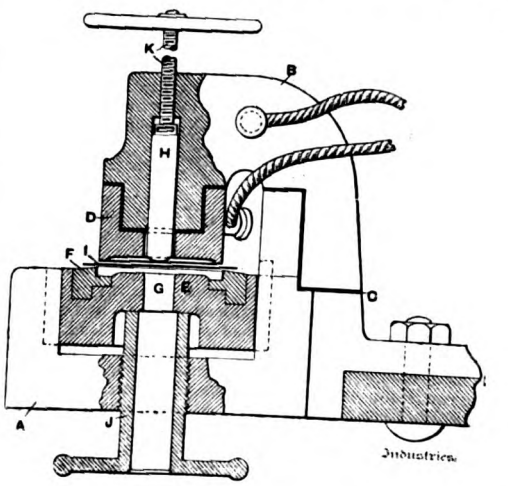

FIG 1. FIG. 2.

ELECTRICITY.

ARC LAMPS.—*A. Apps, London.*—The object of the present invention is to improve the colour and increase the intensity and steadiness of electric arc lights with the least expenditure of electric energy. To effect this the arc is fed with hydrocarbon vapour by causing the vapour to pass up through the lower carbon from a suitable reservoir containing the hydrocarbon situated at or near the bottom. The upper carbon is of the usual kind. The lower carbon is fitted with a tube or lining containing a very small hole, through which the oil from the reservoir first ascends by capillary attraction, and, subsequently becoming vaporised, passes into the arc, playing between the electrodes The hole in the carbon is lined with a suitable refractory insulating material, such as kaolin, lime, or plaster of Paris. Claims: (1) A tubular carbon for electric arc lamps containing a lining of refractory material as described; (2) a carbon for electric arc lighting having an axial passage provided with a lining for supplying liquid by capillary attraction as described; (3) the combination of an electric lamp carbon having a small central tube of refractory material with a source of hydrocarbon supplied at the inlet end of the tube as described; (4) the combination of a tubular carbon with a plastic refractory insulating material and a core adapted to form a capillary tube within said plastic material when dry, substantially as described.—No. 8427. May 31st, 1890. *6d.*

PRESSES.—*M. W. Dewey, Syracuse, New York State, U.S.A.*—The inventor here draws cartridge cases out of sheet metal in the ordinary manner, electricity being, however, utilised to heat the sheet metal to make it more pliable. The accompanying illustration is a side elevation partly in section of a press for this purpose. The part A of the framework is insulated from the arm B at C as shown. Fixed on but insulated from B is the annular stationary cutting die D. Working in A *is a disc E*, having on its upper surface the disc-cutting ring F, and having formed in its centre a hole G, through which the metal is forced by means of a cylindrical plunger H. The arm B is connected to one pole of the electric generator and the die D to the other. The operation is as follows:—A sheet of metal I having been placed between D and E, the latter, together with F, is raised

Digitized by Google

by means of a screw J. A sheet metal disc is so cut, and the electric circuit is completed from H through the metal disc to D. The disc so becomes heated, and the plunger is then operated by screw K and forces the disc through E, thereby forming a cup or case, which is afterwards finished in the usual manner. Six claims are made.—No. 16416. October 15th, 1890. 8*d*.

ELECTRICAL CONDUCTORS.—*L. W. Tracy & J. E. Granniss, both of New York, U.S.A.*—The invention relates principally to the covering of insulated electrical conductors with lead sheaths and also to the formation of lead piping. In the accompanying illustrations Fig. 1 is a vertical section and Fig. 2 a plan of an apparatus for effecting the object of this invention, and Fig. 3 is a vertical section of a modified form of such an apparatus. Referring to Figs. 1 and 2, A is the head of the press, B the lead

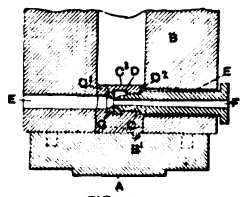

FIG. 1.

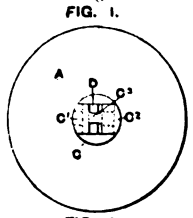

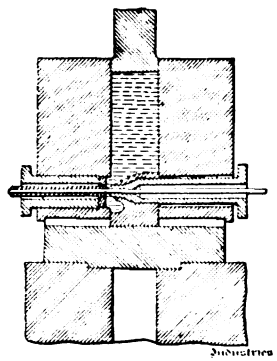

FIG. 2.

FIG. 3.

cylinder, and C the block mounted upon A and located in the lower end of B. The block C has two vertical portions C^1 C^2 with an intervening space D which constitutes the lead pipe forming chamber. Each portion C^1 C^2 of the block is apertured as shown, and openings E are formed in the walls of B coinciding with those in C. The core bar F is inserted through the opening in B and is screwed into the position C^2 of C as shown. The die G is seated in the opposite portion C^1 of C as shown. It will thus be seen that as the lead is pressed down B it will be forced to escape through the annular outlet formed by the end of F and the die G, and as the insulated wire is caused to pass through the die the lead forms a covering around it. In Fig. 3 the block C is slightly modified in form. It will be obvious from the above that if no insulated wire is passed through the apparatus the lead will issue in the form of a tube. Seven claims are made.—No. 9937. June 26th, 1890. 8*d*.

MAGNETIC SEPARATORS.—*F. Christy, Chelmsford, & J. H. Carter, London.*—The object of the present invention is the separation of iron from bones and other substances as the latter are being fed into a disintegrator or other grinding machine. For this purpose a cylinder of iron is employed, which is studded with a large number of electromagnets set radially, and the outer ends being of alternate polarity. The magnets are so wound and commutated that during one-half of a revolution they are active and the other half passive. The material to be treated in the grinding machine is fed on to the top of this cylinder, and carried forward as the cylinder revolves, the non-magnetic material falling off at the side and so into the grinding machine, the iron being carried half round and dropped into a separate receptacle. The feeder for supplying the material to the cylinder is continually shaken to cause the iron by gravity to sink below the bones, and so come in direct contact with the poles of the magnets in the cylinder. When dealing with material having about the same weight and density as iron, this mechanical separation is assisted by placing powerful electromagnets on the underside of the feeder. Claims: (1) In a magnetic separator the combination of a revolving electromagnetic cylinder and shaking feed shoot substantially as described; (2) in a magnetic separator the combination of a magnetic cylinder, shaking feed shoot, and powerful magnets beneath the shoot as described; (3) the combination of a disintegrator and magnetic cylinder as described, the magnetic cylinder serving the double purpose of a magnetic separator and an automatic feeder to the grinding machine; (4) the magnetic cylinder, with studs, standing out radially from a central core in lines parallel with its axis, and with two or more studs in each line, each carrying a magnetising coil, and with coils so wound that the pole pieces in each line and in alternate lines are of alternate polarity as described; (5) the construction of a magnetic cylinder substantially as described.—No. 530. January 11th, 1890. 8*d*.

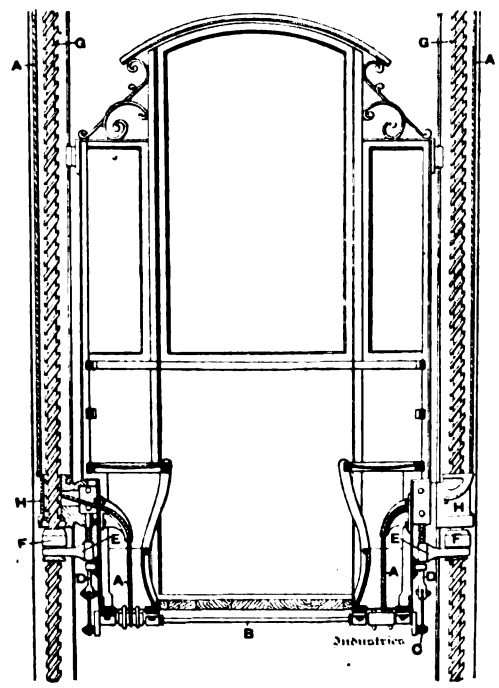
CHEMISTRY.

PRESERVING FLAX, HEMP, &c.—*E. T. Truman, London.*—For the purpose of preserving hemp, flax, jute, cotton, gutta percha, indiarubber, or wood from decay, the inventor employs any of the oxides of manganese, lead, barium, and copper, and more particularly the peroxides of manganese, lead, and black oxide of copper, which are known to have the property of decomposing ozone in practically unlimited quantities, and by its decomposition converting it into pure oxygen. The reason that these oxides tend to preserve hemp, flax, and other substances is, the inventor believes, that ozone is the active agent in inducing gradual decay, and therefore its decomposition by the said oxides on coming in contact therewith, and its consequent conversion into pure oxygen, prevents decay or oxidation of the materials to which such oxides are applied. In employing these oxides for the preservation of hemp, flax, gutta percha, indiarubber, &c., they may be mixed with ozokerite, tar, or other such substances necessary or desirable for their utilisation or application. Claims: The treatment of hemp, flax, jute, cotton, and other substances, in order to preserve the same, with one or more of the following oxides substantially as described:—Black oxide or peroxide of manganese, black oxide of copper, peroxide of lead, and peroxide of barium.—No. 19773. December 9th, 1889. 4*d*.

RECOVERY OF ZINC FROM GALVANISED IRON.—*H. Grimshaw, Clayton, Manchester.*—For effecting the above the inventor dissolves the zinc from the surface of the iron or steel by means of a solution of the chloride, of the nitrate, or of the sulphate of zinc, or of a mixture of these solutions, by the aid of heat and with or without the addition of sulphuric, hydrochloric, or nitric acid. The process may be originated by employing a diluted solution of hydrochloric, nitric, or sulphuric acid, when the acid of the bath will combine with the zinc to form the salt in solution, or the salt may be dissolved in water to form the bath. In either case, in continuing the process, fresh portions of acid and fresh quantities of the galvanised metal are added from time to time as may be required, and the saturated liquid may be drawn off and the cleansed metal be removed as they respectively accumulate, so that the process may be continuous. If the heat developed by the reaction is insufficient to maintain the bath at a temperature of about 200° F. artificial heat may be applied. Claims: The above-described process for the recovery of zinc from galvanised iron or steel, which process consists in dissolving the zinc in a hot solution of the chloride, sulphate, or nitrate of zinc, either neutral or acidulated with hydrochloric, sulphuric, or nitric acid, substantially as set forth.—No. 1053. January 21st, 1890. 4*d*.

MANUFACTURE OF AZOAMINES.—*J. Imray, London.* (*La Société Anonyme des Matières Colorantes et Produits Chemiques de St. Denis, A. F. Poirrier, & D. A. Rosenstiehl, all of Paris, France.*)—This invention relates to the manufacture of azoamines by the reduction of the azo colouring matters derived from nitramines. This invention is based upon the fact that the following phases may be noted during the above process:—(1) The first product of the reaction is a colouring matter derived from azoxyamine. Two molecules of nitrated azo matter combine into one, losing three atoms of oxygen out of the four that are united with the nitrogen in the compound; (2) as the reducing agent continues to act, the last atom of oxygen is removed in its turn, and there are formed azo matters derived from azoamines; (3) in a third phase, the last-named substances are converted into free azoamines and into an amido derivative, the nature of which need not be considered here. The first phase above-mentioned already forms the subject matter of a prior patent. The process which forms the subject of the present invention is based on the reactions mentioned under the second and third heads. Example: Paranitraniline is diazotised and coupled in the well-known manner with bisulphonaphthol. 100 kilos. of the azo colouring matter thus obtained are dissolved in 1,000 litres of water rendered alkaline by the addition of 100 litres of caustic soda solution of 40° Bé. The temperature is raised to 50° C. to facilitate solution, and then 80 kilos. of glucose of 75 per cent. are introduced. When the whole is well mixed it is heated to ebullition, the violet colour of the liquor gradually changing to a brown. By cooling the para-azoaniline is separated in the form of crystalline needles; it is collected and washed with water, and purified by being redissolved in hydrochloric acid, filtered and neutralised by soda. The azoaniline is then precipitated, collected, washed, and dried. Claims: The manufacture of azoamines by the reduction of the azo colouring matters obtained from nitramines, as described.—No. 1579. January 29th, 1890. 6*d*.

PRODUCTION OF ALUMINIUM.—*H. White, Cheshunt, Hertford, executrix of W. White.*—The inventor manufactures aluminium from aluminium fluoride prepared artificially by evaporating to dryness a solution of alumina or aluminium hydrate in hydrochloric acid. The aluminium fluoride is heated with sodium or potassium, or both; aluminium is liberated and fluoride of sodium (or of potassium, or both) is formed. An excess of aluminium fluoride is preferably used, as it helps, by combining with the fluoride of sodium (or of potassium, or both), to form a suitable flux for the metal. This flux, when treated with sulphuric acid, gives up its fluorine as hydrofluoric acid, which is used for dissolving alumina or alumina hydrate in preparing fresh supplies of aluminium fluoride. Claims: (1) The use of the fluoride of aluminium obtained by evaporating to dryness a solution of alumina or aluminium hydrate in hydrofluoric acid; (2) the production of aluminium substantially in the manner described.—No. 859. January 16th, 1890. 4*d*.



COLOURING MATTERS.—*O. Imray, London.* (*The Farbwerke Vormals, Meister Lucius & Brüning, Hoechst-am-Main, Germany.*)—By heating a mixture of aniline, hydrochlorate of aniline, and of amidoazobenzol, there is produced an "induline," from which the inventors have isolated (1) an induline, $C_{24}H_{18}N_4$ (HCl), the base of which forms with organic acids stable salts soluble in water; (2) an induline soluble in spirit, the base of which does not form salts with organic acids. By heating the induline, $C_{24}H_{18}N_4HCl$, with aromatic meta- and para-diamines there are produced colouring matters of the induline series soluble in water, as described in Letters Patent No. 16325 of 1888. Valuable colouring matters of the induline series soluble in water are also produced from the induline soluble in spirit (2) on its being heated with aromatic diamines, notably with paraphenylenediamine. Example:—100 parts by weight of the induline soluble in alcohol, 150 parts by weight of paraphenylenediamine, 30 parts by weight of hydrochlorate of paraphenylenediamine are heated to 180° C. in an enamelled vessel furnished with a stirrer, until a sample dissolved in diluted hydrochloric acid takes a still bluer colouring; the action will generally require about three hours for completion. From the reaction-product the portion of paraphenylenediamine not used up is extracted by boiling with water. The residue is then dissolved in 2,000 parts by weight of water and 70 parts by weight of hydrochloric acid of 30 per cent. at a raised temperature, the solution is filtered, and the colouring matter is precipitated by means of common salt. The colouring matter dyes mordanted and non-mordanted cotton blue tints. Claims: The manufacture of colouring matters of the induline series soluble in water, by heating with aromatic meta- or para-diamines the induline soluble in spirit which in the production of the induline $C_{24}H_{18}N_4$ is formed conjointly therewith.—No. 1699. January 31st, 1890. 4*d*.

EXPLOSIVES.—*J. Y. Johnson, London.* (*C. Pieper, Berlin, Germany.*)—The invention relates to the manufacture of gunpowder from nitrocellulose or from compounds thereof with nitrate of potash, camphor, or other substances capable of accelerating or retarding combustion. The following is an example of the process embraced by this invention:—20lb. of nitrocellulose with or without admixtures are put into a dough-kneading machine, 20lb. of acetic ether, or of a mixture of alcohol and ether, are added, and the machine is put in operation. After the kneading has been continued for about one hour the nitrocellulose is dissolved and a gelatine-like mass is obtained; 10lb. of water having a temperature of about 60° C. are then poured upon the mass, which causes the division of the gelatine into grains in a few minutes. In order to expel from these grains the solvents employed, they are exposed to a hot liquid or vapour incapable of dissolving or acting chemically on the substance of the grains, the temperature being carried to a degree somewhat above the boiling point of the solvent so as to ensure its complete expulsion by evaporation. After having been separated from the liquid the grains are dried and finally treated in the ordinary manner for producing finished gun or blasting powder. Claims: The process of gelatinising and granulating nitrocellulose or a compound thereof with other substances substantially as described in two claims.—No. 2547. February 17th, 1890. 6*d*.

MISCELLANEOUS.

COATING WIRE WITH TIN.—*F. Baker, Aston, Warwickshire.*—To effect the above purpose the inventor takes a loose coil of steel or iron wire, and by means of electro-deposition coats it with tin in the ordinary manner, so obtaining a much more even coating than by the usual method of dipping the coil into a fluid bath of tin. The coil is then placed upon a swift or reel, from whence it is drawn through a suitable die or dies to smooth and finish the wire, which is effected by means of a revolving block, drawing the wire through the die in the ordinary manner. Claims: The process of manufacturing coated iron or steel wire substantially as described.—No. 14591. September 16th, 1890. 4*d*.

BRAKE MECHANISM FOR LIFTS.—*A. J. Boult, London.* (*G. Backman, Paris, France.*)—The object of the invention is to prevent the cage falling in case the supporting ropes or chains break. The accompanying illustration shows a lift fitted with the improved brake mechanism. A are the two supporting ropes, which, passing through the lower part of the cage, have their ends fixed to levers on a rod B, so holding it in the position

shown. Each end of B has a crank C, to which is connected a sliding rod D carrying a bracket E, embracing loosely an internally threaded collar F, which works on the screw-threaded rods G fixed at each side of the lift. Attached to each side of the cage is a bracket H, through which the rods G also pass. The opposite faces of F and H are bevelled to fit one another. The operation is as follows:—Should the cords A break the rod D would be freed. The cage and bracket E would commence to descend at a greater speed than the collar F, owing to the friction of the latter upon the rods G. The two faces of F and H, therefore, come in frictional contact, so preventing F from revolving and consequently stopping the downward travel of the cage. Three claims are made, embracing the apparatus as described, with modifications.—No. 18602. November 20th, 1889. 8*d*.

TREATMENT OF TIN REFUSE.—*T. Teague, Pinwood, Devoran, Cornwall.*—By this invention the natural alloys of tin and other metals resulting from the refining of smelted tin in the ordinary manufacturing process, technically known as "hard head," are melted with copper or any alloy containing copper in any proportion required, by which an exceedingly hard bronze is formed, which is very suitable for machine bearings, wire, and all the purposes to which bronze is at present applied. The inventor prefers to use a proportion of "hard head" of about 10 per cent. Claims: To make bronze by melting "hard head" with copper or any alloy containing copper in any proportion required.—No. 19687. December 7th, 1889. 4*d*.

Copies of the British specifications may be obtained on application to* H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.

ENGINEERING PROGRESS IN 1890.

GENERAL MECHANICAL ENGINEERING.

The completion of the Forth Bridge may be claimed as one of the triumphs, not only of civil, but also of mechanical engineering. The special tools which were designed, chiefly through the ingenuity of Sir William Arrol, and the methods of construction which were adopted were all essentially connected with mechanical engineering, and their study will be found to embrace almost every department of the profession. For details of these, however, we must refer to the very complete descriptions which have appeared in our columns and in those of other technical journals, and to the proceedings of various Engineering Institutions, in which they are described.

In the department of steam engineering there has been no striking invention or new development, although progress has been made in the use of higher pressures of steam, and consequently in the construction of boilers. In marine engineering the triple and quadruple systems may be said to have displaced the ordinary compound for all practical purposes. Of the former, the engines of the White Star liners, the "Teutonic" and the "Majestic," may be taken as examples of the best practice. They are of about 17,000 horse-power, and propel the ships by means of twin screws. The cylinders are not steam-jacketed, for the experience of Messrs. Harland & Wolff has confirmed the opinion we have expressed on the subject, that in marine engines in which the steam is used in three or four cylinders there is no advantage to be gained from jacketing—in fact, that very often the reverse is the case, for unless the steam is constantly renewed the jackets get filled with water. To prevent this contingency—at least, by means which would be at all economical—is a work of considerable difficulty. The cylinders are, however, fitted with liners, and are air-jacketed. In the construction of the engines many improvements have been introduced in design and construction. There is now a tendency to simplification in the construction of marine engines by causing many of the subsidiary parts to be practically self-contained. For instance, in the engines we are considering the condenser is quite separate, and, being made of brass, is comparatively light, although the aggregate length of tubes is said to be about twenty miles. The circulating pumps are also distinct, and are of the centrifugal form, by Messrs. Tangye, of Birmingham. The air pumps, however, are worked from back levers from the high and low pressure engines. The two sets of engines are quite distinct, and are separated by bulkheads. In the "City of Paris," however, this arrangement was not found to be sufficient, and the connecting rod of the disabled engine drove a hole through the bulkhead and caused both engine-rooms to be flooded, but it is difficult to conceive any design that would stand in such circumstances.

Of the smaller kinds of marine engines the quadruple-expansion engines made for torpedo boats by Messrs. Yarrow & Co., of Poplar, may be mentioned as examples of the most recent practice. The boilers are of the loco-marine type which have been made by this firm for some years. The engines are quadruple expansion, and the cylinders are placed, not in pairs, as is usually the case, but in a line, in order that the vibration which is so common in high-speed engines may be reduced. The order of arrangement is high, second intermediate, first intermediate, and low. As in the large passenger ships, so in torpedo vessels, the main engines are relieved, as far as possible, of all subsidiary work, which is performed by six auxiliary engines, and, notwithstanding all this, there is fair accommodation for the men, even in small boats of this description. The speed obtained from these boats is over 24 knots per hour. In connection with torpedo boats may be mentioned the water-tube boilers made by Mr. Thornycroft, which are a distinct advance in some respects, giving, as they do, great heating surface with small weight.

The use of triple and quadruple expansion engines is now becoming common for other than marine purposes, and especially for pumping and manufacturing. During the year we have given illustrations of typical examples of the various kinds, and we must refer to these for details.

Valve gears are the parts which seem to engage the attention of engineers to a very great extent. Visitors to the Paris Exhibition in 1889 must have been struck with the great variety and ingenuity of the designs. We have reprinted a paper by Mr. J. J. Harper (see *Industries*, Vol. IX., page 520), which gives a good account of the most important, and to which we would direct the careful attention of our readers.

Considerable developments have taken place in the design of small motors of various kinds, including steam engines, hydraulic motors, gas engines, and motors worked by compressed air. Among steam engines those for agricultural purposes, in which portability and ease of management are preferred to economy, have received most attention, chiefly on account of the publicity afforded them by agricultural exhibitions. The designs for gas and air engines continue to increase, and during the year we have given a considerable number of new designs, but none of them seem to call for any special notice.

In locomotive engineering there has been nothing strikingly new, although a study of the various designs which have been produced shows many points of improvement. Compounding of locomotives does not seem to be receiving so much attention in this country from railway engineers as it does on the Continent, especially in France and Germany. The question of the best railway brake may still be considered an undecided question, although the field is now considerably narrowed by the disappearance of many competitors for the position. Some time since a trial was made on the Indian State Railways, but from the reports which were published of them nothing decisive may be expected. There is little excuse for indefinite information on this subject, as appliances are now available which record the whole behaviour of a brake during a trial with the utmost accuracy. This is a subject which we think might be taken up by the Board of Trade and settled in a satisfactory manner.

Machine tools and appliances of all kinds continue to be designed and developed, which display great skill in design and excellence in workmanship, as can be seen from a perusal of our pages. We must confess, however, that in some respects the Americans keep ahead of us in labour-saving appliances. They are not behind either in originality of design for engines and machines of all kinds. On the Continent also we have very keen competitors in every department of mechanical engineering. This was brought out very distinctly by the exhibits of the Paris Exhibition, and especially by those from Switzerland, which embodied good designs with first-class workmanship. Those who were qualified to give an opinion on the subject attributed this in great part to the excellent opportunities which the Swiss have for technical education.

SHIPBUILDING AND MARINE ENGINEERING.

England and Wales.

In reviewing the shipbuilding industry a year ago we stated that it "would be safe to prognosticate another output exceeding one million tons," and now that 1890 has closed it is found that, in round figures, its output has been about one and a quarter million tons—practically identical in extent of tonnage to that of the year 1888. It will be interesting to see if "history will again repeat itself" by a severe falling off in production during the current year. Had it not been for the "rush" of orders that occurred a few months ago, it would have been tolerably safe to prophesy an output for 1891 of the same extent as that of 1884—viz., three-quarter million of tons—but this, we hope, will be exceeded, and there is some reason for the anticipation, especially in the fact that there is a large amount of British Government work in the hands of private contractors, which will assist to swell the output of the current year.

In the accompanying tables we show a summary of the work in England and Wales, giving the individual outputs for the last year of each shipbuilding firm at the seven principal shipbuilding centres. It will be seen the Tyne continues to lead the way as the most active shipbuilding river; but whereas in 1889 the output increased 68,000 tons, it has during the last year fallen over 46,000 tons, the Wear having a smaller decline—under 20,000 tons—thus becoming a better second. The Tees and West Hartlepool stand alone amongst the English shipbuilding centres in having not decreased but increased outputs, the former having improved upon the year 1889 by over 17,000 tons and the latter by nearly 14,000 tons. The Humber has suffered severely, its output being less than half that of the previous year. On the whole the returns for the Mersey are not unsatisfactory, as out of the seven vessels built by Messrs. Laird Bros. five were war vessels for the Chilian and Argentine Republics; still shipbuilding and marine engineering cannot be described as flourishing at this centre. Barrow-in-Furness, of which a special tabular return would be given, were it not that the entire output of the port is that of the Naval Construction and Armaments Company, Limited, has fairly held its own, when it is remembered that the tonnage launched included three cruisers for the British Admiralty, viz., H.M.S. "Latona," H.M.S. "Melampus," and H.M.S. "Naiad." This company's output of marine engines is also swollen by the new engines and boilers supplied and fitted to the steamers "Araucania" and "Patagonia."

There have been no startling departures in practice during the year that has closed. Steel continues to be the principal material for shipbuilding, although for small merchant and fishing craft iron yet retains considerable popularity, and will probably continue to do so. In marine engineering quadruple-expansion engines have been constructed by a few firms, viz.:—Messrs. Wigham Richardson & Co., Walker; Messrs. Wm. Allan & Co., Sunderland; Messrs. George Clark, Limited, Sunderland; Messrs. Yarrow & Co., Poplar; and Messrs. Simpson, Strickland, & Co., Dartmouth. The present depression in the freight market may stimulate a demand for increasing economy in coal consumption, and lead to a wider adoption of higher working pressures of steam and four-cylinder engines. So far, 200lb. pressure is the greatest that has been adopted, and only in a few instances. Experience is, however, being gradually accumulated, and as hitherto the quadruple-expansion engine, when well designed, has given, even with comparatively low-pressure steam, satisfactory results, there appears to be little doubt that in time the "quadruple" will supplant the "triple" expansion engine.

TABLE I.

SHIPBUILDING IN ENGLAND AND WALES.

Rivers or Ports.	No. of Vessels.	Tonnage of Sailing Vessels.	Tonnage of Steamers.	Total Tonnage.	I.H.P.
The Tyne	127	228	234,834	235,062	204,251

Scotland.

Although 1890 shows one of the largest outputs in shipbuilding and marine engineering on record, still in Scotland about the usual proportion has been done, and the Clyde has maintained its pre-eminence amongst the shipbuilding centres. The following figures show how the production of the various centres in Scotland stand in 1890 as compared with the previous twelve months :—

	1890. Tons.	1889. Tons.
Clyde	361,518	335,201
Forth	32,900	33,859
Dundee	24,494	18,311
Aberdeen	9,228	9,470

In previous years we have given a table showing the growth of the Clyde shipbuilding trade. This may be repeated, with the addition of the past year, and the following figures show the Clyde production during the last thirty-one years :—

	Tons.		Tons.
1890	361,518	1874	262,430
1889	335,201	1873	232,926
1888	280,037	1872	230,347
1887	185,362	1871	196,229
1886	172,440	1870	180,401
1885	193,453	1869	192,310
1884	296,854	1868	169,571
1883	419,664	1867	108,024
1882	391,934	1866	124,513
1881	341,022	1865	153,932
1880	241,114	1864	178,505
1879	174,750	1863	123,262
1878	222,353	1862	69,967
1877	169,710	1861	66,801
1876	174,824	1860	47,833
1875	211,824		

So that 1890 stands third on the list as regards amount, being only surpassed by the great years of 1882 and 1883. Unfortunately, the last of the great orders came at the end of 1889, and while during the first half of 1890 the production was enormous, the scarcity—indeed, the almost total absence of new work—rendered the prospect very gloomy. In August, however, an unexpected improvement took place, and a considerable number of orders were placed at all the chief ports, and at prices which, considering the depressed state of the freight market, must be considered fairly good. The prices of materials are less than they were a year ago, but wages are maintained, and the price of labour has been considerably increased by the irregular working of the men. If prices fall, or even if few new orders come in, the question of a reduction of wages must be seriously faced, and it is to be hoped that sufficient common sense will prevail to bring about a readjustment without resort being had to strikes.

The first table in the next column gives details of production on the Clyde and neighbourhood during the past year, and a comparison with the previous year.

The total number of 303, as compared with 249 for the preceding year, shows that the average tonnage was smaller last year than in 1889. Messrs. Russell & Co. again head the list, with a record which we would imagine will stand for some years to come—namely, 70,370 tons. That firm has now two yards in Port Glasgow and one in Greenock, and seems to have got a firm hold of the trade in the larger sailing vessels, for of the thirty-four vessels launched twenty-six were sailing vessels with a total tonnage of 50,634, but none were of any design or construction requiring special notice. During the year we have given details of the more important vessels launched from Clyde yards, so that all that is necessary now is to to recall a few of the more important. From the Fairfield Company's yard there were several notable vessels—for instance, the "Normania," for the Hamburg-American Steam Packet Company; the "Dunottin Castle," for the Castle Mail Packet Company; and three steamers for the Norddeutscher Lloyd, of Bremen. Messrs. J. & G. Thomson, of Clydebank, completed seven vessels, of which three were warships, two second-class protected cruisers for the British Government and one cruiser for the Government of Japan. They also constructed three fast twin-screws for the London and South-Western Railway Company's Channel Islands passenger service. Messrs. Denny & Co., of Dumbarton, had several splendid specimens of river passenger, such as the "Duchess of Hamilton," for the Clyde service of the Caledonian Railway Company, the "Clacton Belle," for the London, Woolwich, and Clacton-on-Sea Steamboat Company, besides a number of large steamers for Indian and Colonial service. In glancing over the lists of the other builders, notwithstanding the large output, we do not see much calling for special remark, as the majority of the vessels are intended for ordinary passenger or goods traffic.

	1890. Vessels.	Tons.		1889. Vessels.	Tons.
Messrs. Russell & Co., Greenock...	34	70,370	...	21	46,500

	303	361,518			

On the Forth the work done during the year was somewhat less in amount than that done during the preceding year, as is shown by the following figures :—

	1890. Vessels.	Tons.		1889. Vessels.	Tons.
Grangemouth Dockyard Company	18	17,155	...	14	14,047
Ramage & Ferguson, Leith	6	8,584	...	9	13,036
S. & H. Morton, Leith	4	3,641	...	5	4,090
Messrs. Hawthorns, Leith.....	6	800	...	2	680
Jno. Scott & Co., Kinghorn	5	2,720	...	8	1,006

In Dundee the output was larger than in 1889, and included the "America," built by Messrs. Gourlay & Co. for the National Steamship Company, which is the largest vessel ever launched on the Tay. The following are the details of the different yards for 1889 and 1890 :—

	1890. Vessels.	Tons.		1889. Vessels.	Tons.
Messrs. Gourlay Bros. & Co.	5	11,616	...	6	8,333
Messrs. W. B. Thompson, Ld.....	8	8,466	...	6	8,470
Messrs. A. Stephen & Sons.....	2	4,415	...	2	1,508

In Aberdeen the production was about the same as in 1889, the following being the figures :—

	1890. Vessels.	Tons.		1889. Vessels.	Tons.
Hall, Russell, & Co.	8	5,684	...	5	5,770
A. Hall & Co.	4	1,595	...	5	3,320
John Duthie, Sons, & Co.	3	1,949	...	2	380

The total indicated horse-power of the engines constructed in Scotland during the year 1890 was 422,778, and the following table gives abstracts of the returns :—

	I.H.P.
Fairfield Company, Govan.....	53,950
J. & G. Thomson, Clyde Bank	44,300
W. Denny & Co., Dumbarton	37,850
Muir & Houston, Kinning Park	18,975
Dunsmuir & Jackson, Govan	17,450
Fleming & Ferguson, Paisley	17,150

Digitized by Google

	I.H.P.

John Duthie, Sons, & Co., Aberdeen	2,150
Hawthorns & Co., Leith	2,620
A. Hall & Co., Aberdeen	1,580
Alley & M'Lellan, Glasgow	1,060
Hanna, Donald, & Wilson, Paisley	1,050

These figures represent not only the engines made for the vessels built in Scotland, but also for a considerable number built in England, and other parts of the world. For instance, the engines and boilers for H.M.S. "Edgar" were constructed by the Fairfield Company, while the vessel itself is being built in one of the dockyards. Some of the makers of the smaller sizes of engines export them in considerable numbers to foreign countries, where the hulls are being constructed. A very large proportion of the vessels launched during the year were, as usual, for foreign owners, so that the progress of other nationalities in marine engineering and shipbuilding has not been sufficient to affect our trade to any material degree. The following table gives the number and gross tonnage of the vessels built in Scotland in 1890 for home and foreign owners:—

	Vessels.	Tons.		Vessels.	Tons.
Germany	13	45,317	Japan	2	2,990
Norway	18	19,727	South Africa	3	1,060
France	8	12,940	Other countries	6	3,040
Belgium	4	7,153	London	37	65,183
Spain	4	5,806	Liverpool	23	46,015
Greece	1	1,223	British Government	2	7,000
Portugal	1	699	English ports	22	12,053
North America	6	9,835	Glasgow	65	89,801
South America	14	7,485	Scotch ports	42	49,406
Australasia	11	16,670	Ireland	6	5,229
China	2	3,996			

There is still considerable work on hand, but, as few orders are coming in, that will soon be completed, and the prospects are not particularly bright; but it is possible that during the present year a considerable number of fresh orders will come in.

Ireland.

The output in 1890 at Belfast is less than that in 1889, but it ought to be remembered that in that year the "Teutonic" and "Majestic," both of very large dimensions, were launched from the yard of Messrs. Harland & Wolff. The following table gives the production of the different yards for the two last years:—

	1890. Vessels.	Tons.	1889. Vessels.	Tons.
Messrs. Harland & Wolff, Ld.	13	48,633	12	56,430
Messrs. Workman, Clark, & Co., Ld.	10	15,631	7	17,710
Messrs. MacIlwaine & M'Coll, Ld.	5	2,105	8	8,883
Messrs. Paul Rogers & Co., Carrickfergus	4	414	—	—

At Londonderry Messrs. J. C. Biggar & Co. launched from the Foyle Shipbuilding Yard one steamer of 3,318 tons, and four sailing vessels aggregating 7,276 tons, making for the year a total of 10,594 as compared with 7,268 for 1889.

CIVIL ENGINEERING.

Bridges.

The most important work in civil engineering which was completed in this country during the past year was undoubtedly the Forth Bridge, a structure which embodies almost every department of constructive skill, and which is the crowning work of the railway system of the country. On the 24th January, 1890, the first train was driven across the structure, and on the 4th of March the opening ceremony was performed by the Prince of Wales. We devoted so much space to a description of the bridge, not only in our ordinary issues, but also in a special number, that it is altogether unnecessary to enter into details, but we may note a few of the chief facts connected with it. Its extreme length, including the approach viaduct, slightly exceeds a mile and a half, and the actual length of the cantilever portion of it is a little over a mile. The weight of steel used in it amounts to 54,000 tons, and the extreme height of the structure above mean water level is over 370ft. above high-water mark, and above the bottom of the deepest foundation 450ft., while the rail-level above high water is 156½ft. The entire cost of the structure has been about three-and-a-quarter million pounds sterling, and notwithstanding this large amount we are pleased to learn that the traffic which is passing over the bridge is even now sufficient to afford a fair return for the money invested, and of course this will go on improving, as the completion of the bridge must necessarily lead to important changes and developments in the railway service of the East of Scotland. Everybody, therefore, connected with the Forth Bridge, engineers, contractors, and railway directors, are to be congratulated on the success of the undertaking, both from an engineering and financial point of view.

The Tower Bridge over the Thames has been several times referred to in our current issues. It is making satisfactory progress, and promises to be of great use. Its design and construction embody many novel features, which we have explained on previous occasions.

Canals and Ship Railways.

The most important civil engineering work which is now being carried on in this country is the Manchester Ship Canal, of the progress of which we give a special account in another column, and have also given detailed accounts, from which our readers would see that it is being pushed on with energy and vigour, with the aid of the best skill and the most improved engineering appliances, and there can be little doubt of its successful completion, and ultimately of its financial success.

For a good many years past, in reviewing the progress of civil engineering, the Panama Canal has always received a considerable amount of attention. This year it is a blank, for all work has been suspended on account of the financial collapse of the company. It has been always very difficult to pronounce a definite opinion either on the financial or the engineering aspects of the undertaking on account of the contradictory reports which have been published regarding it. We have on various occasions pointed out the engineering difficulties which did not seem to be faced by those in charge. The report recently issued by the financial liquidator seems to prove that the undertaking has existed, not so much for the benefit of the shareholders, as of the financiers and promoters, who have managed to secure a very large share of the total capital subscribed. The latest reports are that an agreement, extending the period within which the Panama Canal is to be completed, has been signed by the Columbian Government and by a representative of the liquidators of the Panama Canal Company, so that evidently the undertaking has not been given up.

The rival scheme to the Panama Canal—that is, the Nicaraguan Canal—seems to promise an early completion and financial success. The concession to the company has been ratified by Nicaragua, and is favoured by the United States Government. The undertaking is now backed by some of the most influential men in the United States. During the past year over $3,000,000 have been expended on the work, and the progress which has been made seems to indicate that the canal will be completed within six years. The total cost of the undertaking is estimated at $64,000,000, an amount which is thought by some well-informed persons to be less than one-half of what is still required to complete the Panama Canal. The success of the Nicaraguan scheme will add to the difficulties of the Panama Company, for it will have a competitor which will have all the advantages of a very much smaller capital.

As we have pointed out several times during the year, canals and inland navigation generally seem to have entered on a new era of activity under conditions suited to the requirements of modern times. The subject received great attention at an important conference held in Manchester in July of last year, and which was attended by eminent engineers from the chief European countries, who discussed, not only the general conditions of the problem of inland navigation, but also many proposed works. We must refer our readers to an account of the proceedings for details, but we have no doubt that the conference helped to bring to a point many schemes which were floating indefinitely about. There were competing plans for a new Forth and Clyde Canal, which we would have liked to have heard discussed more fully from an engineering and also from a financial point of view. Details were given of a proposed ship canal between Birmingham and Liverpool, which, if carried out, would be of great importance to the trade and commerce of the country. Many other schemes have been mooted. The North Staffordshire Railway Company are applying for powers to enlarge the Thames and Mersey Canal, so as to make it available for larger vessels, and is intended to join the Bridgwater Canal at Preston Brook. The Aire and Calder Navigation is also to be connected with the proposed canal from Sheffield to the Humber. But improved canals are not to have it all their own way; these are likely to have competitors in ship railways, and especially in that form designed by Mr. William Smith, of Aberdeen. Mr. Smith, like other enthusiasts, sees opportunities for the application of his invention, not only in various parts of this country, but in many parts of the world. In company with Mr. W. R. Kinniple, he has made a survey of a route to connect the Bristol and the English Channels, and they consider that a ship railway might be constructed for £35,000 per mile sufficient to accommodate vessels of 1,000 tons burthen, and a syndicate is about being formed to carry out the project. If it turns out a successful scheme, it will no doubt lead to many others. Ship canals and railways are being introduced in several parts of America, and others are being proposed.

Dock, Tunnel, and Harbour Works.

Means of communication are being improved to meet increasing traffic, and these include great varieties of design. One of the most novel is the elevating ferry boat which has been placed on the Clyde at Finnieston, and which was designed and built by Messrs. Simons, of Renfrew. It has been most successful since it was placed on the station, and has carried a large amount of heavy and passenger traffic. At the same part of the Clyde a subway is being constructed by a private company.

There is a proposal for a tunnel to connect Ireland and Scotland, but as yet it is "in the air." Bridges and tunnels of all methods of design have been constructed in many parts of the world, but for details of these we must refer our readers to the proceedings of the Engineering Institutions.

Considerable extensions have recently taken place in the dock accommodation both on the Mersey and the Clyde. For an account of the former we refer our readers to Vol. C. of the Minutes of the Proceedings of the Institution of Civil Engineers, which also contains much useful information regarding the Bars of Tidal Estuaries, and the very complete papers on the Shanghai, Hong Kong, and Yokohama Water Works, which ought to be carefully studied by all interested in hydraulic engineering. The new water works for Manchester are making good progress, and so also is the extension of those for Glasgow.

Railways.

In the department of railway engineering the year 1890 was remarkable for the number of projects put forth rather than for the actual work done. The most ambitious scheme is the proposed extension of the Manchester, Sheffield, and Lincolnshire system to London, and practically means a new trunk line into London. No doubt it will be most vigorously opposed by the other companies, but if carried out it will be a great convenience to a very large district. There are various proposals for the extension of railway accommodation in the metropolis and neighbourhood and on the part of the great trunk companies of the country, but these do not call for any special remark. As regards Scotland, there is the Highland Railway which we commenced to describe on page 12 in our issue of last week. The people of Edinburgh are distracted by the competing plans of the North British and the Caledonian Companies. It is certainly time that something were done by both companies, as the terminal stations in that city are a disgrace to all concerned. The railways of America make steady progress, but in these our iron and steel manufacturers have now little interest, as their wants are supplied from American sources. Those of India are of much more importance to the iron and steel industries of this country, and it is satisfactory to find that not only are they being developed at a considerable rate, but also that the traffic is sufficient to enable them to pay good dividends. It is a fact to be noted that in ten years the traffic on Indian railways has more than doubled. The Chinese have done practically nothing to justify the great expectations which some people had formed of their wishes and requirements, thus proving that the opinions we have frequently given on the subject were correct. China will have railways, but it will be by a comparatively slow process, and by utilising native labour and resources as far as possible. On the other hand, the Japanese are going ahead at a rapid rate, and in 1889 had 1,000 miles open for traffic. A great part of the rails and the rolling stock came from this country, but for some years past the construction has been carried out almost entirely by native engineers, and with very good results. Considering that it is only twenty years since the first lines were contemplated by the Japanese the progress they have made is very creditable.

On the whole, the work done in the department of civil engineering in the year 1890 has not only been of great importance and variety, but also opens up prospects of wider developments in the future.

IMPROVED FORESTRY MACHINERY.

CONSTRUCTED BY MESSRS. ARBEY & FILS, MACHINISTS, PARIS.

(*For description see next page.*)

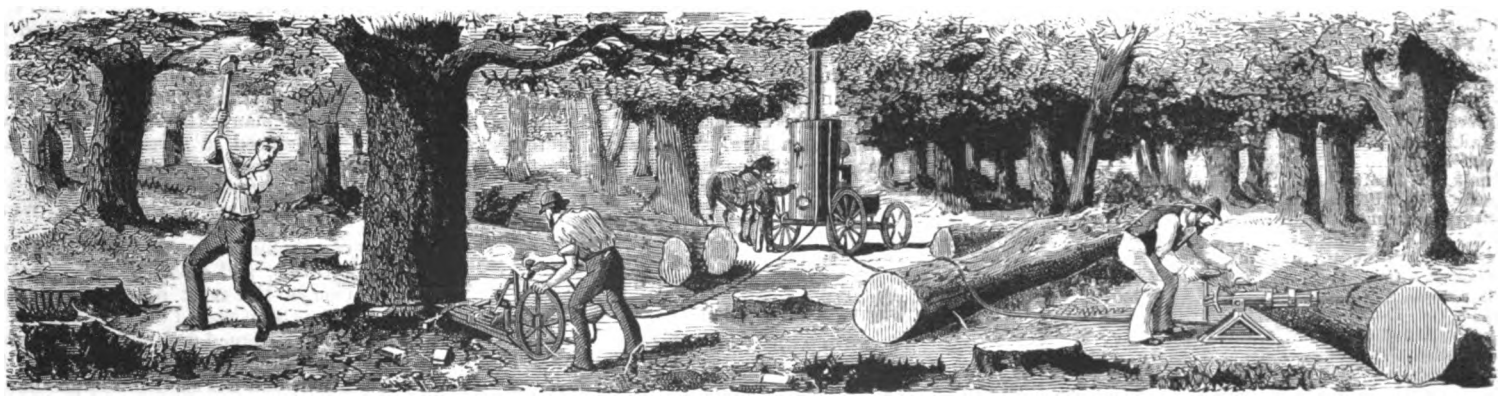

FIG. 1.—GENERAL VIEW OF MACHINES AT WORK.

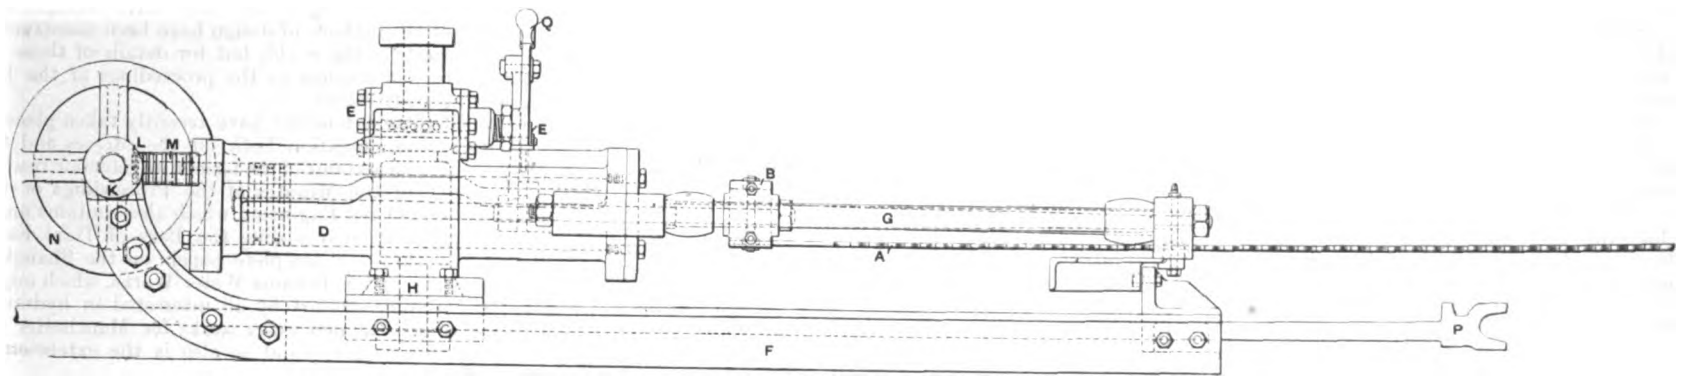

FIG. 2.—SIDE ELEVATION OF TREE FELLING MACHINE.

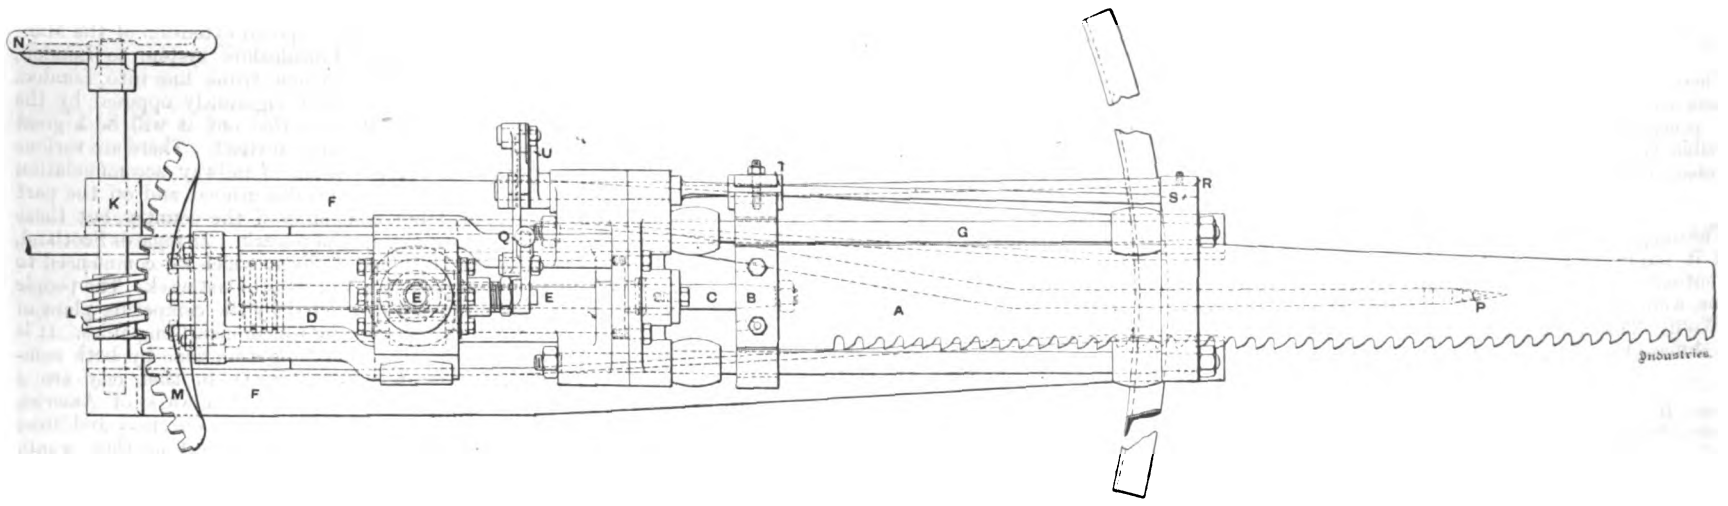

FIG. 3.—PLAN.

THE PROGRESS OF THE MANCHESTER SHIP CANAL IN 1890.

CONSIDERABLE progress has been made in the entire length of this great undertaking during the past twelve months, and but for two unfortunate accidents the works would have been still further advanced. Owing to the very heavy rainfall at the end of September, the River Mersey rose so rapidly as to overflow its banks and wash down the barriers at the end of the cutting near the Barton Aqueduct, thus flooding a long length of the canal. Arrangements were made for retaining the water in the portions of the canal which were finished and pumping out the remainder. Scarcely had these works been completed, when, on the 7th of November, a more serious disaster occurred from the same cause, and the whole length of the canal from Manchester to Warrington was flooded. Fears were entertained on the day previous to the accident that such a disaster might happen, the Mersey waters having risen so rapidly and to such an abnormal height; and at midnight the bank burst and the water rushed with tremendous fury along the cutting of the canal, washing away temporary bridges, culverts, and submerging every description of plant. In a very short space of time there was an average depth of water in the canal of about 25ft. Owing to the timely warning there was fortunately only one life lost—that of the driver of a locomotive, who could not escape in time—but there were some almost miraculous escapes.

The number of men and boys now engaged upon the works is nearly 17,000, and with this manual labour, in addition to the enormous amount of machinery and plant, it is no wonder that the work has progressed so rapidly. The works at Eastham are far advanced, the gates for the series of locks are made, and many of them are fixed in position. The large pumping station for supplying hydraulic power is nearly completed, and the well-boring, for obtaining the water for the pumps, is proceeding satisfactorily, the bricked portion of the shaft having reached the full depth of 60ft. The lock walls are nearly completed, and a good idea of the great capacity of the lock can now be formed. The cutting at Pool Hall is proceeding rapidly, but has received a slight check on account of the percolation of the water through the sandstone into the workings. The piling at Ellesmere Port and the formation of the bank is progressing slowly, but this work is very heavy. The banks along Frodsham shore have been slightly damaged by the storms, but are now being repaired. The works opposite Runcorn, which had been almost at a standstill for some time, are now actively in progress, and the piling for the river wall is far advanced. The inner rubble bank across the Weaver to the sluices has been tipped almost to the masonry of the sluices, the space between being filled with clay. The piling of the jetty from the Frodsham side to the sluice gantry has been commenced, and, when completed, will form a continuous path across the Weaver at any state of the tide. The lock entrance at Runcorn Old Quay is proceeding slowly. At Acton Grange the bridge stone piers are gradually rising, and the swing bridge at Moore Lane is approaching completion. At Latchford great progress has been made, and this is one of the most interesting sections on the canal, on account of the diversions of the railways, and locks. The Grappenhall Road Bridge is completed, and the others near are well advanced, the Cross Lane

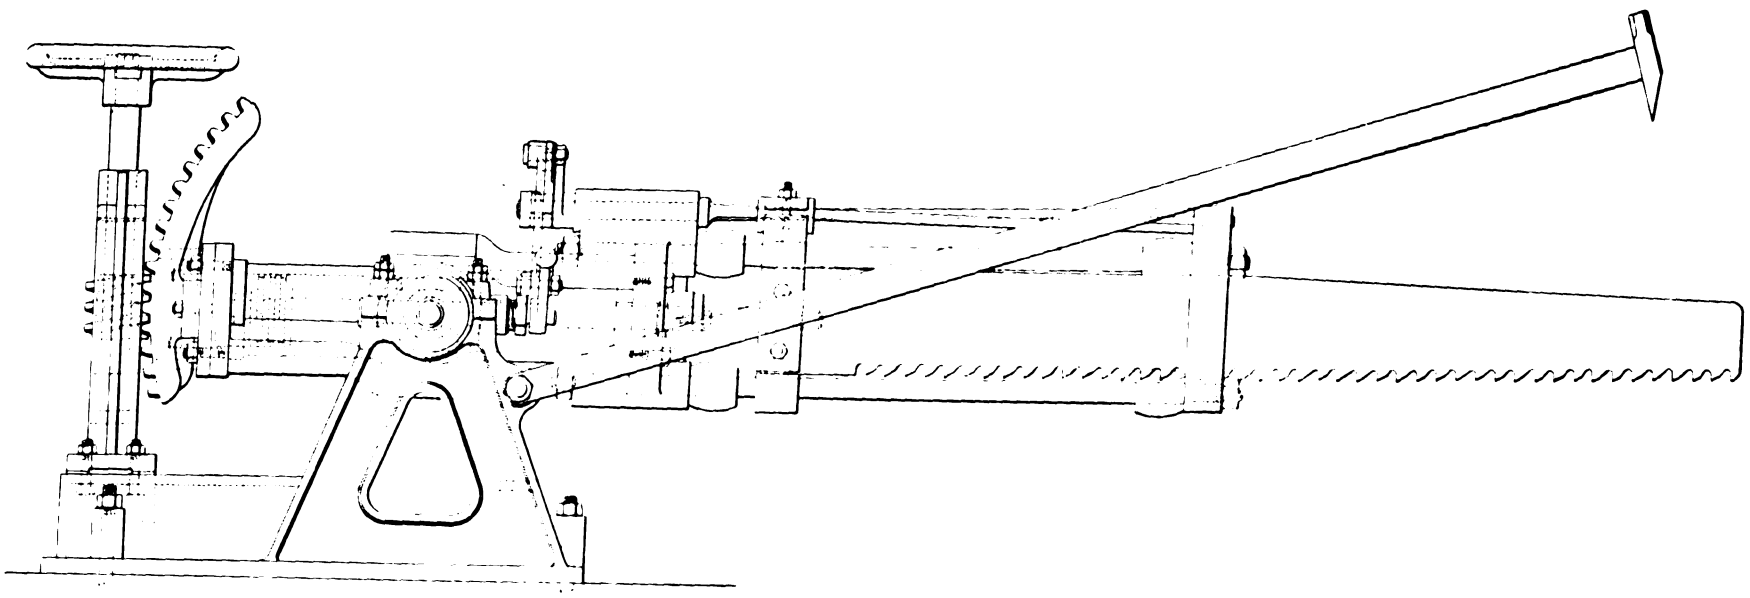

FIG. 4.—SIDE ELEVATION OF LOG CUTTING MACHINE.

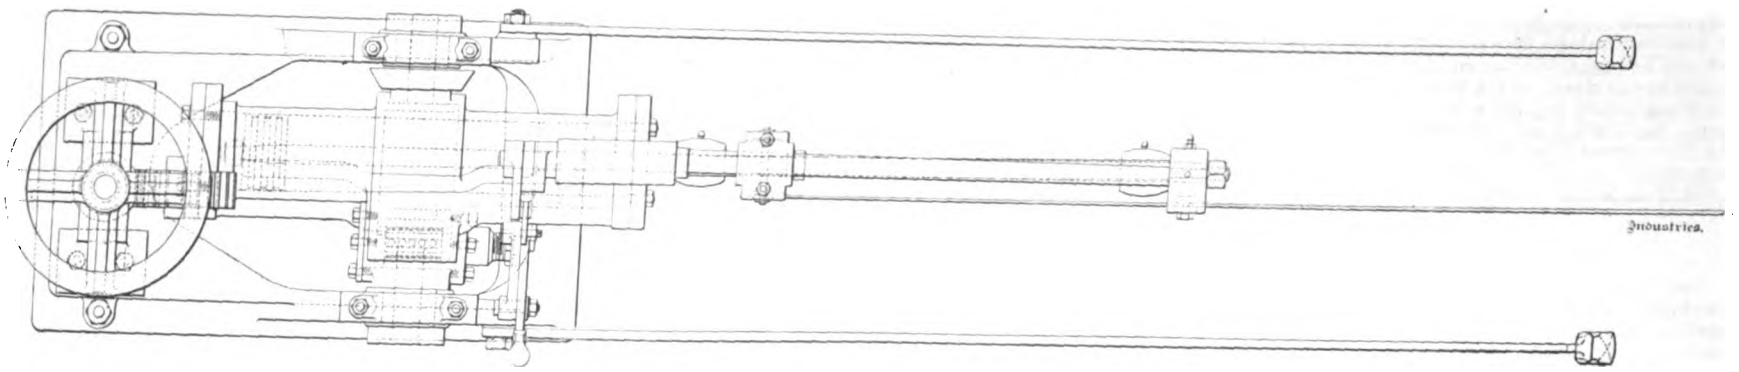

FIG. 5.—PLAN.

Bridge piers—the heaviest piece of brickwork on the canal—being up to their full height. The Irwell Park cutting is excavated to its full depth, and has been a laborious piece of work. The old locks and weir at Irwell are now demolished, and steam navvies are excavating the bottom of the canal eastwards. The arches of the viaduct at Irlam are nearly completed, as also is the girder bridge over the river. The Mode Wheel Locks are far advanced, and the masonry for the sluice piers is well in hand. The piling in the river for the Stretford jetty is well advanced, a third row of piles having been commenced. The pier for the free end of the swing bridge at Old Trafford is being completed, and is now up to the fender course. An American steam navvy is clearing away the face of it, and shortly the proportions of this massive concrete wall will be seen. The walls of the various docks at Pomona and Salford are near completion, and granite steps are being fixed at convenient places. The work throughout is in a very forward state, and great credit is due to the engineer and his staff, who, while working harmoniously with the contractor and his staff, have made such great progress since the work began in the face of so many obstacles.

As regards the financial condition of the scheme, the following statements, made by Sir Joseph C. Lee, the deputy chairman, may be of interest:—He stated that in 1885 the capital of the company was £10,000,000; in 1886, upon a reduction of the borrowing powers, it was £9,812,000; £1,700,000 was paid for the Bridgewater Canal; £5,570,000 for construction; £750,000 for land; interest on shares, £750,000, making a total of £7,250,000, leaving £852,000. After deducting for more land purchase, Parliamentary expenses for the 1885 Act, £450,000 remained for general working. They had to receive of the capital granted by the 1885 Act £2,952,487, and with the borrowing powers of the 1890 Act £600,000, making a total of £3,532,487. Assuming the profits of the Bridgewater Canal to be £300,000, the amount is raised to £3,832,487, and as £704,030 of this amount is already spent, the amount left to complete the canal is £3,128,457.

IMPROVED FORESTRY MACHINERY.

On the previous page and above we illustrate two machines made by Messrs. Arbey & Fils, Paris, for forestry work. One machine is for sawing down trees, and the other for cutting up logs from the felled trees. In Figs. 2 and 3, which represent the former machine, the saw A is attached to the cross-head B, which slides on the bars G. The cross-head is fixed to the end of the piston rod C of a steam cylinder D, and the motion of the piston in the cylinder produces the vibratory motion of the saw. The cylinder is pivoted at H to the frame F, which carries the whole machine. At the end K of the frame F a worm L works a segment M attached to the cylinder, and thus enables the feed to be given to the saw by means of the hand-wheel N. A claw P attached to the frame is inserted in the tree, and the pull of the saw draws it in more tightly. The end of the saw rests upon a piece of wood until it has got fairly started, and when it is half way through the tree wedges are inserted so as to take off the weight. The alternating motion of the piston is produced in an ingenious manner. The steam is admitted to the cylinder through the circular valve E, which is controlled by the lever Q. A twisted bar R of rectangular section is capable of oscillating, in the bearings S, about an axis parallel to its length. The cross-head B is prolonged, and carries brasses T which compel it to turn about its axis and thus oscillate the lever U. This lever is connected by a link with the lever Q which controls the valve. The action of the log sawing machine, shown in Figs. 4 and 5, is practically the same as that just described, except that the saw works in a vertical instead of a horizontal plane—the steam cylinder being supported upon trunnions. Fig. 1 gives a general view of the two machines at work in the forest. The steam is supplied by a vertical boiler on wheels. The steam is conveyed from the boiler by a strong indiarubber pipe capable of standing a pressure of seven atmospheres. 4 h.p. is required to drive this form of saw.

THE STEEL INDUSTRY IN THE UNITED STATES.

Of all the industries in the United States few, if any, show such rapid development as that connected with the manufacture of steel. From a preliminary report on the subject, which was recently issued by the United States Census Office, we learn that the total production of steel in the United States in the form of ingots or direct castings, during the year ending June 30, 1890, amounted to 4,466,926 tons of 2,000lb., as compared with 1,145,711 tons produced during the year ending May 31, 1880, being an increase of about 290 per cent. A few steel works produce blister, cemented, and other miscellaneous steel, but the quantity is small, and may for our present purpose be neglected. The following figures represent the production of the different kinds of ingots for the year ending June 30, 1890, in tons of 2,000lb.:—

Bessemer steel	3,788,572
Open-hearth steel.....	504,351
Crucible steel	85,536
Clapp-Griffiths steel	83,963
Robert-Bessemer steel.....	4,504
Total	4,466,926

About one-half of the total production—namely, 2,036,654 tons—was in the shape of Bessemer steel rails, although the requirements of other departments of industry have been the cause of the increase of the number of steel-producing establishments during the past ten years, as all those existing in 1880 had been designed for the production of steel rails. The great increase in this production has practically led to the discontinuance of the manufacture of iron rails. Although basic steel was produced experimentally in Pennsylvania in 1884, it is only from March, 1888, that its manufacture as a commercial product dates, and since that time it has made considerable progress.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 6th January, 1891.

Iron.—The downward movement which has characterised the iron market of the capital for some weeks past continues, and, if we may judge from the weak tone now prevailing, is likely to bring prices down to the lowest level of last autumn. Bars are now quoted at 128s., and may be bought for 126s. Joists hold their position more firmly; but, though officially quoted at 136s., the actual price is not above 134s. As a matter of fact joists are but little inquired for. The Grenelle works, finding the market for joists insufficient to absorb their production, are about to commence the manufacture of bars. Old rails are offered at 70s. to 72s. Some of the reports from the provincial markets are discouraging. In the Ardennes business is very languid and prices are giving way. The calm in the Nord continues. The market is somewhat languid in the Haute-Marne. In the Meurthe-et-Moselle the situation is unchanged.

Coal.—An important measure is reported from the north with reference to the coal trade. In view of the depressed state of the iron trade, consequent on the difficulties in which manufacturers find themselves as a result, in large part, of the high price of fuel, the colliery owners of the Nord and the Pas-de-Calais have resolved to reduce their price for coal for metallurgical purposes, while firmly maintaining those of other sorts. This laudable act of self-sacrifice will excite admiration when it is remembered that there are no stocks of coal anywhere, and that the present demand is sufficient to absorb the whole of the output of the collieries. The Longwy group of blast-furnace owners have already purchased large quantities of coke in the Nord in consequence of this concession. The market for household coal is very animated.

Metals.—The general tendency of the metal market is unfavourable. Speculation is at a standstill, and the current of genuine business is weak. Nothing is bought that is not required for immediate consumption. Copper is quoted at last week's rates, but the tone of the market is depressed. Tin is unchanged in price, and the market is without animation. Lead, which was stronger a fortnight ago, has lost the little vigour which then made itself apparent. Spelter is quoted at last week's prices, but hardly any business is being done in that metal. Lower prices are probable.

BERLIN, 5th January, 1891.

Iron.—It is yet too early to expect a renewal of business in the iron market. During the last week manufacturers and consumers have alike been occupied in stock-taking, and for many that task yet remains unaccomplished. Still the market opened to-day with a show of life. The amount of business being done is small; but inquiries are numerous and the tone of affairs good. According to a report from Breslau there are good grounds for expecting a speedy return to activity in that district—not the activity of last year, perhaps, which was exceptional, but a moderately strong current of business sufficient to keep matters in their present position, even if no advance in prices become possible. Similar accounts have been received from the Rhenish-Westphalian districts. Altogether the outlook is encouraging. A heavy blow has been dealt at the syndicate system by which the German iron trade is now controlled by the decision of the Prussian Railway Minister to accept the lowest tenders for steel rails, no matter whether from German or from foreign firms. Recently an English firm tendered 15s. a ton lower than the German firms, duty paid. This decision has caused consternation among the German houses. The financial papers here have, however, greatly exaggerated the probable consequences of this measure in overthrowing the "iron ring." The total imports of foreign pig iron in the eleven months ending with November amounted to 370,578 tons, against 292,734 tons in the corresponding period of last year, the exports of German pig for the same periods being 110,188 tons, against 147,155 tons. German wire was exported to the amount of 120,686 tons in 1890, against 146,195 tons in 1889, wire nails figuring as 36,815 tons against 42,724 tons. There has been a heavy falling off in the export trade in bars.

Metals.—The metal market remains inactive. For several weeks past consumers have refrained from exceeding the bare necessities of the moment in their purchases of metal, and there are no indications of a desire to operate more largely. The new year begins with drooping prices. Copper has lost a little in the last week, and tin has receded several points. Lead shows a downward tendency, and spelter is decidedly weak. The spelter market is languid, and seems likely to be further depressed. Antimony regulus is offered several marks a ton lower.

VIENNA, 5th January, 1891.

The International Electricity Company.—This company has been commissioned by the Ministry of Finance to carry out an installation of electric lighting and of a separate plant for the electrical transmission of power for the purpose of working printing machines for the Government printing office at Rennweg. In both cases the transmission of the power will be effected by means of this company's cable system.—On the 31st ult. the electrical plant of the International Electricity Company in Fiume was set at work. With reference to the erection of this plant, the company lately entered into negotiations with the authorities of Fiume, who, however, refused to grant a concession for the erection of a central station by reason of a protest made by the gas company of Fiume. A suitable site was, however, granted to the company for the recent installation carried out on behalf of the Hungarian Government, and the plant, by means of which the railway station in Fiume is electrically lighted, and power transmitted for the working of the lifts of the Hungarian State Railway, will become enlarged into an important central station for these purposes on Government land. The International Electricity Company will also carry out the electrical lighting of the festival room in the School of Arts on the occasion of the artists' festival and exhibition which is held in connection with it, at the approaching carnival.

BRUSSELS, 6th January, 1891.

Iron.—It would be too much to say that the iron trade has improved in the course of the last week; but there are brighter spots on the horizon—at least, in so far as the home market is concerned. The demand remains feeble, but some important orders are in sight, which serve to raise the hopes of the manufacturers. These orders are chiefly for railway material. The export trade continues languid. Prices are irregular, but, on export account, generally lower. At present rates business is unremunerative. On much that is being done losses will be incurred by the manufacturers, who accept fresh orders at these depressed rates merely to keep their works going. There is but little doing in the pig iron market. Several blast furnaces were blown out at the end of the year 1890. The outlook in this direction is discouraging.

New Line of Steamers.—A new line of steamers, to run between the port of Antwerp and Eastern Asia, is projected, and is likely to become an accomplished fact within a short space of time. The necessary capital has, it is said, been in greater part already subscribed. This new competitor with the German Lloyd cannot fail to have an important influence on European trade. The project has made quite a stir in Germany. English commerce will doubtless be in a considerable degree affected by this new means of communication with a part of the world that is becoming an important outlet for the produce of European factories.

DÜSSELDORF, 6th January, 1891.

Iron.—The pig iron market, long in a languid state, is beginning to revive. We are yet too near to the holiday season to expect active business, and nothing like activity exists. But the demand has increased. Forge pig, which has been utterly neglected for some time past, is now much inquired for. Spiegel, too, is in stronger demand. For other sorts the market remains quiet. Prices are unaltered, and the tone of affairs is strong. There is not much change to note in the market for finished iron and steel, but there are indications of returning life. Joists are in fairly good and apparently increasing demand. There is also a steady, if not strong, current of business in plates. There is not much doing in bars. Some manufacturers have booked a considerable amount of fresh orders within the last three or four weeks, but others complain of an almost total absence of fresh business. The export trade in bars continues slack. The quantity exported in the first eleven months of the current year amounted to 128,722 tons, against 155,252 tons in the corresponding period of 1889. The market is quiet for hoops. Diminished activity is now reported from the foundries. The prospect for the iron manufacturers has been somewhat disturbed by the decision of the Railway Minister to accept henceforward the lowest tender for rails, whether made by German or foreign firms. This decision, which is regarded as a blow aimed at the syndicate system, will cause sharp competition on the part of the English houses which are in the habit of tendering for the rail contracts. At the present rates the German manufacturers are likely to be underbid by from 10s. to 15s. a ton.

Coal.—The continued frost has further increased what was already exceptional activity in the coal market. Production is being pushed to the utmost allowed by the carrying capacity of the railways. The lack of a sufficiency of coal trucks is still a serious hindrance. Figures have been published this week to show that the loss of trade in the last five or six weeks due to this cause exceeds that of the great strike in May of 1889. Prices are very firm, with an upward tendency in some sorts. Coal consumers are beginning to complain of the high prices which have been arrived at by combinations among the manufacturers. The Bavarian Government, with a view, it is said, of breaking up the "coal ring" or syndicate system recently extended to the whole of the Westphalian district, is getting coal from Bohemia, whence it is obtained much cheaper than from this locality.

AMSTERDAM, 5th January, 1891.

The Weather and Navigation.—The stoppage of all navigation for some considerable period upon the North Sea Canal, owing to the stress of the weather, has caused much inconvenience to the trade and serious losses to traders. Their complaints about what they consider laches upon the part of the Government, by reason of its declining to keep open the waterway at all times and seasons, have found vent in an address to the Burgomaster, signed by all the leading merchants and shippers of Amsterdam. In consequence of these remonstrances the Burgomaster has called a meeting of the principal firms, to debate and decide upon measures to prevent in the future a recurrence of the total closing of the water traffic which was witnessed at the end of last year.

The Railways and the Public.—The acquisition of the Dutch-Rhenish Railway by the State, and the reorganisation of the entire service between the leading companies, have led to much confusion and vexatious delays in various directions. Railway unpunctuality has become a standing scandal. Goods trains are either not despatched at all, or despatched in a way which would not be tolerated even if a strike were in progress. As for passenger trains, they arrive anyhow, which is shown by a striking table published daily by some newspapers, stating the times at which the trains ought to arrive, and the periods at which they make their appearance, as noted down by special reporters. In consequence of this state of affairs a strongly worded address has been sent to the Minister for the Means of Communication by the Chamber of Commerce at Rotterdam, in which the latter asks the pertinent question of what good it is that Rotterdam can be approached at all times by ocean vessels, even in the coldest winter, if goods arrived in them cannot be carried by the railway companies to their destination. The Chamber quotes numerous instances of serious delay, and points to a well-accredited rumour that the managers of the Holland Railway and the State railways had agreed to request the German Railway Department to stop all goods traffic to Holland—a truly humiliating avowal of their incapacity. The Chamber opines that the two named companies are not sufficiently equipped to cope with the increased volume of business as imposed upon them by the new railway law.

The Telephone.—The Dutch Government has declared in the States-General that a Bill for the better regulation of the telephone service is still under consideration. It is in no hurry to present it, because of an evident tendency abroad to make telephones a government monopoly. The Dutch Ministry considers it a wise plan to await further developments before attempting any legislation.

The New Waterway at Rotterdam.—Mr. Dirkzwager has just issued the seventeenth annual edition of his useful, and (to navigators and traders alike) indispensable, English "Guide to the New Waterway, Maassluis, and the Hoek van Holland for 1891." This book contains all necessary information about pilotage, tuggage, dues of various descriptions, and the maximum depths in the navigable channel. From a table of such depths, also indicated upon a special map—one of five excellent and clear charts added to the book—it appears that the draught in the navigable channel, which was only 43 decimetres in 1875, had increased to 50 decimetres in 1881, to 70 decimetres in 1884, to 81 decimetres in 1886, to 88 decimetres in 1889, and to 93 decimetres in 1890, all at high water. Thus the navigable channel has more than doubled its depth since 1875, and the largest ocean steamers can now comfortably approach Rotterdam. Mr. Dirkzwager also shows that Rotterdam for English traders is the nearest, easiest, and cheapest Continental port of any dimension—a fact worth knowing and stating.

Railways.—The Holland Railway Company has commenced a night service for merchandise, for the first time in its history. This is owing to an enormous increase of business.

STOCKHOLM, 3rd January, 1891.

Nickel Mining.—At Ruda a nickel mine has recently been started. As far back as fifty years ago experimental blastings went on in that locality, but no practical results were obtained at the time. The same man has now, however, half a century afterwards, succeeded in forming a company to start the working, and the affair now looks promising. The mine has been sunk to a depth of about 100ft., and a good-sized lot has already been sent to England. Considerable quantities of ore have been found, containing 8 to 10 per cent. nickel, with some intermixture of iron, copper, and other metals.

The Swedish Norwegian Railway Company.—The negotiations between the Swedish Government and the company are still progressing The Government has not accepted the offer of the debenture-holders in its original shape, but has submitted another proposal on nearly the same lines. There can be no reasonable doubt as to the definite result, as the company is virtually at the mercy of the Swedish Government.

The Large Industrial Exhibition at Stockholm in 1893.—This Exhibition is already attracting much attention, and will no doubt prove a very interesting and important affair. A large number of industrial concerns and corporations have given expression to their great interest in the matter, which will probably be proceeded with at an earlier date than was at first contemplated.

Further Purchases of Private Telephone Companies by the State.—The State Telegraph Department has again made an important purchase of a private telephone concern, viz., the large Haglind telephone installation, which embraces forty central stations in the provinces of Ostergötland, Smaland, and Nerike, and has about five hundred subscribers. The State takes over the thing as it stands, keeps on the old staff, and enters into the same

Digitized by Google

obligations as the vendors had. The installation will probably be brought into connection with the large telephonic system of the State telephones, and the State will probably also purchase one or two other private telephone concerns which have been in connection with that of Messrs. Haglind Bros.

Bogie Carriages.—This American type of railway carriages is finding favour in Sweden, and the Stockholm-Vosteros Railway has just ordered six of them.

CHRISTIANIA, 3rd January, 1891.

Sealing and Other Industries.—A number of statistics have already been compiled with reference to various industries in the past year. With regard to sealing, the following particulars may be of interest:—From Tönsberg were despatched eleven steamers, with an aggregate tonnage of 2,748 tons; they brought back altogether 25,876 skins of seals, 5,630 barrels of seal blubber, 353 bottlenoses, 3,700 barrels bottlenose blubber, 24 bears, and 3 walrus; from Moss, one steamer brought back 650 skins of seal, 130 barrels of seal blubber, and 15 bears; from Sandefjord, nine steamers, with a yield of 7,766 skins of seal, 1,455 barrels of seal blubber, 517 bottlenoses, 5,725 barrels bottlenose blubber, and 3 bears; from Arendal, three steamers, with a yield of 14,601 skins of seal, 3,300 barrels of seal blubber, 7 bottlenoses, 100 barrels bottlenose blubber, and 7 bears; from Tromsö, one steamer, with a yield of 841 skins of seal, 196 barrels of seal blubber, and 50 walrus. There were consequently altogether twenty-five steamers engaged in this trade, with a tonnage of 6,342 tons, and hands numbering 1,118 men. The total yield of this industry was consequently about 49,734 skins of seal, 10,705 barrels of seal blubber, 49 bears, 1 norwhale, 53 walrus, 878 bottlenoses, and 9,535 barrels bottlenose blubber. The financial result in this branch of last year's trade cannot be looked upon as satisfactory.

COPENHAGEN, 3rd January, 1891.

The Copenhagen Fire Brigade.—The fire brigade of Copenhagen is about to be considerably enlarged, and its rearrangement has necessitated the acquisition of new plant. A large new central station is in course of erection, and there will also be sufficient accommodation for practice and drill. This station is not expected to be ready till the spring of 1892. The old organisation suffered from various defects, one of them being the fact that none of the officers resided at the stations, so that the first work always had to be done by non-commissioned officers. The basis for the new arrangement is that every point in the town should be reached in ten minutes at the latest from the discovery of the fire, and that a complete extinguishing train should then arrive. The maximum of ten minutes would be used in the following manner:—Three or four for the bringing of the alarm, two for its transmission and for getting ready, and four for reaching the place of fire, calculated at a speed of 800ft. per minute, or rather more than eight miles an hour. According to this arrangement every station is to be the centre of a district with 3,200ft. radius. On the new drill ground will be erected a tower 100ft. high. The force of the fire brigade will, according to the new arrangement, consist of seven officers, twenty-four non-commissioned officers, four machinists, and 160 men, comprising three buglers and twenty-five drivers. The plant will comprise four good-sized steamers with tenders, ten station fire engines (in the meantime, for hand-power), five fire escapes, two carriages, and thirty-four horses.

The Danish Chicory Manufactories.—Amalgamation and co-operation are the order of the day in many Danish industries. The movement has now extended to the manufactories of chicory, delegates from which recently held a meeting in order to bring about some arrangement. Of late years the production has been too great, and an excessive competition has forced the prices down so as not to leave a reasonable profit. It has now been decided to reduce the output and raise the prices. The Eiley manufactory will be discontinued, and will receive compensation. It will be henceforward used only for drying purposes. Only one manufactory, the "Norrejylland," remains outside the arrangement.

MADRID, 5th January, 1891.

Electric Light in Madrid.—The palace of Las Cortes is to be electrically lighted by means of a separate installation, but the lighting of the House of the Senate will be supplied by one of the central stations. Every day some fresh establishments are adopting the use of incandescent lamps, while others which adopted the system a month ago have gone back to the use of gas. This action on the part of customers appears to be justified, as the companies are charging the excessive price of 1s. 3d. per unit, and make their customers pay double or treble the fair price for the fittings. This will probably cause the adoption of small installations with 500 to 1,000 lamps, which will be of a suitable size for the lighting of the blocks of buildings let out in flats.

Improvements of the Harbour at Bilbao.—The corporation, which is entrusted with the improvement works, has issued an important report. Most of the works at the inner port have been completed, and attention can now be devoted almost entirely to the outer port or entrance of the Nervion. The works which have been commenced were contracted for at the sum of £818,000. Up to the date of the report, the 30th June, 1890, the contractors had done little more than organise the work, but rapid progress will now be made. The contractors are two French firms, Messrs. Couvrieux Fils and M. Félix Allard, and the committee and engineers seem perfectly satisfied with the manner in which the work is being carried out. The total receipts of the corporation during the year were about £125,000, and the funds in hand were about £40,000. As eight or nine years will be required for the completion of the works the revenue is quite sufficient for the payment of all expenses, and it will be easy to raise any further amount which may be required, as the credit of the corporation is very good.

Import Duties on Grain, Meat, and Live Animals.—By a Royal decree of the 26th ult. the duties on grain, flour, rice, salted meat, lard, and bacon have been considerably increased, a course for which the Government was authorised by law. The new duties are of a strongly protective character, and were put in force three days after the publication of the decree, those articles alone being excepted which left the port of shipment before the 27th ult. The decree affects the general law according to which reductions were to be made at fixed periods, and all import duties were to be on the basis of a 15 per cent. maximum. While the existing treaties are in force, no alteration can be made, but a commission has been appointed to consider a definitive tariff which is to be adopted on the expiry of all engagements in 1892. The principal articles on which the increase is already in force are—

		Pesetas.	Pesetas.
Cattle—per head,	previous duty	13·80,	now 40
Pigs	" "	8·45 "	40
Salt beef	per 100 kilos, "	2·80 "	11·60
Pork, lard, and bacon	" "	15 "	50
All other meat	" "	5·70 "	18
Wheat	" "	5·70 "	8
Flour	" "	8·25 "	13·20
Other grain	" "	3·10 "	4·40

Should this Government exist until the date of the total revision of the duties, it is to be feared that trade in general will be much inconvenienced.

Sugar Factories.—The erection of factories for the extraction of sugar from beetroot seems to be making progress in Spain. The establishment of a factory at Aranjuez is announced, and there is said to be room for a dozen more factories in this country.

NEW YORK, 27th December, 1890.

The Coal Trade.—The demand for anthracite has increased in consequence of the colder weather, and the retailers are doing a good business. Steam sizes are in demand and scarce. Prices are not very well maintained. There is considerable interest in the next meeting of the representatives of the trade, as it is expected that they will allot for the month of January not less than 3,000,000 tons, on the expectation that there will be a large increase in tonnage during the coming year.

The Tinplate Industry.—The preparation for the manufacture of tinplate in this country is progressing rapidly, and the first of the year will see several large plants in process of construction. The latest is being erected at Cleveland, Ohio. Mr. Britton, of the Britton Iron and Steel Company, of that city, having disposed of his interest in that concern, has purchased a tract of eleven acres of land on the Lake Shore and Michigan Southern Railway, running 1,000ft. north of Lake Erie. They have already under cover a building 160ft. by 130ft., in which there is a plate and sheet mill, which will be in operation by the 1st January, 1891, and are preparing to erect other buildings in which the mills will be used for the production of galvanised sheet and tinplate. It is expected that the mills will be able to put tinplates on the market by the 1st of July. Mills have also been projected and contracts signed for the machinery and equipments for tinned plate mills for St. Louis, Chicago, and Demier and Apollo, Pa., and plans and estimates are being considered for several concerns situated near the iron centres.

Nickel Steel.—The first attempt to produce nickel steel was made recently at the Homestead Steel Works, near Pittsburgh. The experiment was made with a five-ton "heat" in a Bessemer converter. Part of this steel was rolled into ¾in. plates, from which specimens were tested. In two samples the elastic limit was 59,000lb. and 60,000lb., and the breaking resistance 100,000lb. and 102,000lb. The elongation was 15¼ per cent. in each specimen, and the reduction in area 29¼ and 26½ per cent. The steel contained 3·16 per cent. of nickel. Within the next ninety days this firm expects to deliver to the Navy Department their first armour plates, of which some will be all steel and the rest nickel steel.

A Large Failure.—The Lorillard Brick Works Company, of New York and Keyport, N.J., has been placed in the hands of a receiver. The company had in its possession about $200,000 of real estate and builders' paper, and was short of ready cash. Their works at Keyport are said to be the most complete in the United States. Their property include 270 acres of clay-bearing land and buildings covering eight acres fully equipped with labour-saving machinery. The liabilities of the company will amount to upwards of a million dollars, but the assets are enough to fully meet all the debts and leave a considerable balance.

Failure of a Steel Firm.—A receiver has been appointed for the Henderson Steel Company, of Birmingham, Ala. The liabilities are $23,000, while the assets are appraised at $85,000. The company lost $12,000 by the recent failure of the Bessemer Rolling Mill Company, as the latter company had contracted for the entire output of the steel company for twelve months. The Henderson Company had after much experimenting succeeded in making steel from the phosphorus-bearing ores of the district by a new basic process, and were about to increase their plant and put up a rail mill, when the receiver was appointed.

PHILADELPHIA, 26th December, 1890.

Railroad Contest.—A sharp fight is looked for between the Pennsylvania Railroad and the Baltimore and Ohio and the Western Maryland Railroads, concerning the extension of the last-named road to connect with the Baltimore and Ohio at Cherry Run. The Pennsylvania has secured a charter to construct a road from Shippensburg, on the Cumberland Valley road, to a point on the Bedford division of the Pennsylvania near Mount Dallas. This road will be sixty miles long, and has a capital stock of $2,500,000. By the alliance of the Baltimore and Ohio, Reading, and Western Maryland roads, the Reading Company obtains a western outlet, and is nearer the bituminous fields. The Pennsylvania hopes to neutralise the benefit derived from this alliance by securing to itself the traffic of the coal regions, as it now delivers most of its soft coal traffic into the hands of the Reading Railroad, thus enabling the latter company to make large profits out of Pennsylvania tonnage.

The Issue of Patents.—The Attorney-General has given an opinion which will have an important effect on the issue of patents. The practice of inventors has been to indefinitely postpone the taking out of letters patent by neglecting to pay the final fees within the required six months, and then, before the expiration of the two years allowed by law, to apply to have the application renewed. This process in some cases has been repeated for many years, thus materially extending the life of the patent beyond the seventeen years specified in the statutes. The Attorney-General holds that a patent cannot be allowed on an application for renewal if such application is not filed within two years after the allowance of the original application.

Forts and Great Guns.—The Fortification Appropriation Bill for the next fiscal year will carry an aggregate appropriation of $4,498,803, or $3,005,520 less than the estimates. The principal items are—Torpedoes for harbour defence, $216,000; gun and mortar batteries, $1,000,000, for the defence of Boston, New York, San Francisco, Hampton Roads, and Washington; sites for fortifications, $500,000; armament for fortifications, $1,790,460, of which $1,000,000 is for forgings for the Waterwhet Gun Factory; for completing buildings and plant at the gun factory, $750,343; and for tests and experiments, $100,000. The total capacity of the gun factory when completed will be twelve 8in., fourteen 10in., and twenty 12in. guns per year.

Naval Vessels.—The "Newark" went out again on the 20th inst. for its trial under Government auspices. Two attempts had already been made, but the breaking of a pin in the valve gear has on both occasions postponed the trial. Tenders were opened on the 20th inst. at the Navy Department for the construction of a harbour defence ram, and the torpedo boat "Number Two," similar to the "Cushing."

Rapid Transit.—As the time for election of members of city councils draws near there is considerable activity about the question of rapid transit. The Reading Railroad has for a long time been trying to obtain permission to carry its lines into the centre of the city, and under the pressure of the next election an ordinance has been passed to permit the proposed road. Better facilities are essential if the Reading Railroad proposes to occupy a first place in the scheme of rapid transit, and it serves a very large territory, which in a few years would become thickly settled if proper transportation facilities were provided. During the construction of the terminal and other stations there is not likely to be very much paid to holders of its non-obligatory securities, as large sums will be required to carry on the work of construction. The Belt Line Road is also likely to become a reality, as the ordinance has been passed by councils and is now in the Mayor's hands. This will give excellent facilities for reaching the wharves from any of the roads now entering the city, and will add largely to the rapidity with which freight in transit can be handled. The great need of rapid transit in reaching the residential portions of the city is likely to be met in a very short time by the construction of an elevated road from Market Street Ferry on the Delaware River westward to the county line, with branches running north and south. The formation of a committee of fifty of the most prominent citizens to oppose the re-election of those members of councils who are against rapid transit has had much to do with the probable satisfactory outcome of the question.

General Strike Threatened.—A general strike of the switchmen, firemen, and trainmen in the neighbourhood of Pittsburgh is threatened. A demand has been made for a reduction in hours from twelve to eight hours a day and an advance in wages of 15 per cent. The officials of the Pennsylvania, Baltimore, and Ohio and Lake Erie lines are considering the demands, but no answer has yet been made.

THE "UNIVERSAL" EMERY GRINDING MACHINE.

CONSTRUCTED BY THE BROWN & SHARPE MANUFACTURING COMPANY, PROVIDENCE, RHODE ISLAND, U.S.A.

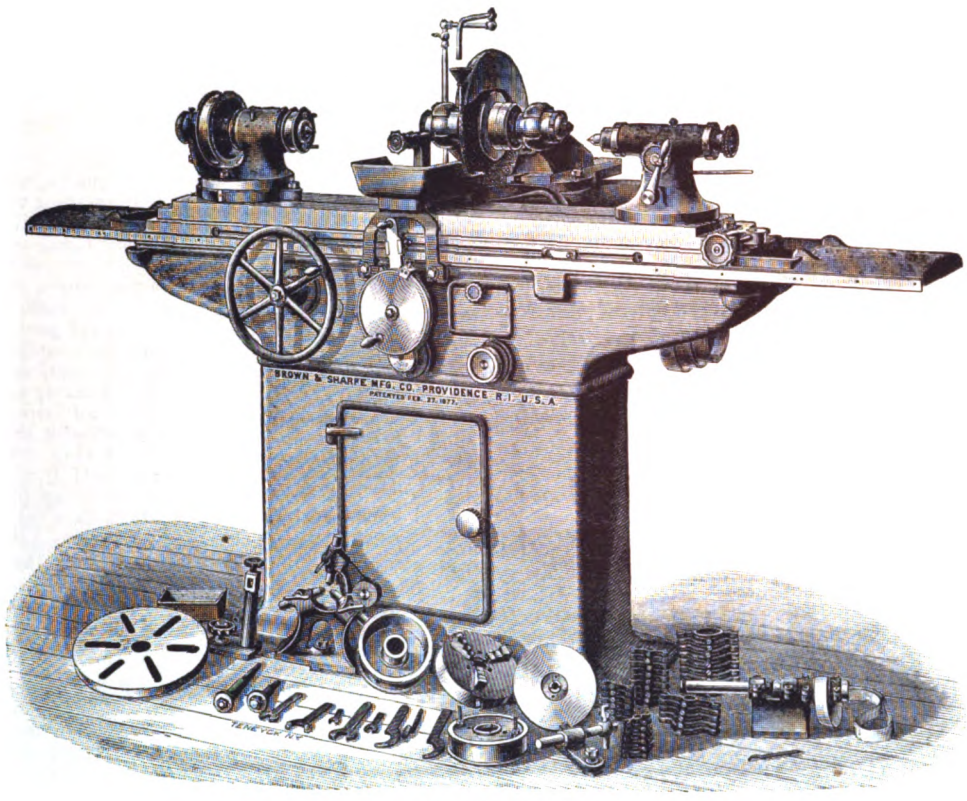

FIG. 1.—FRONT VIEW.

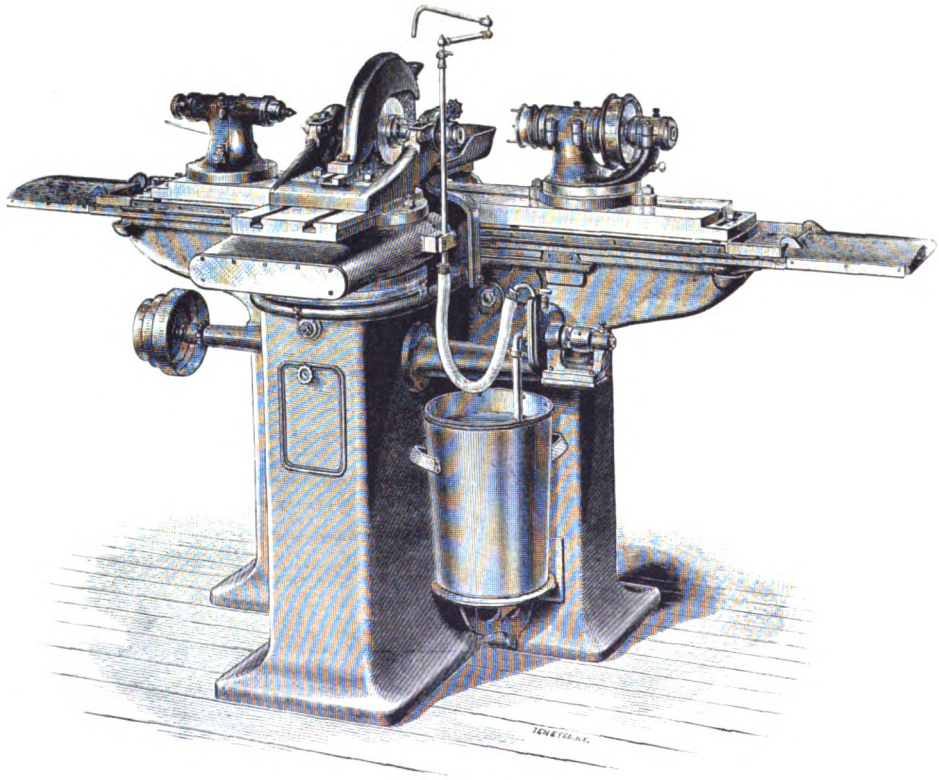

FIG. 2.—REAR VIEW.

THE "UNIVERSAL" EMERY GRINDING MACHINE.

THE above engravings, Figs. 1 and 2, represent a front and rear view respectively of a very useful emery grinding machine, capable of treating both parallel and taper, and external and internal surfaces. The accuracy and uniformity of the work produced are rarely approached by this class of machinery. It is made by the Brown & Sharpe Manufacturing Company, of Providence, Rhode Island, U.S.A., whose reputation on both sides of the Atlantic is a sufficient guarantee for the excellence of their workmanship. The machine which we illustrate is extremely rigid, and has large bearing surfaces, improved reversing mechanism, and a transverse feed capable of delicate adjustment. The feed gearing is enclosed in the bed, and dust caps protect the spindle bearings of the head and foot stocks and wheel carriage from particles of dust. In order to allow the grinding of taper bodies without throwing the head and foot stock spindles out of line, a swivel table with automatic and hand-feed mechanism is provided, which turns on a centre pin on the sliding table, while a graduated scale shows at a glance the amount of taper imparted to the body in degrees and inches per foot. The foot-stock spindle is adjustable by means of a lever, and a spring is provided to allow for expansion through heat produced by friction of articles being ground. The machine illustrated will accommodate between the centres work 12in. diameter and 30in. long, and is provided complete with all the necessary tools and overhead gear.

SHIPBUILDING IN THE ROYAL DOCKYARDS DURING 1890.

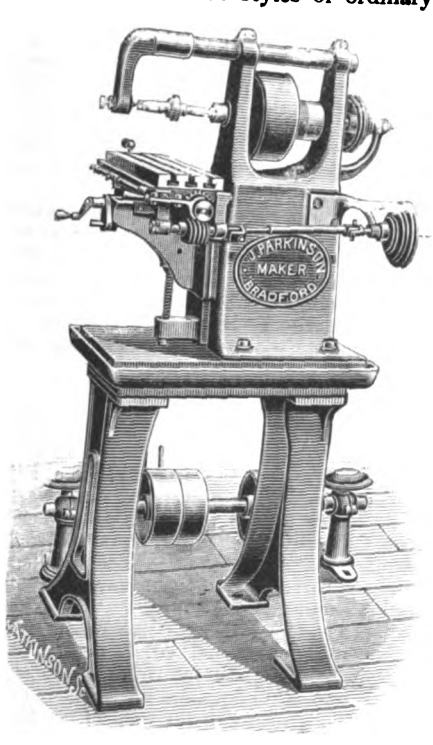
THE extent of the tonnage launched from the Royal Dockyards during the past year is small. If, however, the original programme, as laid down by the authorities at Whitehall, could have been adhered to, the output would have been materially increased. The "Centaur," first-class cruiser, which was intended to have been launched at Portsmouth in November last, will not now be put into the water till next month, and the "Hawke," a similar vessel on the stocks at Chatham, which has been practically ready for launching for some time, will not now leave her berth till well on in this year. The launching ceremony of the second-class deck-protected cruiser "Apollo," built at the last-mentioned establishment, has also been deferred. As it is, only eight vessels, having an aggregate tonnage of 22,520 tons, were added to the navy from the five Royal Dockyards. Of this number Devonport contributed three, one first-class cruiser and two second-class cruisers; Sheerness, two torpedo gunboats; while Chatham, Portsmouth, and Pembroke each contributed a second-class cruiser. The "Edgar" is by far the largest and most powerfully armed of these additions to the navy, and is the first of a special type of first-class protected cruisers which are being built under the Naval Defence Act. She is 360ft. in length, 60ft. in extreme breadth, with a mean draught of water of 23ft. 9in., the normal displacement being 7,350 tons. The engines, which are of the vertical triple-expansion type, have been supplied by the Fairfield Shipbuilding and Engineering Company, and are capable of developing 12,000 h.p. with forced draught, and 7,500 h.p. with natural draught, which is estimated to realise sea speeds of 18 knots and 20 knots respectively. The "Edgar" was laid down in June, 1889, and launched on November 24th, up to which date fully 2,800 tons of material had been worked into her structure. She is the largest vessel ever launched from Devonport Dockyard, and has been built at a cost of £327,000.

Next in point of tonnage is the fast cruiser "Andromache," which was launched at Chatham on August 14th. Her first keel plate was laid in May, 1889, and before leaving the slipway not less than 1,300 tons of her substance had been fixed in position. She measures 300ft. between perpendiculars, 43ft. in extreme breadth, and will have a displacement, when fully equipped, of 3,431 tons on a mean draught of water of 16ft. 6in. The engines, which are of the triple-expansion type, have been constructed by Messrs. Earle & Co., Hull, and are estimated to develop 9,000 horse-power under forced draught, and to give the vessel a speed of 20 knots. The "Andromache" has been built of steel throughout, with a protective deck of a minimum thickness of 2in., and a maximum thickness of 5in. over the engine hatch, at a cost of about £179,100.

The second-class protected cruiser "Pallas," which was laid down on July 1st, 1889, was floated out of No. 4 Dock at Portsmouth on June 30th. On the following day a sister vessel, the "Phœbe," was launched at Devonport, while the "Pearl" and "Philomel," two other vessels of the same class, left their berths at Pembroke and Devonport respectively, the former on July 28th, and the latter on August 28th last. Each of these vessels has a length of 260ft. between perpendiculars, a breadth of 41ft., and a load displacement of 2,575 tons on a mean draught of 15ft. 6in. They are built of steel throughout, and fitted with a protective deck running right fore and aft, the thickness in wake of machinery spaces ranging from 1½in. to 2in., and varying at the extremities from ¾in. to 1in. Their propelling machinery consists of two sets of triple-expansion engines, the estimated horse-power being 7,500 under forced draught, and 4,500 under natural draught, the resulting speeds being estimated at 19 knots and 16½ knots respectively. In these vessels the normal displacement is made up roughly as follows:—Weight of hull, 1,030 tons; weight of engines, 540 tons; weight of stores, armament and equipment, 705 tons; and coal capacity 300 tons, a quantity estimated to ensure the vessel covering a distance of 4,800 knots at a 10-knot

Digitized by Google

speed. The "Pearl" and "Philomel" have been engined by Messrs. Earle & Co., Hull; the "Pallas," by Messrs. Hawthorn, Leslie, & Co., Newcastle-on-Tyne; while the machinery of the "Phœbe" has been constructed by the Government employés at Devonport. The average total cost of these vessels is about £142,000.



The other two ships included in last year's output are the "Gossamer" and "Gleaner," which were commenced at Sheerness Dockyard on January 21st, 1889, and launched on January 9th, 1890. They are built on similar lines and of similar scantlings to the "Sharpshooter," and are officially designated first-class torpedo gunboats. They are 230ft. in length between perpendiculars, 27ft. in extreme breadth, and have a displacement of 735 tons on a draught of water of 8ft. 3in. They are provided with machinery of a powerful character, the estimated horse-power being 4,500 under forced draught, and 2,500 with natural draught, while the speeds expected are 21 knots and 18·5 knots respectively. The engines are of the triple-expansion type, designed by the Admiralty engineering staff, and constructed in the engine department at Sheerness Dockyard. The average cost of these vessels is £54,450. The "Gossamer" is at present awaiting her trials at Sheerness, and special interest will attach to them, as her engines are the first constructed in the Sheerness establishment, the machinery of all previous vessels built at the yard having been supplied by contract.

SUMMARY OF LAUNCHES.

Name.	Displacement.	H.P.	Where Built.	Engined by
"Edgar"	7,350	12,000	Devonport	Fairfield Co.
"Phœbe"	2,575	7,500	Devonport	Admiralty.
"Philomel"	2,575	7,500	Devonport	Earle & Co.
"Pallas"	2,575	7,500	Portsmouth	Hawthorn, Leslie, & Co.
"Pearl"	2,575	7,500	Pembroke	Earle & Co.
"Andromache"..	3,431	9,000	Chatham	Earle & Co.
"Gossamer" ...	735	4,500	Sheerness	Admiralty.
"Gleaner"	735	4,500	Sheerness	Admiralty.

A MINIATURE MILLING MACHINE.

THE illustration below represents a small milling machine as constructed by Mr. J. Parkinson, machinist, Bradford. It has been devised for dealing with light work, and it is claimed for it that it is easier to manipulate and capable of yielding a greater output than a larger machine. It is fitted so as to fulfil all the requirements of the various styles of ordinary milling.

Its capacity may be seen from the following dimensions: The table has an automatic horizontal longitudinal travel of 11in., a transverse horizontal travel of 3½in., and a vertical travel of 6in. The automatic travel arrangement will move the top slide in any position, and is provided with a regulating feed stop to throw the feed out of gear when desired. The general appearance of the machine is neat, and the parts well designed.

WE have received from Messrs. Atkinson & Philipson Northumberland Carriage Manufactory, Newcastle-on-Tyne, a revised edition of their "Rules for the Preservation of Carriages and Harness." The rules are printed upon stout highly glazed cardboard, suitable for hanging in coach-houses, harness-rooms, &c., and contain some very useful hints.

Notices of Meetings.

THIS WEEK.

MANCHESTER ASSOCIATION OF ENGINEERS.—Saturday, January 10th, at 7 p.m. Presidential Address by Mr. John West, M.Inst.C.E.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Saturday, January 10th, at 6 p.m. Paper to be read: "Mechanical Aid to the Investigation of Experimental Curves," by Mr. J. D. Young. Discussion on Mr. Hök's paper on "The Unsinkability of Cargo-Carrying Steamers," and on Mr. Cummins' paper on "Increased Boiler Pressure and Increased Piston Speed for Marine Engines."

SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS MANAGERS.—Saturday, January 10th, at 7 p.m. Paper to be read: "The Round Oak Iron and Steel Works," by Mr. R. Smith-Casson.

SHEFFIELD SOCIETY OF ENGINEERS.—Saturday, January 10th, at 7.30 p.m. Lecture on "The Microscopic Analysis of Iron and Steel," by Dr. Clifton Sorby, F.R.S.

NEXT WEEK.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday, January 12th, at 8 p.m. Sessional meeting. Announcement of award of prizes.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, January 13th, at 8 p.m. Ordinary meeting. Paper to be read: "Auxiliary Engines in Connection with the Modern Marine Engine," by Mr. W. H. Allen, A.M.Inst.C.E. Monthly ballot for members, and, at 9 p.m., the first of a series of monthly receptions.

SOCIETY OF ARCHITECTS.—Tuesday, January 13th, at 7.30 p.m. Ordinary meeting.

SOCIETY OF ARTS.—Wednesday, January 14th, at 8 p.m. Paper to be read: "Steam Lifeboats," by Mr. J. F. Green.

INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, January 15th. Presidential Address by Mr. W. Crookes, F.R.S.

DUNDEE INSTITUTE OF ARCHITECTURE, SCIENCE, AND ART.—Thursday, January 15th, at 8 p.m. Lecture on "Some Architectural and Other Notes on Portugal and Spain," by Mr. Campbell Douglas.

PRICES CURRENT, 7TH JANUARY, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER continues inactive, small business taking place. Owing to the slack demand values of raw copper are receding, Chili bars being quoted to-day £52 5s. to £52 12s. 6d. cash, with flat market.

Stocks increased about 1,480 tons during the second fortnight in December, the total stock at December 31, 1890, being returned as about 65,360 tons. Manufactured quoted £66 to £67, "strong."

TIN has improved somewhat during the week, values of foreign having advanced about £1 per ton.

LEAD: Quiet, without change in values.

SPELTER continues very stagnant, the galvanising trade being very slack and demand altogether small.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Business is resumed but slowly after the holidays, and there is little of interest to report. Carbolic acids, crude and crystal, are very dull, but prices are about stationary; liquid carbolic is, however, in better tone. Sulphate of copper also is quiet, sales being small and mostly of second-hand parcels Copperas is still in demand, and prices tending further upwards Lime salts are steady, but only small business doing. There is more disposition to purchase sulphate of ammonia, but buyers do not see their way to the higher prices that are asked, this spurt being caused by the reports of a possible combination amongst nitrate of soda producers.

HOME INDUSTRIES.

LONDON, 8th January, 1891.

The Money Market.—The release of the Government dividends on Monday has flooded the market with money, for which there is scarcely any demand, and rates have given way completely. The apprehension that the issue of the new French loan on Saturday would disturb the money market has been allayed, and with considerable arrivals of gold at the Bank there seems every prospect of a long period of cheap money. The stock markets have been idle and dull all the week. The growing cheapness of money has produced an improvement in Consols and gilt-edged securities, but it has not extended to other departments. Operators in home railways are inclined to pause until the declaration of the earlier dividends, the first of which are due at the beginning of next week, give an idea of the extent to which the increased working cost during the half-year has affected net earnings. The prolongation of the strike in Scotland has also an adverse effect. Americans, though distinctly disposed to improve, hang back, and move in rather a feverish way. Foreign securities have been steady, with few changes, though the Paris market was weakened by a rather trying settlement, at which money rates were high. In the miscellaneous departments there has been no general feature, but there has been a good deal of activity in some of the minor speculative specialties, owing to the collape of several extensive operators.

Traffic Receipts.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 28th December amounted, on 16,244¾ miles, to £1,218,288, and for the corresponding period of 1889, on 16,146 miles, to £1,255,179, an increase of 98¾ miles, or 0·6 per cent., and a decrease of £36,890, or 2·9 per cent.

Great Northern Telegraph Company.—The traffic returns give the receipts in December, 1890, as £23,600. The receipts from 1st January to 31st December, 1890, were £280,000, those for the year 1889 being £274,800, and for the year 1888 £272,200.

Institution of Mechanical Engineers.—The annual general meeting of this Institution will be held at 25, Great George Street, Westminster, on the 29th and 30th inst., at 7.30 p.m., the President, Mr. Joseph Tomlinson, being in the chair. On the 29th inst. the annual report of the Council will be presented to the meeting, and the annual election of the president, vice-presidents, and members of council will take place. The following papers will then be read and discussed :—"On some Different Forms of Gas Furnaces," by Mr. Bernard Dawson; "On the Mechanical Treatment of Moulding Sand," by Mr. Walter Bagshaw; and the "Fourth Report of the Research Committee on Friction: Experiments on the Friction of a Pivot Bearing."

The Metropolitan Outer Circle Railway Company.—This company, which was formed in the year 1888, with a share capital of £1,600,000, has two Bills in Parliament, the first of which asks for an extension of time for purchasing land until August, 1894, and for the completion of the line until August, 1896. The second Bill relates to a line which would connect all the trunk railways in London by means of a railway, over eighteen miles in length, from the Great Western and Metropolitan District Railways at Ealing, passing through Kingsbury, Hendon, Finchley, and Colney Hatch, to the Great Eastern Railway at Tottenham. According to the preamble of the Bill, no part of the capital has been created or issued, and permissive powers to abandon the scheme are asked for.

Proposed Electric Railway.—A Bill for the construction of an electric railway between South Kensington and Paddington has again been deposited in the House of Commons. The measure, which was introduced last Session, and afterwards withdrawn, has since been somewhat modified. According to the present scheme the line will be about 1¾ miles long. One terminus will be near the Exhibition Road, Kensington, and the other near the Bishop's Road bridge of the Great Western Railway. The capital of the company will be £276,000, with power to raise a further sum of £92,000.

The Strike of Post Office Clerks.—It is stated that the Postmaster-General will grant an interview to-day to the Post Office clerks in response to their application, which was suggested by Sir Arthur Blackwood on the 5th inst. At this season of the year, when the pressure of work is great, the clerks are expected to work overtime, but at ordinary times permission to work overtime is applied for voluntarily by the men.

Stanger's Laboratory and Testing Works.—Mr. W. H. Stanger and Mr. Bertram Blount, of the Broadway Laboratory Testing Works, Westminster, desire to correct a rumour which has become prevalent, by stating that the Mr. William Fox, who is at present associated with them at the above address, is a Member of the Institution of Civil Engineers and not a practising analyst.

Price List.—Messrs. G. Bailey Toms & Co., of 7A, Laurence Pountney Hill, London, E.C., have issued a well-illustrated and very complete revised price list of their productions, which include portable railway plant, locomotives, rolling stock, cast-iron pipes, columns, &c. There is also a complete list of 2,000 sizes of iron and steel joists, channels, angles, tees, and fancy sections, rolled and kept in stock.

Diaries.—We have received from Messrs. Appleton, Burbey, & Williamson, 91, Queen Victoria Street, London, E.C., specimens of a new form of perpetual diary, which is made in porcelain, and, being combined with a tablet for memoranda, seems especially well suited for its purpose.

MANCHESTER, 8th January, 1891.

The Ship Canal.—The greater part of the various sections of this work, which were flooded a few weeks ago, have now been practically cleared of water. The chief delay from this cause took place in the masonry and concrete work connected with the aqueduct at Barton and the various locks. The work, however, has for some time been resumed, and the water is being rapidly pumped out of all the cuttings. The rate of pumping can be estimated when it is stated that in one section, 3¼ miles in length, the level was reduced at the rate of 2ft. per day. This implies an immense volume of water, and shows that the same resource is being exhibited by the contractor as in the Severn Tunnel, where a good deal of this work had to be done. Owing to the exceptional weather, the works between the Weaver estuary and Eastham have been somewhat delayed, and the opening of that section will not take place for a few months. As an instance of the probabilities of local traffic arising, a specially constructed steamer has been launched at Belfast, designed for the direct Manchester and Belfast traffic. Until the opening of the canal she will ply to Liverpool.

The Engineering Trades.—The holidays in this district are so protracted that it is difficult to form an opinion as to the state of trade or its prospects. So far as can be judged, however, there is not so much doing as there has been. There is a certain dulness in business, which, although it may be only temporary, is somewhat strange. At the same time, there is plenty of work in hand, and probably by the time this is exhausted new orders will be in the market. Generally engine builders, boiler makers, and millwrights are well occupied, and the same remark applies to machine tool makers, who, as yet, do not experience any falling off in orders. In spinning machinery there is still a brisk demand, and it is computed that the mere supply of the machines necessary for replacements is sufficient to keep the existing works well occupied. In all, about 4,000,000 spindles per year, with the preparation machinery, is wanted, on an average, for renewals, and this quantity closely approaches the productive capacity of existing works. There is work enough in hand now to last several months, and no uneasiness exists in this department as to the immediate future. The loom trade continues to be steady, without any pressure existing, and there is also a fair amount of work in the ironfounding business.

The Linen and Jute Trades.—There has not been much business done this week. Stocks, it is understood, are not heavy amongst the small dealers, and there will most probably soon be a revival in the trade. One wholesale concern has already held its first special sale, and in a short time others will follow suit with a view of giving an impetus to the market. Prices in the low Irish end are decidedly firmer, even roughs occupying a stronger position. The last-named goods are not appreciably higher in the lower numbers, but in the higher ranges the position is more clearly defined, and there is no disposition to make any concessions to buyers, who, in fact, are willing enough to purchase at old prices. Where customers refuse to take the range, sellers ask higher prices for the low numbers. There is nothing fresh to report concerning the linen thread trade, except that one of the leading agents in the business has transferred his services to Messrs. Ainsworth, of Cleator, and will undertake the control of their London home trade and shipping business. The rumoured combination between Barbours and Finlaysons (the largest firms in the business) has not been confirmed. Much inconvenience continues to be caused by the Scotch strike, many consignments of goods for this city having been seriously delayed. In the case of Dundee products the goods are being sent through the Caledonian Canal to Glasgow, and thence by sea to Liverpool, or are transported to an East Coast point, whence they reach Manchester by rail. Jute goods are quiet. Wholesale houses make no change in quotations, although they themselves are constantly being affected by the fluctuations in the price of raw material.

Brewers and the Water Supply.—An interesting point has been raised in Oldham with reference to the supply of water for brewing purposes. The reservoirs from which the town of Oldham is supplied with water are situated in different valleys, and, although the water in each case is fairly pure, there is a little difference in the chemical composition of the salts in solution. It is the practice to change the source of supply periodically, and the brewers of the town complain that when this is done without notice the quality of the brewing is changed. It was remarked by the Town Clerk that brewing was now a chemical process, and that the change of supply from one source to another entailed a good deal of trouble. It was finally agreed by the Town Council that, if possible, a day or two's notice should be given when it was intended to change the supply.

GLASGOW, 8th January, 1891.

The Railway Strike.—The strike, in spite of the assertions to the contrary in most of the daily papers, shows no sign of collapsing. The passenger service on the various lines is being conducted with comparative regularity, though with many mishaps, and not without serious risk. The places of a large number of the men on strike have been filled by inexperienced men who have neither the skill nor the knowledge to work the lines properly. New signalmen do not understand their duties, and new engine drivers do not know the road. The situation is altogether full of peril. Meanwhile the men are confident, and hold fairly well together. They allege that in spite of the defection of the Glasgow and South-Western Railway men, they still number upwards of 8,000 strikers. Their hopes during the past few days have been concentrated upon the expectation that the railway companies, barely able to cope with the passenger traffic during the holidays, would be quite unable to deal with the goods and mineral traffic when the works, especially in the western district, resumed this week. This expectation has undoubtedly been largely justified. The public works in the Glasgow district are practically still closed, notices being posted on the gates that, owing to want of coal, the machinery cannot be set in motion. Although the railway companies have been doing their utmost to cope with the traffic, they have been utterly unable to do more than deal with a small part of it. The evictions of railway strikers from houses belonging to the Caledonian Railway Company at Motherwell doubtless mark a distinct phase in the struggle. Although the agents of the company, with the support of a large body of police, succeeded in evicting some dozen tenants without any actual resistance being offered to the legal proceedings, the town and district of Motherwell were in a state of ferment. The Riot Act was read, and the people were charged repeatedly by the police. The roof of the railway station and two signal boxes were damaged, the whole of the glass and all the lamps being broken. Negotiations promoted by shareholders and by large traders have been taking place with the railway officials on the one hand, and with the leaders of the men on the other; but no prospect of bringing these together has yet appeared. Mr. John Walker, manager of the North British Railway, who is generally regarded as the most considerate man among the administrators of the Scottish railways, had, it was rumoured, resigned. This rumour led on Monday to a rapid fall in North British Railway stock. Since the first symptoms of the strike appeared this stock has suffered heavily. A week prior to the strike it stood at about 56, now it stands at between 49 and 50, a fall of between 12 per cent. and 14 per cent. The shareholders are undoubtedly getting alarmed, the fall on Monday having been 37s. 6d. Meetings of the directors have been held this week, and a meeting of the shareholders of the North British Railway is also said to be contemplated. The trades unions generally are supporting the strike, and the men are in no want of money. The issue before the country and the railway companies is, therefore, very serious, and must be dealt with in a much more statesmanlike spirit than has as yet been manifested by the railway boards. The situation promises to be still further complicated by a strike of the carters in Glasgow. A considerable amount of the inconvenience due to the stoppage of goods transit by railway has been modified by the fact that horse traction was still available. Contractors, indeed, have been extremely busy, and goods have been carted long distances—even thirty miles—for shipment at Glasgow. If the carters also should strike, the general public will be still more inconvenienced.

Engineering.—A meeting of the shareholders of Messrs. Goodwins, Jardine, & Co., Limited, was held at Glasgow recently, under the presidency of Sir Edward J. Reed, the chairman of the company. It was decided that a committee of the shareholders be empowered to confer with the directors as to the present position of the company and the reconstruction of the board. Pending the report of this committee, the directors are empowered to close the Coats works temporarily, and to continue the Motherwell and Ardrossan works.—It is reported that Mr. Walter Neilson, Clydebridge Steel Works, has discovered a method of making steel castings direct from the cupola furnace.

La Plateuse Flotilla Company.—The adjourned meeting of the shareholders of this company was held on the 6th inst., when it was resolved that application be made to the Court of Session for liquidation, subject to supervision of the Court, with the understanding that if a substantial improvement in Argentine affairs took place the liquidation should be suspended.

Coal Supply.—The railway strike has overshadowed everything in the district. There is no coal to be had except at prices which are prohibitive. The whole of the industries in the West of Scotland are seriously hampered, if not altogether paralysed, by the want of raw material on the one hand, and by the impossibility of conveying away finished material on the other.

(From our own Correspondents.)

LIVERPOOL, 7th January, 1891.

The Timber Trade.—The imports during the past month have been moderate, and, as the deliveries have been seriously interfered with by the recent severe weather, the stocks are not so heavy as they appear to be, for large portions are already sold, and are only awaiting the advent of fine weather for delivery. There is very little change in values. The delivery of yellow pine from Canada has been small, and the stocks are ample; sales of square pine have been at low prices, and there is no improvement in waney. The stock of red pine is ample, and there are few inquiries

Digitized by Google

even at the present low prices. The stock of pine deals is too heavy, the imports having been large. There have been no imports of Quebec spruce, and the stocks are excessive. The stock of New Brunswick and Nova Scotia spruce deals is very heavy, although the imports have been light—the consumption has been small and the prices exceptionally low. The stock of pitch pine is still excessive; the consumption has been small, and there have been no imports of hewn timber. The consumption of sawn timber has been fair, and stocks are reduced, as there have been practically no imports.

SHEFFIELD, 7th January, 1891.

Iron and Steel.—The usual Christmas holidays at the iron and steel works here have this year been much curtailed, and all the works have shut down only for necessary repairs. The demand for iron and steel in the ingot and as a finished product promises to be sustained. The success of Messrs. Vickers' all-steel armour plates, which were tested for the Russian Government, has resulted in that firm receiving an order for the belt plates of two gunboats, the "Gremyastchy" and "Otvagny." It will be remembered that the plates tested were so elastic as to throw back with considerable force the shot fired at them. Although Sheffield has lost the chance of supplying armour for the United States navy, the district is indirectly benefiting by its manufacture in America. The contractors have been obliged to employ Sheffield men to show them how the steel was to be made and rolled. Having guaranteed to deliver 6,000 tons in a given time they find it impossible to machine the plates, and have now under construction in Leeds massive planers for this purpose. Some idea of the massive proportions of these machines may be gathered from the fact that the moving table alone weighs over 20 tons. In the manufacture of guns Sheffield is likely to have a formidable competitor shortly in Messrs. Palmer, of Jarrow-on-Tyne, who are now erecting the necessary plant and machinery for this purpose. The demand for steel castings has fallen off considerably during the last month or two. This is more particularly the case with marine work; small castings for hydraulic cylinders, locomotives, and colliery purposes are in fair request.

Coal.—The coal market is exceptionally brisk all round, and great efforts have been made to induce the miners to commence work again after a short stoppage for repairs to winding tackle.

Pictet Ice-making Plant.—Messrs. Baxters, Limited, Sandiacre, near Nottingham, are now busily engaged in laying down new machinery for the manufacture of the Pictet ice-making plant, of which they are the sole licensees for the United Kingdom and Colonies.

NORTH STAFFORDSHIRE, 7th January, 1891.

The Iron Trade.—There is no improvement to report in connection with demand or prices, and some anxiety is felt as to the results of the quarterly meetings this week. Ironmasters are not hopeful as to the immediate prospects of trade, and, on comparing present prices with those of twelve months ago, and taking into account that the cost of production has materially increased in the interim, there is little to encourage them. Bars, which were then over £8 per ton, are now selling at about £6 to £6 5s. Pig iron has fallen £1 per ton, and other prices in proportion. There is nothing in the great consuming industries to warrant a belief in any considerable increase of demand, and no immediate prospect of cheapening the cost of producing the raw material.

The Coal Trade.—Owing to the abnormal severity of the weather, there has been a large demand for coal for household purposes at remunerative rates, and colliery proprietors have been unable to supply their customers' requirements. In many cases this is not for want of "working face" in the pits, but from the irregularity in the attendance of the workmen.

The Pottery Trade.—Correspondence between the operatives and the Manufacturers' Association as to the selection of arbitrators continues, but no settlement has at present been arrived at.

CARDIFF, 7th January, 1891.

Iron and Steel.—The pig iron trade is dull, notwithstanding the depletion of stocks in Scotland. Steel rails find a small market, but Bessemer tinplate bars are active at £5 15s. to £6 per ton. In the iron ore trade a few small contracts have been made for delivery in this channel, but buyers are not so eager to make large contracts as they were last year. Nevertheless, good ore is exceedingly difficult to obtain, and those mine owners in Bilbao and elsewhere who have reliable ore to dispose of find no difficulty in disposing of their output. Rubio ore is quoted at 14s. 3d. to 14s. 6d. c.i.f. Cardiff and Newport, 14s. 9d. Swansea, 15s. Porthcawl, 15s. Britonferry, 15s. 3d. Port Talbot, on the basis of 50 per cent. iron as received. Freights from the ore ports are low, but as owners are laying up a proportion of their tonnage the tendency is upwards.

Coal and Coke.—The steam coal trade has resumed its accustomed activity after the holidays. The present engagements of colliery owners are sufficient to keep them going for the next two months, even if no orders should come to hand in the meantime. Second and third class qualities have advanced relatively more than first-class, which can be accounted for by the economy of buyers. Prices are somewhat irregular, as each colliery proprietor is guided by his own engagements in making quotations, but the following will indicate the figures at which business has been concluded during the week:—No. 1 quality, 15s. 6d. to 15s. 9d.; No. 2 quality, 14s. 9d. to 15s. 3d.; No. 3 quality, 14s. 3d. to 14s. 6d.; No. 4 quality, 13s. to 13s. 9d. The demand for household coal is exceptionally strong, prices for best ranging from 15s. 6d. to 16s.; ordinary, 15s.; and No. 2 Rhondda, 13s. 9d. to 14s. 3d. Coke finds a better market, prices being 19s. 6d. to 20s. 6d. furnace, 22s. to 23s. foundry, and 25s. special foundry.

The Electric Light.—The electric lighting committee of the Swansea County Council reported at the recent monthly meeting that, after consideration of a report from Mr. Preece on lighting some of the main streets of the town by electricity, they had decided to accept the tender of Messrs. Crompton to erect twenty-three arc lights of 2,000 candle-power at a cost of £25 each per annum, the increased charge for which over gas would be £171 per year.

BARROW-IN-FURNESS, 7th January, 1891.

Hematite.—Less business is being done in hematite pig iron. Orders are not being liberally given out, and buyers are not apparently anxious to place orders for either prompt or forward delivery. Business in iron to a great extent depends on the activity of the steel trade, and this is more apparent year by year as the Bessemer and the Siemens-Martins departments of trade are developed. Prices this week are easier at 52s. 9d. per ton for warrants net cash, and 53s. 6d. for Bessemer parcels in mixed numbers net f.o.b., while forge and foundry iron is quoted at 52s. 6d. The additional furnace which has been lighted, making fifty now in blast, has resulted in increasing the output, and also in an increase in warrant stocks for the first time for several weeks. These stocks have increased 393 tons during the week, and now stand at 211,398 tons. The stocks held by makers now represent about 40,000 tons of metal.

Steel.—There is less activity in the steel trade, as well commercially as industrially. Orders for rails are in the market, but are not of large dimensions. In the Barrow district the mills are busy, but in West Cumberland they have been indifferently employed for a month. Prospects are, however, rather better. Prices are at £4 17s. 6d. for heavy sections, £5 17s. 6d. for light sections, and £7 for colliery rails. Tinplate bars are easier in demand and lower in price at £5. Other departments of the trade are fairly but not briskly employed.

Iron Ore.—There is a steady market in iron ore at 11s. 6d. to 12s per ton for average qualities. There is more business being done in native qualities of ore than for some time past.

Shipping.—There is less activity in shipping. The exports of pig iron from West Coast ports during the week amounted to 11,378 tons. There were no steel exports. Last year the combined exports of pig iron and steel represented 20,096 tons, a decrease of 8,718 tons.

The Vulcan Steel Forge Works.—The rumour is again current that the Tubular Frame Waggon Building Company, Limited, have purchased the Vulcan Steel and Forge Works, at Barrow, which have been idle for some time. It is reported that they are about to put down the necessary plant, as they have secured a large amount of colonial and foreign orders which require early attention. The rumour, however, has not received official confirmation.

MIDDLESBROUGH, 7th January, 1891.

Pig Iron.—The quarterly meeting of the North of England iron trade was held yesterday on 'Change. There was a good attendance, but the amount of business done was not much. The ironmasters' returns had come like a blight and withered the hope of a revival. No. 3 G.M.B. drooped to 42s., and even 41s. 9d. per ton, whilst warrants were sold as low as 41s. 7½d. East Coast hematites are quoted at 55s. per ton.

Shipments of Pig Iron.—The shipments for the past week have been very poor, owing to the holiday time and the severity of the weather. The shipments for December as a whole have turned out much better than was expected. They amounted to 57,552 tons, as against 45,172 tons in the previous December. Of the 57,552 tons, the foreign amounted to 20,092 tons, against 26,782 tons the previous year, and the coastwise to 37,460 tons, against 18,390 tons the previous year. The year's shipments amounted to 804,208 tons, against 959,311 tons the year previous.

Manufactured Iron and Steel.—Both of these are very dull, and prices have become poorer than ever. Iron ship plates are quoted at £5 15s.; angles, £5 10s.; common bars, £5 15s. per ton; steel ship plates, £6 2s. 6d. (and 2s. 6d. less in some cases); and steel rails, £4 17s. 6d. per ton. The shipments of manufactured iron and steel for the past year amounted to 506,271 tons, against 527,358 tons for the previous year.

Ironmasters' Returns.—There are 101 furnaces in blast, against 103 in November, the two blown out being in hematite. The make of December amounted to 240,328 tons, against 235,849 tons in November, being an increase of 4,479 tons. Stocks have increased by 30,877 tons. The make of pig iron for 1890 amounted to 2,846,089 tons, against 2,771,180 tons the previous year. Stocks on the 31st December, 1890, stood at 256,262 tons, against 262,385 tons on 31st December, 1889, being a decrease of 6,123 tons.

SUNDERLAND, 7th January, 1891.

Shipbuilding and Marine Engineering.—The work of the past year has been generally satisfactory, both as to extent and in other respects. Local marine engineers have been more able to cope with the work of supplying the engines and boilers to all the vessels built on the river during 1890. Eighty-one marine engines, together with the requisite boilers, were constructed locally, including one or two "conversions," as against 85 steam vessels launched on the river. In the previous year, out of 99 steamers built at Sunderland, only 68 were engined on the river. The North East Marine Engineering Company, Limited, South Dock, has had the greatest output for 1891, viz., 23 marine engines from the Sunderland works, and 29 from the Wallsend works, or a total of 52 engines, of 48,500 i.h.p. Messrs. Geo. Clark, Limited, Southwick Engine Works, rank next in number of engines constructed, viz., 22 (including 1 "conversion"), of about 25,600 i.h.p. Mr. John Dickenson, Palmer's Hill Engine Works, constructed 18 engines, of 30,300 i.h.p; Messrs. Wm. Doxford & Son, Pallion, constructed 9 engines for new vessels, of 19,320 i.h.p., besides converting the engines of the "Alphonse Parrau"; and Messrs. Wm. Allan & Co., Scotia Engine Works, constructed 9 marine engines, of 7,680 i.h.p. The engines constructed here in 1890 were triple expansion, except three, which were of the "quadruple" type.

The Shipping Trade.—A serious depression is being experienced by shipowners. Local owners are taking the wise course of "laying up" their vessels rather than of working them at a loss, and already forty steamers belonging to the port are idle on the Wear and the Tyne. The tonnage afloat being so enormous, the prospects of steamers with compound engines appear very dubious. The coal shipments fell last week to 55,598 tons. In other departments the falling off was not so marked.

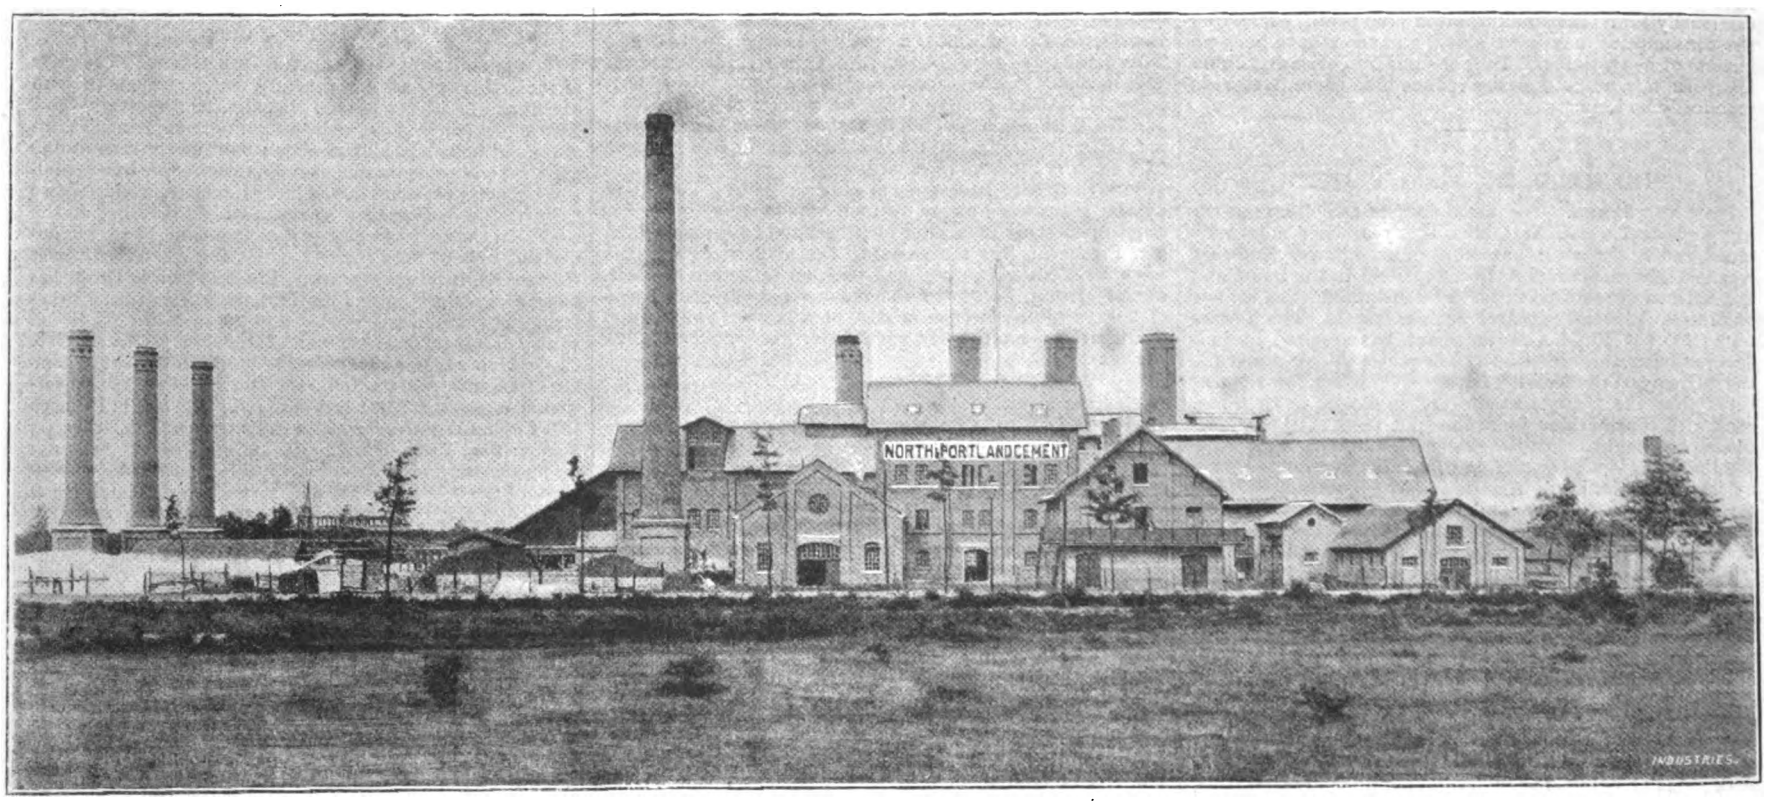
NEWCASTLE, 7th January, 1891.

The Coal Trade.—The opening of the year is marked by a slight improvement in the coal trade, the demand for both gas and manufacturing qualities being somewhat better than it was a month ago. The stoppage of pits for the holidays has brought the quantities held in stock considerably below the normal standard, and this circumstance is also helping to stimulate business. Steam coals are in less request, but the falling off in this branch is fully counterbalanced by the quickened demand for household coals caused by the present severe weather. The shipments of coal and coke at Tyne Dock during the week ending on the 3rd inst. amounted to 81,600 tons. This, though exceeding by 5,676 tons the shipments for the corresponding week last year, is much below the average of recent weeks.

Shipping.—Owing to the unremunerative state of the freight market, local shipowners are now finding themselves under the necessity of laying up some of their steamers, and already there are no less than twenty-six vessels, representing a carrying capacity of nearly 50,000 tons, laid idle in the Tyne. It is stated that arrangements are being made for the immediate laying up of a further number of vessels, the aggregate tonnage of which will exceed the figure stated above, so that, by the end of the month, at least 100,000 tons of shipping will be laid up between Newcastle and Shields. The shipowners have doubtless been compelled to resort to this expedient to save themselves from a greater loss than is involved in the mere laying idle of vessels, but it is a policy which they are usually very slow to adopt. There is reason to believe that, on the present occasion, its adoption has been precipitated by the aggressive tactics of the trade unions.

Tinplate Workers' Wages.—The tinplate workers of the district are taking steps to secure such an advance of wages as will bring the weekly rate up to 32s. Efforts are also being made to increase the membership of their union.

BELFAST, 7th January, 1891.



Shipbuilding.—Work after the Christmas holidays was resumed at the beginning of the week. A large number of vessels in hand are in a forward condition, which will serve to make up the tonnage for 1891. The output for last year was rather below that of the previous year, but when the class of vessels launched is considered, and compared with that of other yards showing a large tonnage, Belfast yards will be found to take a very high position.

Engineering.—Machine and tool makers are fairly busy, and some good foreign orders are in hand. Marine engineers are fully employed, and some firms are working overtime. Ironfounders are very busy, but in many cases the men have not returned to their work after the holidays.

Linen Trade.—Stocks of yarns are now low, and business will improve. Line wefts are in good demand, and bring 3s. 6d. per bundle, while rather more is asked for prime quality. Prices of tows remain firm, and producers have sold well ahead of them. Hand-loom cloth is in good demand, but the sale of power-loom is small. Prices, however, remain firm.

THE MANUFACTURE OF CEMENT IN BELGIUM.

General View of the Beerse Cement Works near Antwerp.

THE MANUFACTURE OF CEMENT IN BELGIUM.

The recent progress of the cement industry in Belgium is well known. Its latest developments may be witnessed at the Beerse Cement Works, near Antwerp, on the Canal de la Campine, the property of Colonel North. The clay found here was formerly used for the manufacture of bricks. It was M. Alexis Mols who first entertained the idea of turning it to a better use. After consulting Dr. Michaëlis, one of the greatest authorities on the subject, M. Mols received from that expert so favourable a reply that he immediately commenced operations, and, with the aid of Colonel North's energetic support and capital, in less than a year erected the factory, which we illustrate above, and which, when the extensions now in course of construction are completed, will be almost without a rival.

The materials employed in the manufacture of the cement are the clay, of which we have already spoken, and chalk. To ensure regular proportions in the composition, the limestone and the natural clay are carefully weighed before being placed in the wash-mills. The slurry is then drawn off and milled wet by means of heavy millstones, after which it flows automatically into a large reservoir, where it is finally mixed. The importance of this part of the process has been duly recognised by M. Mols, and it is not too much to say that, after passing the wet-mills and the mixing reservoir at Beerse, the paste is absolutely homogeneous. We may note here, in passing, that throughout the process manual labour is reduced to a minimum. After mixing, the slurry is pumped on to the drying plates, where it loses almost all its moisture, and from the drying shed it is raised by elevators to the drying kiln. The kiln used is Dietzesch's continuous kiln. The dried slurry is charged at the top, and is heated by the gases escaping from the fire. The fire is situated half-way down, and the space between the fire and the bottom of the kiln, whence the clinkers are extracted, is such that, by the time they reach the bottom, the clinkers have so far cooled that they can be held in the bare hand. The process of extracting the clinkers at the bottom and charging the dried slurry at the top is repeated, and the working of the furnace is thus continuous.

Among the advantages of this process may be noticed the following:—The cold air coming from the bottom of the kiln, while serving to cool the cement-clinker, gradually warms as it approaches the fire, and there is no loss of heat. In this way the necessity for a separate cooling chamber is abolished, and, as the imperfectly burnt cement is sorted out immediately on its extraction from the kiln, a great saving of labour is effected. After the most careful sorting, the clinkers are reduced to a coarse powder by means of stone-breakers, and then raised by elevators to the mills, where they are ground so fine that, at the final sifting, only 5 per cent. of refuse is left on a sieve of 75 meshes to the inch. To ensure absolute purity, all clay after extraction is washed, and then run into reservoirs, where the clay and sand deposit themselves in separate layers. The washing machinery, though at some distance from the works, is driven from the central motive power by means of cables.

After grinding, the cement is transported by endless screws, and left for three weeks or a month, after which it is packed, for inland sale in sacks, and for export in barrels. A cooper's shop capable of turning out 3,000 barrels a week is an instance of the completeness with which the works have been constructed. The whole is lighted by electricity. All repairs are done on the premises in completely fitted-out repairing shops. The result of this completeness is that the cement can be offered for sale at the lowest possible price.

In a well-appointed laboratory experiments may be witnessed which give conclusive evidence of the excellence of the cement. Two samples of mortar, composed each of three parts of sand to one of cement, the one after seven days, the other after twenty-eight days, give respectively tensile strengths of 170lb. and 398lb. per square inch, whereas the conditions for Government contracts only require 113lb. and 213lb. Two samples of pure cement, after the same periods, are found to give 569lb. and 880lb. per square inch, Government conditions demanding only 355lb. and 640lb. under the same circumstances. These tests are made with the testing machine invented by Dr. Michaëlis. Due consideration has been given to the fact that a quick-setting cement is useless when exposed to sea water. North's Portland cement is so composed that the setting is not complete for three hours.

A quay of more than 980ft. in length along the canal, now in course of construction, will complete a handsome frontage. M. Mols, the managing director, has a house adjoining the factory. The post of resident engineer is competently filled by Mr. J. W. Brough, Assoc.M.Inst.C.E.

COAL DUST IN MINES.

A study of the record of the most disastrous coal mine explosions shows that some of the most terrible of them have occurred about this time of year, a fact which was supposed to be due to the great and frequent changes of temperature and the consequent sudden outbursts of gas. The minute by the Secretary of State for the Home Department, which has been forwarded to Her Majesty's Inspectors of Mines, is issued, therefore, very opportunely, and will be carefully studied by all interested. Mr. Matthews says that his attention has for some time been directed to the effect which the presence of coal dust in mines may have in originating or in propagating explosions, and that two disastrous explosions have occurred in the course of the past year, at the Llanerch and the Morfa collieries, which have given fresh prominence and importance to the question. Both of these explosions were made the subject of careful investigation by competent men, and various theories were put forward to account for their origin and course by the presence of gas, but those theories were not considered to be sufficient, and it was thought that there were many of the explosions which were extended and assisted, if they were not caused, by coal dust. Mr. Matthews felt the great importance of arriving at further information and more certain conclusions on this subject, and he sanctioned the proposal of Mr. Hall, Her Majesty's Inspector of Mines, to conduct experiments for the purpose of ascertaining whether an explosion can be caused by blasting operations when coal dust is present, and in the entire absence of gas or fire-damp, a point on which he and other inspectors of mines had previously expressed positive opinions—which, however, only met with partial acceptance. The conclusion which Mr. Hall deduced from his experiments is that a blown-out shot may, in the presence of coal dust, and in the entire absence of fire-damp, cause explosions of great violence, often accompanied by volumes of rushing flame travelling considerable distances, and possibly so far as the supply of coal dust continues. Mr. Matthews points out that these experiments do not by any means exhaust the field of inquiry which he proposes to pursue with the best scientific assistance he can obtain. He, however, considers it to be his duty to lose no time in bringing before colliery owners, agents, and managers the results already obtained, and the serious dangers to which the presence of dry coal dust in mines may not improbably give rise. While, of course, he insists on the necessity of the provisions in the Coal Mines Regulation Act, 1867, with respect to shot firing in dry and dusty places, being rigidly observed, he is of opinion that prudence requires more than those provisions enact. He, therefore, strongly urges upon colliery managers that in every mine of at all a dry and dusty character the accumulation of dry coal dust should be prevented by removing the dust and watering workplaces and roadways (roof and sides as well as floor); and further, that shot-firing with gunpowder should only take place when all the workmen have been withdrawn from the seam. He does not think that any fresh legislation can be usefully attempted until the subject, both of the danger which coal dust may cause and of the means by which that danger can best be met, has been fully investigated by competent scientific men.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 9TH JANUARY, 1891.

THE INVESTMENT OF ENGLISH CAPITAL IN AMERICAN INDUSTRIES.

SINCE the passing of the McKinley Tariff Act special attention has been paid in this country to the advantages which the English capitalist might obtain by the investment of his money in the development of American industries. In the autumn of last year some of our contemporaries gave glowing accounts of Pittsburgh and Baltimore, and pictured them as the chief seats of the future American tinplate industry, while pointing out the prejudicial effect that such a development would have upon the manufacture of tinplate in South Wales. Now that a reaction has set in against the Republicans in the United States, there is some ground for believing that the excessive tariffs may be reduced, and this should cause manufacturers here to hesitate before making so radical a change as the complete transference of their industry to a country with a rapidly varying commercial policy. During the last few years many of the American industries have undergone a process of recapitalisation, and have passed out of the hands of the original owners, who have sold their concerns to English capitalists. Many leaders of English industry have also found it to their advantage to start factories in the United States on an extensive scale. For example, some of the large breweries in the American towns have passed into the hands of the English capitalist within a comparatively short period, and it seems as if other industries of an allied nature will speedily be developed in a similar manner. Shortly after the passing of the McKinley Act it was stated that new tinplate works, costing from $1,000,000 to $5,000,000 each, were to be built immediately in Baltimore, Pittsburgh, Chicago, Colorado, and Alabama, and that tinplate manufacturers from this country were concerned in these projects. These statements seem to have originated in part from overtures made by the Pittsburgh Chamber of Commerce to some of the Welsh tinplate makers, with a view of inducing them to erect plant in that city. Tinplate iron has been made for some time in a few of the rolling mills in the United States, and the American manufacturers would have tried before now to introduce this particular industry, even without the advantages of the increased tariff, had a supply of tin been available. At the present time tin has to be imported into the States, and, as it has not been exempted from duty, a tinplate manufacturer at the outset starts at a disadvantage, for which the present tariff may not sufficiently compensate. The cost of sheet iron manufactured in the United States is also increased by the extra cost of nearly everything connected with its production, and this renders the possibility of the industry being a profitable one still more remote. No doubt in time the vast mineral resources of California, Dakota, and other tin-yielding districts in the United States, will yield sufficient tin to supply any demand of this kind; and, when such a home supply becomes available, the tinplate industry will be possible in that country. In the returns of our metal exports to the United States tinplates form a most important item. During the year just completed tinplates exceeding £4,600,000 in value were shipped from this country, but under the new tariff the duty will be increased from 34 to 76 per cent. *ad valorem*. It must, however, be borne in mind that a considerable portion of this amount is used for package, and that buyers for this purpose will be able to obtain a drawback from the revenue authorities on a declaration to that effect. Recent advices show that that the United States Iron and Steel Company, of Demmler, and an important firm at Apollo, intended to commence this manufacture at an early date, but in all probability the industry will remain a tentative one until the modifications of the present tariff law by Congress are fully known.

Although we do not believe that the industry just referred to would have been created in the United States as the result of the recent tariff alterations, even if their permanence had been assured, still there are many existing metallurgical industries in the States which seem likely to be developed by the employment of English capital in the near future. This development seems to us to be not only independent, in a large measure, of the McKinley Act and future modifications of it, but dependent upon what we may term a general and a special reason. The general ground on which we base this belief is to be found in the fact that the rate of interest in this country differs from the rates in the new towns of the United States. In London a 5 per cent. rate of interest may be regarded as a satisfactory return on invested capital, while much larger rates obtain in the American cities. A Chicago owner, for example, accustomed to receive 10 or 12 per cent. on his capital, can be easily induced to part with his business if a price which is considerably above the amount of money he has sunk in it be offered. The English buyer can afford to pay such increased price if he can be assured that the undertaking is a sound one, as he will still be able to receive a rate of interest equal to, and in many cases higher than, that which he has been receiving at home. The *Chicago Economist*, in a recent article on this subject, compared capital held at different rates of interest in parts of the world remote from one another to two bodies of water standing at different levels. As soon as a connecting channel is made they immediately assume a common level, and as soon as the genuineness of any American enterprise has or can be ascertained by the investing public, there is no reason why the business of recapitalising American industries and selling the securities should not go on indefinitely until the two countries give an equal rate of interest upon investments. A special reason why this transference should take place in American metallurgical industries has been supplied by the visit of the Iron and Steel Institute to that country in the autumn of last year. In fact, Sir James Kitson, when visiting Washington, is reported to have said, in conversation with the President, "The gentlemen of our party have come to the United States to ascertain where they can invest their money profitably. There are wonderful resources all through the South, which must be developed, and British capital will undoubtedly find an outlet there, and with gratifying returns for the investors. This is the consensus of opinion of our party, 350 in number." Such an expression of opinion from Sir James Kitson, as spokesman of a body of metallurgical

Digitized by Google

experts, cannot be without great significance, and those of our readers who have followed our recent articles on the mineral wealth of the Southern States will not fail to realise that the visit of the members of the Iron and Steel Institute to that part of the country must tend to hasten the development of American metallurgical industries, and cause a large influx of British capital into the United States.

It should not, however, be forgotten that foreigners are at a disadvantage in carrying on industrial work in other countries. In most countries there is a disposition, more or less pronounced, to regard such persons as intruders, and in some cases there are legal and other impediments to fair trading. In the United States there are indications of this spirit apart from their Protectionist policy. At the present time there exists an Alien Land Act, which restricts the holding of land in the United States by foreigners, and a Bill is now under discussion to extend the existing Act to all limited liability corporations other than railway companies. In the event of the Bill becoming law, the companies holding land in the States will be placed on a similar footing to the private individual, and many of the large ranching companies, brewery corporations, and other bodies, whose capital has been found in this country, and who are now trading as American firms, will be considered as aliens, and will thus be handicapped in their competition with non-alien enterprise.

DYNAMO BRUSHES.

The weakest part of a dynamo, taken as a machine, is the commutator, with its brushes, and no part has undergone so little improvement. Our American contemporary, the *Electrical World*, holds that a direct current dynamo must be made without a commutator. A method of making an alternating current machine without even a commutator in its exciting circuit, by exciting the fields by means of a leading current in the armature, has been proposed; and if the armature is stationary, and the field rotating, such an alternating machine would have neither commutator nor collector in its construction. Apart from its exciter, an ordinary alternating machine must have collecting rings for its armature, or field circuit, and so the alternating dynamo is in the matter of commutators rather behind the "unipolar" direct current machine. The unipolar machine cannot, however, be made to give more than one or two volts. Such a generator with many armature turns is, of course, an impossibility. It would involve an electric circuit so arranged that "lines of induction" could continually cut into it without cutting out again. They would have to accumulate these indefinitely. The *Electrical World's* prophecy may come true all the same in some unexpected way. A self-exciting alternator with no magnet coils does not at present sound very possible.

In the meantime, however, direct current machines need commutators and brushes. A great many things have been tried. The old machines had bundles of hard copper wires, which were allowed to get twisted and tangled till they resembled little birch brooms. They were permitted to wear down the commutator as fast as they would. Now, however, machines are made so that, with care, the commutator is worn down very little, but with varying loads there is still great trouble. Is it possible that the problem has never been dealt with from the right point of view? Copper was probably chosen for the commutator and for the brushes with some vague idea that its high conductivity was important. From an engineering point of view, however, no one would run copper on copper and expect good results. Then, again, tangent brushes must tend to increase any unevenness, because it sets them in a state of vibration. Tangent brushes are seldom, if ever, used now, except on "open circuit" commutators, and the end-pressing arrangement is much better. Even then the brushes act to some extent like a lathe tool, and it is important to make them collect without "seizing" or cutting. An engineer, untrammelled by electrical notions, would never run a copper commutator with copper brushes. Copper on copper, or even brass on brass, runs notoriously unsatisfactorily. He would choose some very hard material, like steel, for the commutator, and use brass for his brushes. Steel or iron was used in the earlier dynamos, and has been used more recently by Ferranti for the collecting ring in alternating current machines, but when employed in the commutator the sparking was excessive. Now that that vice is almost non-existent, it would be interesting to see if iron or steel could be used. If not, there are many very hard and durable alloys that might be employed. Messrs. Crompton & Co. have made considerable use of aluminium-bronze. Of course, one important point is, that the commutator sections must be easily cast or drawn. In America, where stock types of machine are always used, the case is not quite the same as here, where the dynamo maker has to make each dynamo to order to suit some particular consulting engineer. Brushes have been made of all sorts of arrangements of brass or copper, but of little else. Professor Forbes used carbon in his experimental unipolar machines, and carbon has come into use extensively in the United States, especially for motor work. Probably the reasons why it works well are that it does not "seize" on copper or phosphor-bronze, and that its resistance is so high that the current dies down when a commutator section is being uncovered. The area of carbon contact becomes smaller, so there is a resistance inserted which reduces the current in the same way as Dr. Hopkinson and others some years ago sought to reduce it, by using several brushes with resistances in their circuits. A carbon collector is apt to make the commutator hot. In America it is frequently used in conjunction with copper brushes, the carbon being put farther forward, so as to reduce the spark, while the copper collects the main current. Copper gauze was recommended and used a few years ago, and it has again come to the front. It seems to be soft enough to fit the commutator closely, and its fibres can yield and follow any unevennesses in the commutator without making the whole brush and its holder vibrate, thus causing "flats." To secure this springiness the brushes are made by what ladies call "cutting on the bias"—that is, cutting the gauze so that the meshes are always presented diagonally to the commutator. A similar principle underlies a form of brush used in the United States. It is made of fine wires, but instead of being laid side by side, they are plaited into cables, several of the cables being used for each brush. Some of the aluminium alloys have been tried for brushes in England without much advantage; so, also, has German silver. There is no need to mention the various arrangements that have been proposed to lessen the effects of varying loads by automatically shifting the brushes or by the use of reversing pole-pieces. The commuting arrangements of direct current machines, especially motors for varying loads, are worthy of the most serious attention.

THE "P. & O." COMPANY.

The honour of Knight Commander of St. Michael and St. George, which has been conferred on Mr. Thomas Sutherland, M.P., the Chairman of the Directors of the Peninsular and Oriental Steamship Company, has not only been universally recognised as well deserved, but also has recalled the remembrance of the fact that on the last day of the year, fifty years ago, the company received its Royal Charter, and marked an interesting date in the history of steam navigation.

In 1835 the company was started in a very small way by a firm of brokers in London, and was intended at first to carry on trade between this country and Spain and Portugal. In a very short time it saved the Government a very considerable sum per annum by superseding the Government packets to Lisbon and Gibraltar, and hence the origin of the first part of the company's name. But the Peninsular has long since been dwarfed almost into insignificance by the Oriental share of the business, while that, on the other hand, is being equalled by the Colonial—a fact which is brought out by the Chairman receiving an honour which is always conferred only for services to the Colonies. The company soon extended its service to Egypt, again superseding another set of Government packets, and justifying the addition of Oriental to its original name. The development of steam navigation naturally led to a desire for steam connection with India, and hence the evolution of the "P. & O." In 1840 the company secured a Royal Charter, by which they agreed to establish steam communication to Calcutta within two years, the East India Company undertaking to pay premiums on a certain number of voyages per annum, with a maximum of £20,000.

The progress which has taken place in shipbuilding and marine engineering since those days, and which has been so well maintained by the P. and O. Company, has been very striking. Their first steamer was built of wood, and was only about 200 tons burthen. She was propelled by side paddles with engines of 60 horse-power, working with about 7lb. pressure of steam, but, being rigged as a schooner, she depended more on her sails than on her engines. When the voyages were extended to Egypt the "Great Liverpool" was built, of 1,311 tons and 464 horse-power. The new Indian traders were larger, the first, the "Oriental," which was built in 1840, and the "Precursor," in 1841, being about 1,800 tons, and in these and their successors the old side lever engines were developed to a stately style of architecture. The first iron ship built for the company was the "Pacha," in 1842, and three years later wood was altogether abandoned. The screw propeller was first adopted in the "Shanghai," in 1857. The making of the Suez Canal and the development of the compound marine engine have done much to revolutionise the trade of India and the Colonies. In 1842 a monthly mail service was started between Calcutta, Madras, Ceylon, Aden, and Suez, and two years later the company entered into a contract with the Government to carry the mails on to Singapore and Hong Kong, for which purpose they had steamers built averaging about 1,000 tons and about 450 horse-power. The next development was a service to the Australian Colonies, and from that time the size of the ships has gone on increasing, all the most recent additions being about 5,000 tons burthen and with triple-expansion engines.

The effect of all these improvements has, of course, been a great reduction in freights. To go no further back than 1869 goods to Bombay were charged from £10 to £12; to Madras and Calcutta, £16 to £20; and now the rates vary from 20s. to 30s. per ton. To China, Australia, and Japan the reduction is much more marked.

THE INSTITUTION OF CIVIL ENGINEERS.

The Institution of Civil Engineers is now the most important engineering society in the world, and its Proceedings are the most valuable records of engineering progress in existence. At its meetings everything of importance in the engineering world is passed in review, and the discussions which take place afford a most useful school for all classes of engineers, old as well as young. It is felt, however, that even engineers can have too much in the way of stiff scientific material to be good for their intellectual development, and that an occasional round of something lighter and less formal would aid in the digestion of the heavier materials. With the view of making the proceedings of the Institution a little more varied in character, the Council have arranged that in future the first meeting in every month shall be got through quickly, and the remainder of the evening spent in conversazione style, when opportunities will not only be given for a certain amount of social intercourse, but also for the examination of exhibits of various kinds. An attempt will be made as far as possible to confine each of these special evenings to the same department of engineering. Thus, on the 13th inst., Mr. W. H. Allen, will contribute a paper on "Auxiliary Engines in Connection with the Modern Marine Engine." In connection with the paper will be shown specimens and models of various appliances. There are, therefore, likely to be found examples of air, circulating, and feed pumps, fans for ventilation and forced draught, refrigerating and distilling apparatus, reversing and turning gear, and electric appliances of all kinds. The idea is an excellent one, and will not only popularise the meetings, but give opportunities to the members to become personally acquainted, and thus benefit them intellectually, and no doubt, in many cases, commercially, more than if the whole evening had been spent in formal discussion.

THE CHICAGO EXHIBITION

The President of the United States of America has now formally recognised the great Exhibition which is to be held in Chicago in honour of the fourth centenary of the discovery of America by Columbus, by issuing a proclamation calling upon all engaged in industries to support the undertaking, and inviting foreign Governments to assist the project. Copies of this document will be sent to foreign Governments, and until replies have been received it will be impossible to say to what extent the Exhibition will be international. No doubt other nations will be guided to a very considerable extent by the action of Great Britain in the matter. As we have already pointed out, there is considerable doubt whether the matter will be taken up very enthusiastically in this country, as our manufacturers have little or nothing to gain by it, and might possibly be involved in a great deal of expense. Moreover, it is doubtful whether our Government will take up the matter officially, for although the Exhibition has been recognised by the United States Government, and assisted financially and otherwise by the Government and the State authorities, it is a private project in itself. It is to be hoped, however, that our

Digitized by Google

Government will take the initiative in such steps as will show, at least to the people of the United States, that it wishes the undertaking all success, and is willing to do something to forward that success. The resources of the United States are no doubt very great, and sufficient to make a most attractive and instructive show, but it will be a great disappointment to the Americans if they fail in their desire to make the Exhibition a real World's Fair.

THE INSTITUTION OF ENGINEERS IN JAPAN.

Some idea of the progress of engineering and engineering education in Japan will be formed when it is stated that the Institution of Engineers in that country now contains 11 honorary members, 353 members, and nearly 1,000 associate members. The President is Viscount Yamou Yoso, who was for a good many years Acting Minister of Public Works. The honorary members consist of nine Japanese of high office or scientific attainments, and two foreigners—Henry Dyer, M.A., D.Sc., the first Principal of the Imperial College of Engineering, and his successor in that office, Dr. Edward Divers, F.R.S., who is still in Japan. The list of members includes all those who are actively engaged in superintending the numerous engineering works and manufacturing industries all over the country, while the associates are connected directly or indirectly with those works. When it is remembered that it is only seventeen years since the Engineering College was founded, and only a little over ten years since the Institution was organised by the first graduates from the College, it will be seen that astonishing progress has been made.

Letters to the Editor.

IS THE STUDY OF THERMODYNAMICS OF USE TO ENGINEERS?

To the Editor of "Industries."

Sir,—The question at the head of this letter occurred to me after reading your review of Professor Cotterill's book on "The Steam Engine Considered as a Thermodynamic Machine," which appeared in your last issue. I had previously read a considerable number of other notices of the book, and had, moreover, tried to make myself acquainted with the book itself. If the author of such a treatise places any weight on the opinions of his critics his mind must be in a very unsettled condition at the present time with regard to the merits of his book, and, in fact, of the use of a great deal of his daily work, for which he is paid a good salary by the British Government.

It seems to me that your notice is the fairest of all that have appeared, as it points out clearly the scope of the work and the class of men to whom it will be useful, while it also indicates some improvements which might be made upon it. You point out that the book treats of what may be called the physics of the subject, and explains the phenomena which occur in the use of steam, without, however, bringing the results into the shape immediately useful for practical calculations—that is to say, it is an educational book, which while it leads in the direction of practical applications, is intended primarily for the purpose of elucidating phenomena. The notice in *Nature* concluded by saying "that from the point of view of the student of physics, the book forms a most valuable supplement and corrective to the necessarily abstract discussions which form the substance of treatises on theoretical thermodynamics."

The notice which has puzzled me, however, is that which has appeared in your contemporary *The Engineer*. While admitting that the book will interest the closet philosopher, the man who takes delight in pretty problems and hypotheses, however useless; and also the man who—like some of the old mathematicians—would not consider his thermodynamic abstractions any the less important because they cannot have any practical application, the writer concludes by saying that engineers, upon whom this great steam engineering nation depends for all that is done by the splendid engines of all kinds to-day, would waste their time if they tried to gain anything from this book; and further that "the progress made since 1877," of which the author speaks, has been made in spite of the teaching of the first edition of the book, and of the teaching of others of the same kind. Of course I know some of the peculiarities of your contemporary when treating the subject of Professor Cotterill's book, but surely statements of this sort should not be allowed to pass without contradiction and without demonstration of their incorrectness. Those of your readers who are at the same time practical engineers and students of thermodynamics would confer a great favour on the younger members of the profession if they would give their opinions on the subject.

Yours, &c.,
Student.

Glasgow, 3rd January, 1891.

THE EFFICIENCY OF STEAM JACKETS.

To the Editor of "Industries."

Sir,—Your interesting article on Professor Thurston's historical paper upon this subject will, I hope, produce some comments or experiments from competent engineers.

When we consider how easily steam jackets are misunderstood, and how often misapplied by making them into air or water jackets, such an inquiry may be expected to reveal a great variety of results and much want of uniformity. We find in the above paper many kinds of piston speeds, with various strokes, cylinders of different diameters and in different positions, vertical or horizontal. The pressures of steam, expansions, pressure in the jackets, supply to the jackets, and the quality of the steam also vary much in the different engines.

Few people fix a steam gauge on their jackets to check the pressures and temperatures, and to ascertain whether the steam supply to the jackets is large enough. A cock at the highest and lowest points of the jacket should also not be omitted, to test for steam or water.

The "quality" or dryness fraction of the steam used in the engines has, no doubt, as you say, a considerable influence, but unfortunately there is much difficulty in testing the steam, since no reliable instrument at a moderate price has hitherto been offered to the public.

Further, there is the important question of the temperature of the cylinder walls, and of all the internal parts exposed to the working steam. All these have a marked effect on the hot steam. These walls should be kept generally at the highest temperature available, and certainly hotter than the initial steam. With the same quality of steam, and with walls at two different temperatures, the hotter wall will doubtless yield the most economical results. Where the walls are of the same temperature, and working with steam of different qualities, the dryer the steam the better will be the result. My experiments show that the temperatures of cylinder walls are some 30° F. hotter with steam in the jacket than without. An economy of 31 per cent. due to the jackets was obtained with a small fast-running single-cylinder condensing vertical engine. For every pound of water deposited in the jackets about 5lb. were economised in the cylinder.

With vertical cylinders it is not difficult to divide the barrel-jacket water into two parts, and collect the water separately from the two vertical cylindrical surfaces of the jacket space—that is, from the inner and the outer surface. It is only the former which represents the useful heat going through the metal walls and keeping them hot; the latter shows simply the loss due to useless radiation, which should be reduced to a minimum.

Lately I have had an engine working (1) with steam in the jackets, (2) with hot water, and (3) with hot air in the jackets. The results are interesting and instructive. Of course, the air and water were, in each case, allowed to acquire their normal temperature before commencing, all other conditions remaining the same. The very different results obtained with jackets of steam, of water, and of air were afterwards compared.

CHEAP FOOD OR WANT?

To the Editor of "Industries."

Sir.—Want or semi-starvation for the masses, the impoverishment of many capitalists and manufacturers, and agitations leading possibly to riots, appear to threaten, unless cheap, healthy, abundant food is speedily secured for our poor and comparatively poor.

Man by labour or inherited labour called wealth must get fed regularly and fed cheaply. His digestion requires a wide and varied diet. In our cold, damp climate, where sunshine is comparatively rare, every man should obtain at least one daily meal of fish or meat. Owing to faulty distribution and preservation, much of the fish and meat consumed by the poor is often wretchedly inferior and exorbitantly dear. Hence, perhaps, their excessive tendencies to alcoholic drinks and tobacco, which at least please their palate.

The producer provides cheap excellent frozen meat, poultry, and game, which too rarely reach the consumer except when sold as and at the high prices of home-bred, fed, and killed animals. Legislative interference should prohibit such fraudulent trading. Our fresh food markets, whose charters and existence were granted to bring the producer and public together, are now usurped by a handful of capitalists who have cleverly "cornered" the public markets and their entire fresh food supplies so as to sweat the producer, semi-starve the masses, and overcharge the classes. Cobden's Free Trade principles have been so engineered that the producer gets no profit because the middlemen gain all.

As regards fish the Billingsgate "ring" excludes the public, the fishmongers, and the costermongers, from purchasing except from the "ring," who cling to perpetuating bacterial Billingsgate, with all its avoidable abominations and augmenting abuses. Hence stale fish continues at famine prices instead of cheap, fresh, imperishable fish.

Every day of the year 2lb. of bled, gutted, cleaned, dry-air frozen (imperishable) fresh herrings (about six fish) could be profitably retailed by costermongers for one penny, or 2lb. of sprats for one halfpenny.

The Billingsgate "ring," by a shrewd system of cruel crushing mortgages on the uncaught and caught fish, enslave and impoverish the indebted fishermen. According to Cahill's evidence before the Corporation, 1881, Fish Enquiry, "The practice in Billingsgate Market is that its 'ring' realises the highest price it can and returns the sender *what is expedient*, or what may be agreed on among its members. This 'ring' very often after agreeing on the price to the senders so distrust each other that they exchange account sales enclosed in open envelopes, so that 'A.' reads, seals, and posts 'B.'s' sales, and *vice versâ*."

To keep up the price of fish much is destroyed by the "ring," who ruin our national fisheries and fishing industries. Our manufacturers will soon be unable to compete with foreigners, who obtain cheaper labour because of cheaper food. Hence the land, buildings, and plant of the British manufactories will suffer increasing depreciation, their labourers and those dependent upon the earnings of the labourers will find their occupation gone.

With our large pauper, police, prison, and asylum establishments, and an expensive army and navy fed by the public purse, dear food means increased taxation. Hence the question of cheap, healthy, abundant food should be carefully considered by Parliament and the County Councils. By means of retail stores, and costermongers for the poor, the producer should sell fresh food direct to the consumer.

Yours, &c.,

OUR BIG GUNS, AND HOW THEY ARE MADE.

To the Editor of "Industries."

Sir,—I have read Lieut. R. R. Gubbins' letter in your last issue with considerable interest, but I must beg to draw his attention to a letter that I addressed to your contemporary *Engineering*, of October, 1886. In this letter the following explanation is given of what I consider to be the fatal defects of built-up guns:—

"With a rather considerable experience in the use of metals subjected to elevated temperatures, and knowing that metals of varying densities and chemical constitution had varying degrees of dilatancy and varied in their heat conductivity, or had variable diathermaniac characteristics, it seemed to me that, given an inner tube of a gun of a certain metal having a definite chemical constitution and physical density, surrounded with heavier coils shrunk thereon and of different chemical constitution, degrees of dilatancy, and diathermancy, and given that a certain quantity of heat were applied to the inner surface of the inner tube, the resultant action would be that the circumferential dilatancy of the inner tube, beyond the elastic limit, would be prevented by the heavy and cooler shrunken coils, and a surface fracture of the inner tube by compression would be very probable.

"To show the quantity and intensity of heat that could be accumulated in heavy guns, it was stated by Mr. Robert Wilson that the heat had been found sufficient to account for the melting of the soft particles of metal in bronze and cast-iron guns. Consequently, it was not unreasonable to conclude that the several local pressures acting upon steel tubes exposed to a higher temperature were sufficient to start the surface cracks in the steel tubes of large guns, and that neither the shrinking on of coils nor the coiling of wire would prevent the formation of these surface cracks. The degree of residual heat left from each charge must be considerable—even although the interval of time is so short as $\frac{1}{10}$th part of a second.

"The effect of continuous firing on some of these heterogeneous structures, unless adequate means of cooling were adopted, could hardly fail to be disastrous to the soundness of the inner tube, and the suggested increase of chase hooping, if the theories advanced are acceptable, would not be in the least a remedy."

Soon after this letter appeared the Elswick people abandoned the wrought-iron hoops and adopted mild steel instead. This is, so far, good; but what about the great number of guns on the old Armstrong principle of construction, spread over our centres of defence, and which are intended to protect many of the elements constituting our navy? Not one of these guns can be said to have the full confidence of our gunners.

Even with the shrunken hammered steel hoop, the guns are still radically wrong in their principle of construction, because the hoops have a different physical density to that of the tubes. The factors of diathermancy and dilatancy will vary, though not in the same degree as before.

What is required is a system of cast-steel guns, cast on a similar principle to that adopted by the illustrious Rodman, whose system of cast-iron centrally cooled guns decided the fate of the issue between the North and the South.

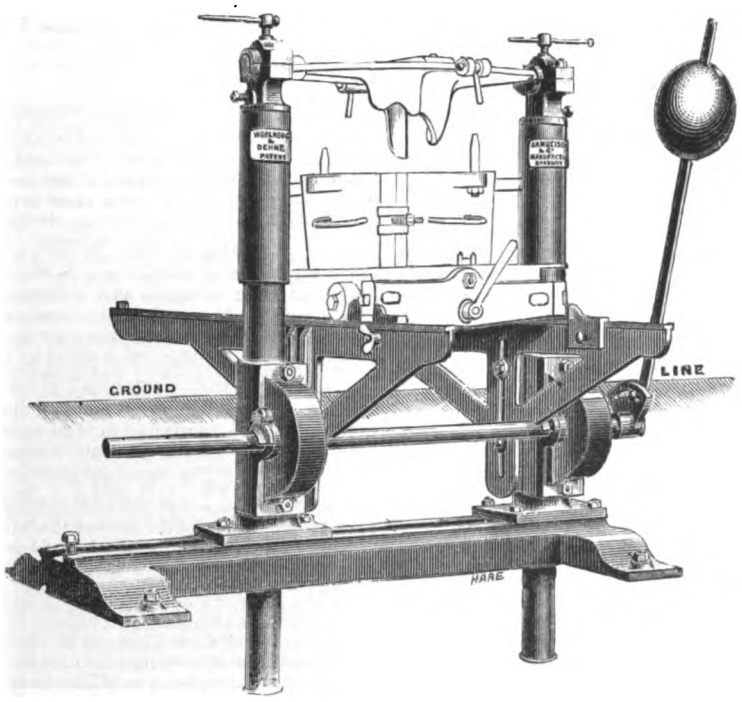
Yours, &c.,
B. H. Thwaite.

Liverpool, 5th January, 1891.

THE PHENOMENA OF THE DEPTFORD MAINS.

By J. Swinburne.

I.



In a paper on condensers, read at the Physical Society on the 12th of December last, I gave what I believe to be the true explanation of the phenomena observed in connection with the high-pressure mains from Deptford to London. This gave rise to considerable discussion at the meeting, and the matter has been still further investigated in the pages of the *Electrician*.

The contention in my paper was that the rise of pressure observed is not due to any sort of electrical resonance, as commonly supposed, but to armature reactions in the dynamo. I gave as my reasons against the resonator effect, that with the capacity of the cables, the frequency employed, and the actual self-inductions in the circuits, such effects cannot take place. I by no means denied that, under certain conditions, electric resonance can take place, neither did I deny that condensers, choking coils, and resistances can be combined in ingenious ways to give curious results; all I said was that the resonator effect could not occur in this particular case. The armature reaction theory seems to account for the phenomena, and I described an experiment made with a condenser, a transformer, and a dynamo which bore out my theory.

The resulting controversy is, to some extent, unsatisfactory. To invalidate my theory or to establish another, it is necessary, first, to show that armature reactions will not account for the phenomena at Deptford, and preferably that they do not account for the effect in my own experiment; and secondly, that such phenomena as those produced at Deptford can be obtained by electric resonance, or by combination of capacity and inductance, not taken at random and called L and K, but agreeing at least approximately with those existing in the particular case under discussion. I do not for a moment deny the great scientific value of the discussion in the *Electrician*, calling attention, as it does, to many curious and interesting results obtainable by coupling up appa-

IMPROVED MOULDING MACHINE.

General View of Machine.

ratus in particular ways; I merely say that it neither shows any error in my explanation of the rise of pressure in the Deptford mains, nor is any other given.

Before going farther into the question, I should say that I have for some time past abandoned the notion of "self-induction" in an armature of an alternating machine, and considered the questions of armature reactions only. In 1887 an alternator was designed for parallel running according to this theory, and it is referred to in some papers on electrical measurement contributed to the *Electrical Review* in that year, and reprinted in book form.* A patent for alternating motors, of February, 1889, depends on this theory. In the discussion on Mr. Mordey's paper on "Alternate Current Working," Sir William Thomson explained the action of the armature currents most clearly on the same principles.†

The orthodox method of dealing with alternating dynamos and motors is to treat them as if they had an "impressed electromotive force" which is independent of the load, and a coefficient of self induction. The coefficient of self-induction L of a dynamo is generally taken, so that $Ldc/dt = E$, the instantaneous back electromotive force which has to be deducted from the instantaneous impressed electromotive force to give the terminal electromotive force. This involves a confusion of thought. If, to use the orthodox expressions, the rate of cutting the lines of force gives the electromotive force, any alteration of the magnetic field due to the armature current, even if completely localised in the armature, merely alters the rate of cutting lines, and, therefore, the electromotive force. The idea of self-induction and electromotive force in the same moving armature depends on two distinct ideas of the same thing. The self-induction is treated as "electric inertia," and the pressure as cutting lines of force. We might imagine a dynamo with enormously powerful fields, so that one turn would give the output, and a small choking coil, with a constant coefficient of self-induction, arranged in series. This would be the analogue of the conventional alternating dynamos met with in discussions containing mathematical symbols. It must be admitted that, according to my armature reaction theory, the cross-induction makes the armature current lag as the load increases, and the back induction lessens the pressure, so that the effect looks like that of self-induction in the armature circuit. Like "magnetic resistance," the expression "self-induction of the armature" is convenient in speaking in a loose and qualitative way, and I have often so used it; but when quantities are dealt with "self-induction of the armature" will not explain the action of dynamos and motors on one another. I hope to discuss this subject more fully at some future date.

Turning to the main subject of this paper, my first critic is Mr. Kapp. At the discussion on my paper he referred to an experiment of his own. A dynamo fed the primary of a transformer. The secondary, wound for 14,000 volts, was connected to sparking points, which sparked $\frac{13}{16}$in. A cable was then put on, and the sparking distance increased to 1in. without any rise in the terminals of the alternator. The capacity of the cable was not given. Assume, as an outside figure, half a microfarad. Then, if the pressure rose from 14,000 to, say, 15,000 volts, with a frequency of 80, there must have been a self-induction of no less than half a henry somewhere between the sparking points and the transformer. It must have been outside the transformer, for the secondary pressure did not alter. I can only suggest that Mr. Kapp has here been misled by some rough experiments. The spark is not an accurate enough test of pressure. The existence of such a self-induction between the spark points and the transformer—that is to say, in the experimental connections—is quite impossible. This experiment was described by Mr. Kapp in the heat of a discussion, and may not, therefore, be representative of his views on these points.

Mr. Kapp has, however, contributed a long article to the *Electrician*, which, though addressed to the younger readers of that journal, refers to my paper and criticises the part dealing with the Deptford mains. He says that I am wrong in assuming that electrical resonance only occurs at one particular frequency. He does not appear to know what I meant by electrical resonance. On looking up Dr. Hopkinson's paper, referred to by Mr. Kapp, I find he also uses the term in connection with the effect of a condenser and self-induction in series at any frequency. This seems to me an inaccurate use of the term. To show what I mean, a rough analogy will suffice. Imagine a large watch-balance with a hair spring. The moment of inertia of the balance corresponds to the self-induction, the weakness of the spring to the capacity, the friction to the resistance, the force applied by the spring to the pressure, and the angular velocity to the current. Suppose, first, that there is no moment of inertia, the spring will give, so that its force exactly counterbalances that of the impulse, and never becomes greater. If the wheel has inertia, however, on applying an impulse it will first be opposed by the spring and inertia together, but towards the end of the movement the inertia will help the impulse to wind up the spring. The pressure of the spring is thus greater than if there had been no inertia; the movement of the wheel is also greater. Suppose that the frequency of the impulses is altered till it corresponds exactly to that of the balance, instead of vibrating through a few degrees the wheel will vibrate through an increasing angle, and this angle will grow till it becomes infinite, if there is no friction. This is the resonator action, and it only occurs when the frequency of the impulses corresponds with that of the balance. It is in virtue of this action that such a very small power can keep a large clock pendulum going. If two pendulums of slightly different lengths were connected to one scape wheel, it would take incomparably greater forces to drive them. If the balance has friction, its vibrations will not become infinite, but only large enough to absorb all the power supplied by the impulses. If the friction is very great—for instance, if the balance be immersed in a liquid—it will absorb so much power with a small movement that resonance will not show much. Mr. Kapp has, in his example, immersed the balance in treacle. Take, instead of fancy figures, the capacity, pressure, and frequency at Deptford, and see the effect of a variation of speed with the critical self-induction in circuit. Take the case of no load, and assume the dynamo and transformer to give 10,000 volts at Deptford. Take the capacity of a seven mile cable at 2·5 microfarads, and the resistance at 2·27, the frequency being 67. These last figures are from Dr. Fleming. Call E the maximum value of the pressure on the condenser or cable. As the capacity is distributed along the resistance, it may be taken as 1·14 ohm outside the condenser. Assuming the harmonic law, as is indeed permissible when rough results are alone wanted, we have

$$E_1 = E \cos 2\pi n t,$$

where n is the frequency. The current into the condenser is then

$$C = -K E 2\pi n \sin 2\pi n t,$$

and the electromotive force on the induction coil is

$$E_2 = -L K E(2\pi n)^2 \cos 2\pi n t.$$

The critical value of L is then found

$$L = \frac{1}{K(2\pi n)^2},$$

and is 2·37 henries.

The dynamo giving 10,000, E can be found from the following equation—

$$10{,}000 = \sqrt{\left\{E - L K E(2\pi n)^2\right\}^2 + (rK E 2\pi n)^2},$$

when there is resonance,

$$L K E(2\pi n^2) = E,$$

$$\text{so} \quad E = \frac{10{,}000}{rK\ 2\pi n} = 10{,}450{,}000.$$

With resonance then, instead of a rise of a few hundred volts over the normal pressure, we have a pressure of ten million and a quarter volts, which might even discourage Mr. Ferranti. This can only happen at the exact frequency of 67. Mr. Kapp thinks I was wrong when I said an alteration of 5 per cent. would stop the effect. Let us try a much smaller alteration of speed, say one-tenth of 1 per cent. This gives five million volts. Instead of altering one-tenth per cent., let the speed vary 1 per cent., the pressure falls to half a million volts.

IMPROVED MOULDING MACHINE.

The accompanying illustration represents an improved form of sand moulding machine (Woolnough & Dehne's patent) manufactured by Messrs. Samuelson & Co., Limited, Britannia Works, Banbury. The machine consists essentially of two vertical columns resting on a bed-plate, the distance between which is capable of adjustment according to the size of the pattern plate. In the columns are two spindles which carry the pattern plate in bearings, and are raised and lowered in the columns by means of a hand lever. The pattern plate can be turned completely round in its bearings, and the moulding boxes can be firmly attached to it by means of split keys or screws. The bottom box is first fixed to the plate and the sand rammed up; the whole is then turned completely over and the box lowered until it rests upon the table; the plate is then unfastened from the box and fixed in its bearings by the set screws, and, by means of the hand lever, is raised from the mould. This operation leaves the bottom box ready for use. The process of moulding the top box is exactly the same as for the bottom, taking, of course, the impression from the other side of the plate.

The makers claim that the accurate vertical lift and the raising of the pattern plates equally on both spindles prevents the breaking off of the corners or the cracking of the sand, thus completely avoiding the troublesome application of water and the "mending up" of the mould. The construction of the lift, we are informed, is so accurate that little or no taper is required in the pattern, an advantage where a deep lift is necessary. It is further claimed that the joint is accurately made, that no fin is left, and a highly finished surface is obtained by lifting the pattern from the sand by means of the hand lever, dusting the mould with blacking, and replacing the pattern in the mould; by this means the surfaces are easily and rapidly sleeked and made exceptionally smooth. A labourer can work the machine, as beyond ramming up the sand no skill is required.

THE PROGRESS OF ELECTRICAL ENGINEERING IN 1890.

I.

The year which has recently closed has, perhaps, been the most active that electrical engineering has yet seen. Nearly every firm has been so busy that work has been considerably behind promised delivery. Many of the electrical works have resorted to overtime, and considerable difficulty has been felt in getting skilled labour in various departments, owing to the general briskness of work.

Perhaps the most important event of the year was the opening of the City and South London undergronnd electrical railway. This is remarkable, not so much for any new departure in electrical engineering—as there are no special novelties in the design—as for the perfect confidence deservedly shown in electrical engineering. Not only is this railway an important piece of electrical engineering itself, but it will, doubtless, be the beginning of a general waking up to the knowledge of the fact that the electrical engineer can actually handle the transmission of power—even of large powers—very much better than is commonly supposed. Electrical engineers are so accustomed to look upon the transmission of power as perfectly easy, that they are apt to forget that the ordinary mechanical or civil engineer does not yet fully realise what an electromotor is.

Central Stations.

The growth of central station supply during the last year has been most remarkable. The Deptford Station has been advancing slowly, but surely, towards completion. The engineers have had, as might be expected, to deal with many unforeseen difficulties; and, as might also have been expected by those who know the engineers, the difficulties have been met with skill, courage, and dogged perseverance.

The various London companies have been rapidly developing their business. As a rule the demand for lamps has exceeded the supply, and the field for central station work seems to be unlimited.

The Metropolitan Supply Company have been developing their various stations, and gradually increasing their output.

The Notting Hill Electric Light Company are not yet supplying current, but soon will be. Most of the mains have been laid, and the first of their stations is nearly complete.

The West Brompton Central Station, belonging to the House-to-House Company, has been increasing its output, under the able management of Mr. Hall. Mr. Hall has now been succeeded by Mr. Gay, who has recently been identified with Brighton.

The Kensington and Knightsbridge Electric Light Company have been putting down more plant, including four large Gramme-wound dynamos by Crompton & Co. Their new switch board is in working order, and the bare copper strip conductors are giving the greatest satisfaction. According to Mr. Miller, the engineer, the lamps fixed number 25,000, and the output is about 300 kilowatts as a maximum.

The Westminster Electric Supply Corporation now have a permanent station at Millbank Street, with four Goolden dynamos of 45 kilowatts each, and two Mather & Platt machines of 112 kilowatts, and a 500 ampere hour Crompton-Howell battery. This station is also connected to a special Crompton-Howell battery placed in the Houses of Parliament, and used for its circuits alone. This station has already reached an output of over 1,000 amperes. This company has a temporary station at Dacre Street, with two 45 kilowatt dynamos coupled to Willans engines and a 500 ampere hour Crompton-Howell battery. These two stations together supply nearly ten thousand 8 c.p. lamps. Another permanent station is in progress in Eccleston Place; two boilers and dynamos are being put down, the chimney is nearly built, and it is hoped the station will be supplying power this month. There is a fourth station in course of completion in Davies Street, and dynamos, engines, and boilers are ready for erection. About fourteen miles of streets have already had mains laid in them. These stations use Babcock-Willcox and Davey Paxman boilers, Willans & Paxman engines; Crompton, Goolden, Mather & Platt, Electrical Construction, and Siemens dynamos; and Crompton-Howell batteries. This company is fortunate in securing Professor Kennedy as engineer-in-chief. Mr. Foster acts under him as resident engineer. The whole of the architecture, which is a matter of no little difficulty, has been in the hands of Mr. C. Stanley Peach.

The Chelsea Company have been fully employed. They use direct current with batteries and a system of automatic mechanisms designed by Mr. F. King. This company have their main station at Draycott Place, and charge three battery stations from it direct, and also employ dynamotors.

The Electricity Supply Corporation have a station near the Strand. They supply direct currents, and already use 600 horse-power.

The St. James and Pall Mall Electric Lighting Company have been one of the most prosperous. Direct currents without batteries are used. The output has already exceeded 4,000 amperes. Babcock boilers, Willans engines, and some very fine Latimer Clark and Siemens dynamos are used. The whole of the electric work is under Mr. S. D. Dobson. They have never yet had a stoppage of supply.

The Brighton Electric Light Company have been struggling against the threatened competition of the Corporation of Brighton, and have adopted the bold policy of cutting off any consumers who will not sign a three years agreement with them. About three-quarters of their customers have agreed to this, so it would seem that their policy may be successful.

The Eastbourne Electric Light Company continue to develop their high-tension alternate current system of distribution, and, like many other companies, find they cannot cope with the demand for light. They are putting down another Elwell-Parker 70-kilowatt alternate current dynamo, and another high-pressure locomotive type boiler. About 5,000 lamps are in use. The mains, as is well known, are all underground, and have given no trouble except at some of the joints, which were rubber-covered and then coated with guttapercha. A few bad joints have since been vulcanised, and Mr. H. W. Wilkinson, the engineer, anticipates no further difficulty. The sliding-scale system is about to make way for a uniform charge of tenpence per kilowatt hour.

The Sheffield Telephone Company have two Mordey alternators in use and Mordey transformers. One dynamo is driven by a Brush engine. The lighting here is of a specially remunerative nature, as it has been mostly taken by shops, so that the dynamos need not run during the day, and full load comes on early in the evening.

The Exeter Electric Light Company have only just begun to supply power. The whole work has been carried out during last year. Two Mordey 75-kilowatt alternators are used, and two Thomson-Houston 30-light arc machines. Two Fowler compound horizontal and two Westinghouse 25 horse-power engines are used. The Babcock & Willcox boiler is employed. Space is left for two more large engines and the necessary dynamos. The wiring is overhead, and where it crosses a street a No. 10 steel wire is arranged above to act as safety guard. The whole is in charge of Mr. T. P. Wilmshurst.

The Newcastle-upon-Tyne Electric Light Company are increasing steadily. The firm have sufficient confidence in electric lighting plant to arrange to supply power at an exceedingly low price. Of course, it must be remembered that gas is cheap in Newcastle, as coal is cheap; but cheap coal does not reduce the price of electric power in anything like the proportion it reduces the cost of gas. Two Robey engines are used, with trip gear of the Corliss type. Mordey dynamos and Mordey and other transformers are in use. The leads are chiefly, if not wholly, underground. Mr. R. C. Jackson is engineer, and he has the benefit of Mr. A. W. Heaviside's extensive experience of underground wirework.

Messrs. Hammond & Co. are carrying out some very extensive central station work in Madrid. They have just completed a central station there of the same type as that at West Brompton, but twice as large. There is a specially good opening for central station work in Spain, for gas is dear.

The Woking Electric Light Company opened their station on the 1st of November. Kingdon dynamos are used, and hedgehog transformers. Some of the leads pass under a river, and the Fowler-Waring cables stand this strain perfectly.

Fareham was the third town in England lighted wholly by electricity. Overhead wiring is adopted throughout, long poles being used to comply with the Board of Trade regulations. The two chief streets are lighted with twenty-one Thomson-Houston arc lamps, the other streets of the town are provided with 20 candle-power incandescent lamps. Okonite wire is used for the arc circuits. The station has boilers and engines by Messrs. Ransomes, Sims, & Jefferies, which work with great steadiness. The engine is of their 30 horse type, fitted with patent automatic gear. Thomson-Houston dynamos and transformers are used.

The Liverpool Electric Supply Company have, during the last twelve months, increased their supply from six to ten thousand 16-candle lamps. They have now three central stations in operation, and a complete system of underground mains. A continuous supply at 110 volts is kept on day and night. The electric light is very highly appreciated in Liverpool.

(To be continued.)

THE LONDON SMOKE AND FOG PLAGUE:

ITS ORIGIN AND DANGERS, AND A PROPOSED SOLUTION FOR ITS REMEDY.

By B. H. Thwaite, C.E., F.C.S., A.M.Inst.C.E.

I.

One of the most striking characteristics of this mammoth city of London—with its five millions of population—in the eyes of foreigners, is its depressing and sombre atmosphere; an atmosphere that has no parallel, and, it may be safely asserted, one that would not be endured by any other civilised community in Europe. Some of the enterprising citizens of this giant metropolis are ever and anon erecting costly structures, many of them adorned with beautiful and artistic workmanship which for a few months are a joy to passers by, but the destructive atmosphere soon commences its begriming work of defacement, reducing the beauty of stone and marble to a mere caricature of its first and unsullied appearance.

The most unobservant cannot have failed to notice that at early morn, before the workshops are opened, and domestic and restaurant fires are lighted, London has a clear and pure atmosphere occasionally as bright even as that of Paris, and always far more bracing and vigorous, but this clearness is dispelled at the beginning of the clang and clink of hammer and shovel, and the jar and rattle of the wheels of industry and the expedients of domestic work. Why should this be? To ask this is like a cry of interrogation in the wilderness. It should, however, be the duty of every citizen to ask this question and demand an answer, but that which is every one's duty is too often accepted as meaning no one's, and so it is that year after year the same conditions of atmospheric gloom prevail, and year after year architectural beauty is ruthlessly destroyed, and internal art decoration in all its forms is more or less sullied and disfigured, and the labour involved in maintaining domestic cleanliness is enormously increased. But all this inconvenience and the destruction of domestic comfort and the loveliness of art is overshadowed as a damning indictment by the more serious one, which declares that no contagion has a more destructive influence on the well-being and stability of men's lives than the smoke-laden fog of London. Let us analyse the causes constituting this latter characteristic. The sun is the source of life, and under its radiant influence life becomes brighter and all nature is glorious, but the smoke layer intervenes between the dwellers of the metropolis and the solar source of light and life, and this absent invigorator means death for many a delicately constituted life.

How many frail threads of life have been broken by sheer abandonment of effort, because life has no natural stimulus to defeat the effects of nervous depression, God alone knows. "Only a stray sunbeam! Yet it cheered a wretched abode, gladdened a stricken heart." Further, the absence of this external stimulus which the sun gives drives men to seek nervous encouragement in that liquid invigorator which surely destroys, whilst it increases for a transient period, animal and nervous vitality.

A glance at a graphic mortality diagram is more impressive than the mere recapitulation of numerals. It will be seen that a sudden rise of the death line occurs during the period when the full effect of the smoke production of London is more directly felt, or when the barometric change of pressure and the change of temperature produce what is known as the "London fog." The average weekly rate of mortality during the prevalence of fogs is nearly doubled, whilst the deaths traceable to diseases of the respiratory organs are far more than doubled. Of course the effects of the smoke-laden fogs are more marked in the case of persons of advanced age. Mr. E. Hart, editor of the *Sanitary Record*, stated before the Select Committee of the House of Lords on Smoke Abatement and Prevention in 1887, that in a fortnight of heavy fog in 1886 the mortality rose to 40 per 1,000, a rate equal to that of the great cholera year. The fog lately prevailing in the metropolis, although not abnormally dense, gave sufficient evidence of its deadly effect. The mortality rate, which attained the figure of 17·4 for the previous week, rose to 20·5, the average rate of the few weeks before being only 16·6. In more salient figures this means an increase of 269 deaths in the previous week, and of 399 deaths per week on the average of the five weeks. The death record of a single day in the metropolis owing to an ordinary smoke fog may be estimated at between 170 to 200. If a railway accident produced an equivalent disaster, what an outcry there would be for means of prevention and what determined legislative action would follow!

It is the aged who demand our fostering care, and who suffer the most. Their lungs are not sufficiently vital to withstand the combined effects of the frozen aqueous vapour and its accompaniment of sulphur and carbon in

Digitized by Google

atomised form; consequently a lowering of the animal temperature and vitality, followed by a reduction of the work of oxidation of the blood, soon brings the enfeebled life to its close, a life that in many instances is precious to the nation, and often deserving the tenderest care for the good it may have done. The increased weight of the vaporous particles due to the addition of carbon and sulphur increases *pari passu* the specific gravity of the particles of frozen aqueous vapour, and they fall to the breathing level with constantly increasing density, and it is not at all improbable that some day an abnormal condition of the atmosphere may produce such a dense condition of fog as to endanger the lives of all those who are unfortunate enough to be enveloped in its deadly embrace.

At present, and as already shown, in London alone during the fog days the increased death-rate is in numbers equivalent to the sweeping away each day of the inhabitants of a rural village, but even this serious death number in such a vast collection of mortals is not more noticeable than the removal of a cartload of sand from the sea shore.

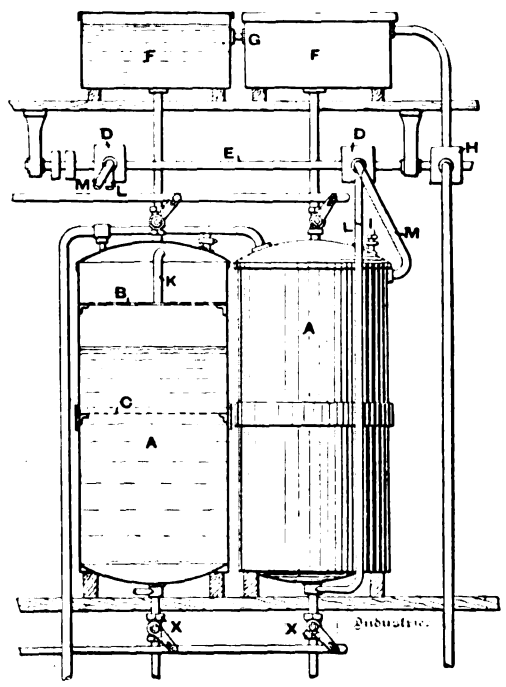
Besides the killing effect on the lives of men traceable to the London smoke fog, there is its destructive effect on the moral stamina, an effect unfortunately not so easily measurable, except by the increased cases of drunkenness during the fog days. "Cleanliness is next to Godliness"—so said sturdy Charles Wesley. It is proved beyond question that this law has an inverse application, and that dirtiness is akin to devilishness, and that the darker and dirtier and more smoke-begrimed the parts of a city, the greater its proportion of crime in proportion to the population. The smoke, grime, and dirt attributes of a great part of London town are in a great part due to the smoke-laden atmosphere, which is the indirect cause of an untold number of crimes and of misery, and it is a black plague of as destructive a character as that London Plague of 1666.

Some salient figures may demonstrate the physical proportions of this modern London plague. A scientist who has given considerable attention to the subject calculates that the daily fog hanging over London weighs 300 tons, 50 tons of this amount being carbon and 250 tons hydrocarbon. This, converted into sterling value, is equivalent to an annual loss of £2,000,000 sterling, or, in other words, London citizens pay £2,000,000 sterling for the privilege of possessing this deadly and daily accompaniment of their lives. What a satire on our industrial, scientific, and sanitary progress!

The principle of the conservation of energy is in no instance more profoundly or more impressively expressed than in the connection between the animal and vegetable world, and the intermediate action of oxidation which is involved in this connection. In animal life the oxidation of the carbon produces carbon-dioxide, the carbon of which is absorbed by the leaves of the vegetable elements. The oxygen is returned to the atmosphere, to be again absorbed by the animal world; the carbon and nitrogen forming the structure of the plant or vegetable is also absorbed in fruit form by the animal world, which gives these elements back again to the vegetable and plant life, the carbon in gaseous form as carbon-dioxide, the nitrogen in liquid form as ammonia or in solid form as nitrogenous matter. In the flame combustion of the vast stores of coal once constituting primeval forests the same action of oxidation goes on as if the vegetable elements had been consumed by animal absorption; and if the flame combustion was as perfect as it is by the animal action, the result of this combustion would be the separation of the nitrogenous results from the carbonaceous ones, and both would be separated for fertilising the vegetable world in a liquid, solid, or gaseous condition for the ultimate benefit of animal life. Thus the two lives, animal and vegetable, are dependent upon each other for mutual continuance of existence. To realise the full majesty of animal life one has to see the jungles of the equatorial forests, where the two kinds of life in magnificent proportion mutually foster each other; but are these natural conditions of mutual interchange in existence as they should be in our artificial methods of life? Our modern Babylon has not the wondrous hanging gardens of its mighty and ancient prototype. Yet London was not always the city of sombre hue; not very many years ago prize roses were grown in Camberwell. That colour of all others so natural and refreshing to human eyes, the verdant green, in all its lovely varied tones and shades, cannot now be seen in London in its pristine purity; a dirty caricature of the exquisite hue is all that can be seen. It is indeed strange that even this parody of natural beauty of colour exists. Nature, however, is so persistent that if there is a vestige of chance it is taken.

In place of the gaseous form of carbon-dioxide and the collected nitrogen, the products of our combustion arrangements in the metropolis are constituted partly of an oxidised and gaseous character such as carbon-monoxide and carbon-dioxide, and partly of carbon in a solid form, in an atomised or finely divided condition as soot or smoke, the nitrogenous and sulphurous constituents of the coal being partly drawn off as ammonia vapour and sulphurous acid, and atomised sulphur. The carbon and sulphur atoms are deposited either on the surface of buildings, destroying their architectural beauty and depreciating their value, or it settles on the leaves of plants, choking up their pores and impeding the natural series of connecting inter-actions that unite the animal and vegetable world.

The carbon in its partially oxidised condition as carbon-monoxide is a gas of combustible value, inodorous and poisonous to organic life. This gas is the intermediate constituent between atomised carbon or smoke and the carbon-dioxide of perfect combustion. Had the carbon-monoxide another equivalent of oxygen it would be in a condition suitable for assimilation by the vegetable world, but, minus this equivalent, it is actually destructive of both vegetable and animal life. Another constituent of our imperfect methods of combustion is carbon-bisulphide, a most obnoxious compound, and one that is responsible for damage to articles of value and silver plate.



The nitrogen constituent in its combination with hydrogen as ammonia vapour forms no inconsiderable proportion of the products of imperfect methods of using fuel, and this valuable fertilising agent is lost in that great inter-action involved in the mutual work of sustenance proceeding between the two forms of organic life. The nitrogen is, however, far from lost in its ruinous characteristics, and if the measure of its baneful action could be taken a surprise would be in store for our economists and scientists.

During the lowering of the temperature or barometric reduction the frozen aqueous vapour constituents of the atmosphere provide surfaces for the deposition of the carbon and sulphur atoms, and thus explain the cause of the dark yellow and murky hue of the London fogs. In the country the change of atmospheric conditions produces a white and, in some instances, beautiful mist, which does not so seriously irritate the bronchial tubes and impede the action of the aëration of the blood, but the atoms of carbon and sulphur arising from the imperfect fuel combustion arrest or impede the interflow or diffusion of the gases in the lung action, and produce in the case of a delicate-chested man loss of vital temperature, followed too often by loss of life.

(To be continued.)

MECHANICAL MATURING OF SPIRITS.

There was recently shown at 83, Leonard Street, Finsbury, London, E.C., an apparatus for maturing spirits by subjecting them to the action of compressed air, the spirits, while being matured, being kept in continuous circulation in a highly subdivided state. The object is to produce the oxidation of the essential oils in the spirits, and to promote their conversion into their ethers.

We illustrate above the apparatus employed. The system consists of a closed cylindrical vessel or vessels A, having a perforated partition B, and a lower partition of wire gauze C. This vessel is charged with the liquor to be treated, and compressed air, after being filtered through water, is admitted by a suitable pipe. The taps having been closed, the liquor is, by means of rotary pumps D D on the shaft E, taken from the bottom by pipes L and forced into the top of the vessel by the pipes M, and is kept in constant circulation, passing down through the perforated partition B in the form of a fine shower. When it falls on the gauze partition C it is broken up into spray, each portion of which is acted upon by the compressed air. The compressed air rises through a pipe K and collects in the top of the cylinder above the liquor, so as not to interfere with the steady flow of the shower, and a slight circulation of the air is thus also effected.

At the end of the process the liquor is run into casks from the taps X X, and the air remaining is allowed to escape by the cocks I.

The liquor can be supplied either direct from barrels or casks, as is the case in the plant shown, or reservoirs may be used as shown at F, connected at a given level by pipes G, and filled by a rotary pump H. The Mechanical Spirit Maturing Apparatus Company claim that by this method they can, in twenty-four hours, effect similar results upon spirits which are otherwise only brought about by keeping them in casks for ten years.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

On Monday, the 5th inst., a paper was read by Mr. Percy C. Gilchrist, on "The Basic Process as Applied to Copper Smelting," in which the author gave details of the experiments which he undertook with the endeavour to obtain similar advantages in copper smelting to those which had resulted from the replacement of the ordinary silicious linings of steel melting furnaces by a lining composed of basic material, and now well known as the author's basic steel process. The two processes are not, however, identical, as in ordinary copper smelting with acid-lined furnaces the loss is due to the formation of copper oxide and its removal in the slags rather than to the incomplete removal of arsenic and antimony from the metal. It was, therefore, rather in the direction of lessened oxidation, and therefore increased yield, that the author expected improved results by the use of basic linings and more calcareous slags in copper smelting.

Arsenical metallic bottoms, however, are advantageously converted into blister copper containing less than 1 per cent. of arsenic by the use of basic roaster furnaces. The removal of the arsenic is accompanied by a largely increased yield of "blister," and there is a further advantage, that the bottom of the furnace when basic-lined does not wear away with the same rapidity as when lined with sand. A very considerable gain in output is also obtained when white or "pimple" metal is treated in a basic roaster furnace, being in some cases as much as 34 per cent. in favour of the basic process. Analyses of various samples were cited to show that there is no practical difference between the refined copper produced from the basic blister and that produced from acid blister when an acid-lined refinery was used. When making ordinary tough cake, however, it is doubtful whether the extra cost of the initial basic lining and of the current repairs are compensated for by the slightly increased yield, but the saving in making "best selected" copper from ordinary arsenical blister is considerable. The basic refinery has hitherto been used chiefly for making best selected copper from B. S. precipitate only, but pure blister or blister containing 1 per cent. of arsenic also yield good results. The most important applications of the new process seem to be that of working down blister rather high in arsenic into B. S. ingots and the treatment of highly arsenical material tapped from the smelting furnaces.

In the discussion which followed several speakers expressed regret that engineers were in the habit of limiting, in their contracts, the percentage of arsenic to be allowed in the copper for ordinary work, although at present no data were available for proving that the presence of arsenic in small quantities was injurious, except when used for electrical purposes. Professor Roberts-Austen also pointed out that the removal of bismuth from copper was essential when used for gold coinage, and expressed the opinion that probably copper might exist in different modifications similar to Osmond's α and β forms of iron.

In replying Mr. Gilchrist pointed out that the high price of copper rendered the question of yield of greater importance than time and labour, and that the loss attending a Bessemerising process applied to copper smelting would probably be too high to make the method economical. Open-hearth steel is rapidly becoming as cheap as that made in a converter, and if this is the case with steel, an open-hearthed basic process will, no doubt, soon become general for copper smelting.

THE PROGRESS OF CHEMICAL INDUSTRY IN 1890.

It is impossible so early in the new year to produce the annual statistics which summarise the progress of the various chemical industries during the past year, although many returns which have already come in might warrant our giving an approximation of the actual figures which will soon be presented to the public. Notwithstanding the absence of the official returns, it is possible to survey the work of the past year and contrast the position of the several industries with their previous records in this and other countries. We do not, however, anticipate that there will be any serious complaints from any of the more important chemical centres when the accounts for the year are balanced, as the Board of Trade returns clearly show that the industries to which we refer have fully maintained their position in this country, and that English manufacturers, with some few exceptions, are still able to compete successfully, not only with the German chemists, but with those countries which produce the raw materials upon which the more important chemical industries are dependent. The increase in the volume of trade which is indicated in nearly every direction is not, however, an index of the profit which has fallen to the several undertakings. The rise in prices which took place in the latter part of 1889, and which has, for the most part, been maintained during the past year, has been to a great extent counterbalanced by higher wages and the increased price paid for raw materials and fuel.

We believe, however, that the statistics for the past year will show that there has been a slight falling off in the value of raw materials used in the chemical industries and imported into this country; and this might indicate a diminution in our manufacture, were it not for the fact that we have during the same period exported chemicals and medicines of greater value than for 1889. The diminution in the value of the imports of raw material for the production of chemical products will therefore probably point to the fact that manufacturers have found it to their interests to discontinue the production of those articles which yield only a small return on the capital invested, and have restricted their operations to the manufacture of goods which are more remunerative and fetch higher prices in foreign countries. Our imports of finished chemicals and dyestuffs are also likely to be less for 1890 as compared with 1889, and here again we do not think we have cause for alarm, as in many directions we find that the English manufacturer is successfully competing with his foreign rivals, and the diminution in imports may therefore be attributed to the public beginning to realise that English productions are equal in all respects to German imported goods.

In the alkali industry, the event of the year is the formation of the union of chemical manufacturers under the title of the United Alkali Company, to control the price and output of alkali, hydrochloric acid, and bleaching compounds. The capital proposed for this undertaking was £8,500,000, but considerably under this amount was subscribed. About fifty of the leading firms are directly interested in the success of the scheme. Practically the whole of the Leblanc manufacturers have joined the new company, and their several businesses are to be concentrated and arranged so as to save the cost of transit from distant parts of the United Kingdom by completing orders in those districts which are nearest to the buyers. We have on more than one occasion expressed our views on the disadvantages to trade which combinations of this character usually produce, and whilst the collapse of the copper "ring" is still fresh in the memory it is surprising that any new venture on a similar scale should be again attempted. We are told that the Union does not aim at inflating the prices of the chemicals which they control higher than those which will secure their combination a fair return for the capital invested, but we are glad that the majority of the investing public have refrained from putting their money into the new union, mainly on the ground that, although it may be true that the works and plant acquired cost what is stated, little attention has been paid to the fact that much of this plant has had its day, and that newer processes have been and are being devised which attain the same results by quicker and cheaper methods—the stagnation which has been observable to most people in the larger Leblanc works in the Newcastle and Widnes districts being due in the past, not so much to competition among the rival makers, as to the fact that the Leblanc process has been for some time past on its last legs. Chance's sulphur recovery process and allied improvements can only have the effect of bolstering it up for a time, and as bleaching powder is gradually replaced by improved methods of bleaching with sulphite, oxygen, ozone, hydrogen peroxide, or by the electrolysis of chlorides, the new union will find its dividends gradually diminish, and its works one by one require dismantling. In the Articles of Association, however, the company is described as formed to carry on most industrial enterprises connected with chemistry, electricity, and engineering, so it is possible that the company may, by turning its attention to fresh fields of enterprise, succeed in utilising the properties acquired when they cease to be remunerative as bleach or alkali factories.

The monopoly caused by the formation of this union has naturally affected the prices of the commodities which they produce. It will be remembered that bleaching powder was at about its lowest figure—viz., £4 12s. 6d. to £5—in December, 1889, and during the earlier part of last year it remained at about £5. In September the price had increased to £5 10s., and during the last month it has risen to £6 10s. and £7, and is now not far short of the price that was ruling in 1888. In soda ash and caustic the rise in prices has been still more marked. In January, 1890, 70 per cent. caustic was quoted at £7 2s. 6d. per ton; in March, £8 10s.; in June, £8; in September, £10 17s. 6d.; and in December last, £11 5s., with a tendency to go higher. This value is nearly double that of two years ago, and is far in excess of the legitimate increase due to increased value of sulphuric acid, salt, coal, and labour. Soda crystals also show an increase of nearly 50 per cent. in price, from £2 7s. 6d. to £3 5s., and bicarbonate a gradual rise from £5 to £7 per ton.

We have little to record with regard to improvements in manufacture. The Chance's sulphur recovery process, to which we alluded in our last annual report, has fully maintained its reputation, and there can be little doubt that so long as the Leblanc process exists it will be found a valuable adjunct in its economic working. The sales of recovered sulphur during the year have been steadily increasing, but the new United States tariff of eight dollars per ton is likely to seriously interfere with the "Union's" export trade to that country. In a recent issue we have drawn attention to a new chlorine process devised by Wilde and Reychler, which bids fair to replace the Weldon and Deacon methods of working, but which, as we have already pointed out, requires additional plant, and is, therefore, unlikely to be employed by the Union so long as their monopoly lasts. It is not easy to predict what effect the combination will have upon our export and import trades. In the time of the Bleach Association in this country, the high price of bleaching powder did good service to our German competitors, as it enabled them to partially counterbalance their losses on alkali, and now that the price has again an upward tendency it seems probable that the German manufacturers will once more benefit at our expense. The bleaching powder now being made from the Stassfurt magnesium chloride will probably find a market in this country, and as Stassfurt potassium chloride is also being used by an electrolytic process to furnish an additional source of bleaching powder, which is already in the German market, there is an additional ground for believing that manufacturers will have to face German competition. In any case, the fact that Germany is now producing bleaching powder from these sources will tend to diminish our exports to that country. In 1887 Great Britain sent to Germany 2,978,700 kilos. of bleaching powder; in 1888, 4,081,900; and in 1889, 3,391,000, showing that our export had already begun to diminish, even when bleaching powder was selling at £5 per ton, and we imagine that the past year will show a further shrinkage, and it is not unlikely that, with the Union prices, Germany will refuse to buy any of this commodity from us during the current year. We believe that bleaching powder and the allied products will, therefore, fall into the same category as aniline dyes, tar colours, alizarine, ultramarine, white lead—viz., chemical industries which were formerly English, but from various causes have, of late years, shown a distinct shrinkage in this country, and an increasingly greater German import. It is interesting also to notice that, although the alkali products already mentioned have risen in price, chlorate of potash has not altered in value, notwithstanding the fact that this country is almost the only producer of this compound.

The ammonia soda process may be credited with about one-half of the world's production of alkali, and at the present time there are six Solvay works in operation in this country, and Messrs. Brunner, Mond, & Co.'s, at Northwich, still stands ahead of the German and French firms. In England, as pointed out by the Chief Inspector of Alkali Works, the proportion which falls to the ammonia soda process is gradually becoming larger. In 1887 it commanded 21·55 per cent. of the trade; in 1888, 26·60 per cent.; and in 1889, 27·29 per cent., whilst the year just ended is expected to show upwards of 30 per cent. The following table shows the amount of salt decomposed by both processes in the United Kingdom:—

	1884.	1885.	1886.	1887.	1888.	1889.
Leblanc process.	578,874	598,096	584,323	577,381	585,498	584,203
Ammonia soda	89,759	115,032	137,220	158,636	212,181	219,279
Total...	668,633	713,128	721,543	736,017	797,679	803,482

The production of sulphate of ammonia is also rapidly increasing, and offers a partial explanation of the maintenance of the price of sulphuric acid notwithstanding the increased imports of pyrites and the development of the Chance's recovery process. We find that 113,896 tons of this fertiliser was manufactured in 1887, 122,785 tons in 1888, 133,604 tons in 1889, and about 150,000 tons for the year just completed. Farmers in this country still allow the great bulk of this fertiliser to be exported to France and Germany, where it finds favour with the beet-root sugar producers. Its price, however, has not been maintained during the year, as a ton brought in the spring upwards of £12, and at the present time only about £10 10s.

The nitrate industry, as we predicted in our last annual report, is now suffering from the folly of over-production, and the several companies have within the last few weeks determined to follow the example set in other industries similarly situated, and have agreed to combine as far as possible with a view to restrict the output. All the English companies have intimated their adhesion to this scheme, and if the local producers can be induced to join the combination, the "ring" so formed will shortly be in a position, if it so desires it, to create a famine in this particular article of commerce. Although the chief use of nitrate is that of a fertiliser, and as such has to compete against sulphate of ammonia in price, 30 per cent. is consumed in the manufacture of nitric acid, nitroglycerine, dynamite, and gunpowder, so that a rise in price would seriously affect several lesser industries.

The following table shows the consumption and shipments in tons during the last three years, ending with December:—

	1888.	1889.	1890.
Consumption.....	694,000	750,000	885,000
Shipments	764,000	930,000	1,028,000
London spot price on Dec. 31st, per cent.	11s.	8s. 4½d.	7s. 7½d.

The production of salt in the United Kingdom is so intimately connected with our chemical industries that we must note in passing that the Salt Union, whilst maintaining the price, has not secured the additional trade which it expected. The relations of our trade to and from Germany in this commodity illustrates in a striking way the advantages and disadvantages of a control in one commodity. Our exports to Germany show a falling off, as follows:—

	1887-1888.	1888-1889.	1889-1890.
Tons	24,072	25,265	22,741

Whilst in Germany, where a combination also exists, but apparently is managed so as to develop trade, we find that the home trade is supplied more completely with the home produce, and prices admit of a development of the export trade.

German Salt Statistics.

	1887-88. Tons.	1888-89. Tons.	1889-90. Tons.
Inland consumption of home manufacture ...	722,314	734,623	770,850
Export	125,748	134,171	192,258

The German Stassfurt potash salt industry is also making slow but steady progress, notwithstanding the falling off in the consumption of potassium nitrate owing to the introduction of the "smokeless" gunpowder. The syndicated manufacturers now include eight of the leading firms, and amongst the number is the German Solvay Company in Bernburg. About a year ago additional works were opened at Thiede. Prices, for the most part, have been maintained during the year, although potassium chlorate, as already mentioned, is still exceptionally low. Amongst improvements in manufacture it may be mentioned that the Engels patent for the preparation of caustic potash by means of magnesia is now being worked at the Salzberg works at Neu-Stassfurt.

The space we can give to this review does not usually admit of our noticing the year's progress in metallurgical chemistry. We have from time to time drawn our readers' attention, in our "Notes on Alloys," to the rapid progress which is being made towards establishing the physical behaviour of the various compound steels which have recently been introduced, and Osmond and Roberts-Austen and their co-workers have left on record for the present year valuable information, which, although at present, perhaps, of only scientific interest, cannot fail in the near future to have an important influence upon our larger metallurgical industries. The Annapolis trials of nickel steel for armour plating, and the great public interest shown in the United States and this country, has brought nickel prominently to the front as one of the most important metals for this special use, and the discoveries at Sudbury, in Canada, warrant the belief that in time the complex minerals which abound there may be economically reduced, and so afford an abun-

Digitized by Google

dant supply of this valuable element. The patents for the making of nickel steel are now in the hands of a syndicate in this country, and we understand it has also secured the more important nickel mines in which the ore is in an easily worked condition. The syndicate does not propose to manufacture, but to grant licences to existing steel masters, so that for the present, at any rate, there will be no impediment towards a rapid development of the use of this new material. There is little new to record concerning aluminium. Glowing accounts have, however, reached this country of the perfection of the electrolytic production of this metal by the Pittsburgh Reduction Company. The success which has attended this venture seems to be due to the happy thought of employing a mixture of cryolite and fluor spar, or triple fluoride of aluminium, sodium, and calcium, as a solvent for the alumina to be electrolysed. Aluminium cast ready for rolling is made by this process at less than ½ dollar per lb., which is considerably lower than that made by any of the rival processes. The works at Pittsburgh were started in 1888; in 1889 they were turning out 50lb. per day; in 1890, at the time of the visit of the Iron and Steel Institute, an average of 375lb. per day; while during the present year the company will have ready plant for making five tons per day. In a recent issue we drew attention to the scarceness of the metal platinum, and pointed out that the growing demand for this element for electrical work has induced fresh capital and energy to be thrown into this old-fashioned and steady-going mining industry.

The Russian naphtha industry has had a highly satisfactory year, and both the production and export of Baku oil products continues to grow. During the first five months of 1890, according to the report of the Russian Minister of Finance, 22,720,000 poods of naphtha were exported, or 7,560,000 more than in the corresponding period of last year. The Wladikawkas-Baku railway is in process of completion, and a further important development of this industry is expected to ensue therefrom. The Rothschilds are also erecting at Baku works for the manufacture of benzole from naphtha residue, owing to the success which has been experienced in the manufacture of benzene and anthracene at Schibajeivs oil works in the same district. In Galicia, where the industry has been stagnant, American tools have been introduced for boring with considerable success, and it is hoped that capitalists will now be induced to further the development of this industry. Reports from Peru announce the discovery of very important petroleum wells in the department of Poina, which will, it is hoped, be the means of creating a new source of prosperity for that country.

In gaseous fuels we notice that the gas companies are giving serious attention to the utilisation of carburetted water gas as an adjunct to their several enterprises. The excitement over the water-gas question having abated, it has been demonstrated that, although alone it can only have a minor and local value, yet when converted into an illuminant it can furnish a gas of higher illuminating power than that furnished by ordinary coal, and as an "enricher" is more economical than the employment of cannel coal for the purpose. The incandescent lighting at Harrogate was discontinued in the autumn of last year owing to several causes, but we imagine that such a method of utilisation, although unsuccessful at present, may eventually be adopted, as it would obviously be of advantage that the same supply pipes should furnish the consumer with a source of heat which could be also utilised for lighting purposes. A very exhaustive *résumé* of the present position of gaseous illuminants in this county has recently been given by Professor Lewes in the Cantor Lectures at the Society of Arts, to our reports of which we must refer our readers.

In oils and tar products the past year has been marked by steady trade and little alteration in prices. The coal tar colour industry in this country is still in a low condition, owing to the keenness of German competition, where higher profits, due chiefly to increased production, have been obtained. The progressive nature of the German industry is shown by the following average dividends of the leading firms:—

1885.	1886.	1887.	1888.	1889.	1890.
7·05%	9·94%	13·25%	15·44%	17·50%	19·00%

These profits, however, are not due solely to the colour trade, as most of the foreign firms have combined with their business the production of antiseptics, pharmaceutical preparations, and, in some cases, the manufacture of alkali products. A leading firm in this country has amalgamated with one of the prominent German companies, but we are of opinion that English manufacturers, if they widen their business so as to include photographic and pharmaceutical preparations, will again resume their former position. Many new colouring matters, some of great value, have been manufactured, and especial progress has been made in the chemistry of azo compounds. Dr. Perkin, at the Leeds meeting of the British Association, gave an admirable *résumé* of the present position of this important industry, and Professor Hummell's paper will do good service in removing the prejudice which still exists amongst dyers in this country of using these colouring matters for their work. Alizarine colours have been especially active, and it looks as if artificial indigo will soon be manufactured economically. Dr. Henmann, of Zurich, suggests that the manufacture of this dyestuff can be readily executed by first preparing phenylglycocine from monochloracetic acid and aniline, and then treating the product with caustic potash. If this process is successful on a commercial scale, the indigo districts of India are likely to share the same fate as the madder fields of France.

In photographic and pharmaceutical products, although an increasing business has been done, and the influenza epidemic gave a heavy demand for quinine, antipyrin, phenacetine, and antifebrin, yet the higher prices for raw materials, and the keenness of competition in these branches of technical chemistry, have prevented manufacturers from realising the large profits of a few years ago. The manufacturers of pharmaceutical substances and allied chemicals have been but slightly affected by the McKinley Tariff Act, and on many substances the duties have been reduced. The principal reductions are those on tannic acid, refined camphor, chloroform, nitrous and sulphuric ether, glycerine, iodine, iodoform, morphia, strychnine, several potash salts, whilst mercurials, phosphorus, and chromates have been increased.

The Inland Revenue report draws attention to the increased consumption of methylated spirit in this country, 3,188,306 gallons having been consumed in the official year, or 227,402 gallons in excess of the previous twelve months. Considerable agitation still exists in Germany as to the desirability of the Government allowing manufactures duty free pure spirit, and there can be no doubt that in Great Britain such a "drawback" would be an immense boon to pharmaceutical chemists and to many industries in which this article is required.

The manufacture of inorganic colouring matters is making good progress in this country, although there appears to be room for improvement and development in many of the minor colours. We have previously urged that attention should be paid to the manufacture of ultramarine in this country, and we believe that if the energies which are now being devoted to white lead and its manufacture were diverted to other channels, many of the inorganic pigments would offer a remunerative investment.

Our space does not permit us to more than point out that the soap industry in this country still maintains its important position, and shows signs of still further development. The manufacture of explosives, to which we referred at some length last year, is undergoing a great change, the new smokeless powders and various forms of "nitro" compounds in use for blasting purposes having almost entirely replaced the old-fashioned gunpowders containing sulphur and potassium nitrate. Many of the companies have done good work during the year, and have proved the efficiency of their products for special work; but time and further research alone will differentiate the good from the bad, and decide what compositions are likely to have a long future.

Notes.

TRADE AT PANAMA

A Foreign Office report states that business at Panama is in a stagnant condition, owing to the stoppage of the canal works. Many firms have been compelled to close, and others have become bankrupt. Many improvements have, however, been carried out during the past few years. An electric lighting company, having a concession from the authorities of the town of Panama, has started operations, there being 43 arc lamps for street lighting and 300 glow lamps in houses. A tramway is under construction, and a waterworks company has been organised. At the town of Cartagena two tramways have been built on the Decauville system. A contract has recently been made with an American syndicate to connect Cartagena with the River Magdalena. Another syndicate proposes to build a railway from Cartagena to Cucuta.

SPARKLESS ELECTROMAGNETS.

Among the numerous points of interest in Professor S. P. Thompson's Cantor Lectures on "Electromagnets" is a discussion of sparkless electromagnets. Among these he mentions the double-wound, or differential, electromagnet. This, we believe, was invented by Dr. Thompson himself, but the theory given seems inaccurate. According to the learned lecturer, there is no spark on making the circuit because the magnet is magnetised already, and none on breaking because there is then no magnetism. This is inaccurate, because the spark does not depend on the magnetism, but on its rate of change. If the current in the second wire were kept constant, there would be a spark on breaking the first. As it is the second wire acts as a secondary, and the current in it is reduced by the increasing magnetisation. If a second single-wound magnet were put in this second circuit, so that any variation of the current would be opposed by its self-induction, a spark would be produced on breaking the first circuit. A simple and effective way of making a sparkless electromagnet is to put some voltameters, made of lead plates in dilute sulphuric acid, in shunt to the break. These act as condensers of enormous capacity, and run down completely on short circuit. Professor Thompson is, apparently, writing an exhaustive historical and practical encyclopædia of electrical engineering. The articles on dynamos, transformers, arc lamps, influence machines, telephones, mercury pumps, storage batteries, and electromagnets are now complete. We wait for those on primary batteries, permanent magnets, incandescent lamps, central stations, steam engines, chimney construction, boilers, and a few minor subjects.

EMIGRATION TO THE COLONIES.

In a circular issued from the Emigrants' Information Office, 31, Broadway, Westminster, S.W., it is stated that there is no demand in Canada for men during the winter. Emigrants should not arrive before April, when there is likely to be a demand for farm hands, carpenters, masons, and others in the building trade. Female servants are always in demand. The chief demand in Australasia is for female servants, farmers, miners, navvies, farm hands, dairymen, ploughmen, gardeners other than fancy flower gardeners, bushmen, general labourers, and men who are well up in working land, pruning fruit trees, shearing, and nursery work. Such men and women will, under certain conditions, get free or reduced passages to Queensland and Western Australia. There is no demand for mechanics in Queensland, South Australia, or New Zealand, and but little in the other Australasian Colonies, though the general strike is now over; but good workmen will generally find employment. In South Africa carpenters, masons, bricklayers, and other useful mechanics, navvies, farmers, men accustomed to work on the land, and female servants are in demand in Cape Colony and Natal, and may, under certain conditions, obtain reduced passages there.

THE COTTON TRADE.

The results of the quarterly stocktakings of the twenty-three joint-stock cotton spinning companies given below are considered encouraging. Most of the companies have declared dividends to the extent of 10 per cent., and carried moderate sums forward to reserve funds. The prospects of the trade are, on the whole, favourable, but the margin between yarn and cotton is not quite so wide as a fortnight ago, for cotton has recently advanced ⅛d., and yarn has not moved upward at all. At present there are eighteen cotton mills in course of erection. These mills will hold 1,315,000 bales. American cotton crop estimates are again to the front, the *Financial Chronicle*, of New York, having given out 8,000,000 bales as the probable yield.

QUARTERLY STOCKTAKINGS.

	Capital.	Spindles.	Profit.
Moorfield	£73,693	£72,036	£1,131
Clough	40,743	42,656	840
Astley	101,184	84,024	1,325
Quickedge	35,726	29,868	203
Guide Bridge	170,890	150,240	2,400
Staleybridge	81,556	75,420	1,320
Milburne	49,000	63,528	400
Longfield	52,160	20,760	256
Equitable	84,200	78,780	1,152
Albert	42,041	22,262	345
Dowry	70,682	66,760	1,514
Duke	84,548	70,380	1,547
Grosvenor	7,966	11,220	189
Oak	119,226	109,362	1,531
Ivy	46,556	34,656	750
Parkside	47,830	49,194	1,395
Ridgefield	104,526	69,072	1,267
Rochdale	81,551	70,672	1,615
Royton	63,280	68,436	955
Stanley	64,845	48,480	501
West-end	117,000	118,540	2,100
Hollinwood	75,024	75,024	1,257

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

22nd December, 1890.

18869A. Gutensohn, A. ..... Apparatus for preparing metal plates for annealing and for coating with tin or other metal. (21st November, 1890.)

27th December, 1890.

19370A. Scholes & Scholes ... Self-measuring and registering taps. (28th November, 1890.)

22nd December, 1890.

20849. Dickson & Kilburn ... Milling machines for textile factories.
20851. Smith, D. W. ..... Shuttle checking appliances of looms.
20854. Cooper, J. ..... Slide valve.
20855. Frew, J. ..... Equilibrated valves.
20856. Reid, W. ..... Looms.
20863. Quéry, F. ..... Machinery for the manufacture of earthenware pipes.
20867. Williams, P. H. ..... Turbines.
20872. Pearsall, H. D. ..... Meters.
20874. Pearsall, H. D. ..... Hydraulic rams.
20880. Lilleyman, G. ..... Ejector mechanism of drop-down guns.
20881. Mellor, T. K. ..... Excavating machines (*Mahlstedt*).
20882. Lake, H. H. ..... Axle lubricators (*White*).
20883. Meyer, C. ..... Lubricator for steam engines.
20888. Holt, H. P. ..... Gas, oil, or other vapour engines.
20899. Bucherer, J. M. ..... Rotary engine.
20901. Holthaus, W. ..... Jacquard and similar looms.
20902. Wells, C. ..... Steam engines.

23rd December, 1890.

20913. Thom, J. ..... Steam engines.
20943. Keats & Keats ..... Rotary cutters.
20947. Konegen, W. ..... Horizontal bolting mills.
20953. Hambelton, W. F. ..... Safety railway carriage coupling.
20957. Boult, A. J. ..... Motors (*Larcheveque*).
20961. Gribben, W. ..... Feed regulators.
20970. Wells, C. ..... Combined steam and soda engine.
20971. Gilmore & Clark ..... Liquid meter.
20975. Stark, D. ..... Feed water heater and purifier.
20988. Fowler, C. W. ..... Elevators. (13th August, 1890.)
20990. Dasher, H. D. ..... Railroad ties. (14th August, 1890.)
20993. Hewett, E. ..... Oscillating slide-valve for steam cylinders.

24th December, 1890.

20994. Barnett, H. T. ..... Hot-air engines.
21002. Richards, G. ..... Single-acting engines.
21005. Fairweather, W. ..... Automatic stokers (*Pratt & The Babcock and Wilcox Company*).
21010. Birch, G. ..... Lathe chucks.
21011. Barker, R. W. ..... Car couplings (*Seley*).
21016. Maw, J. R. ..... Boilers.
21018. Taylor & Challen ..... Power presses.
21045. Walton, F. ..... Apparatus for armouring insulated electrical conductors.
21046. Colebrook, C. T. ..... Packing rings for pistons, &c.
21047. Vernay, C. ..... Machinery for making bottles.
21060. Sheppard, C. ..... Steam pump.
21065. Burrell, F. J. ..... Pneumatic guns.
21067. Gardner, H. ..... Apparatus for surfacing and truing spheres in metal (*Fischer*).

27th December, 1890.

21084. Lejeune, A. ..... Carding machines.
21086. Brüggemann, A. ..... Pulsometer.
21092. Whitfield, C. ..... Machine rollers.
21093. Barr, J. ..... Hydraulic cylinder and piston motors.
21094. Murrie, J. ..... Motive power engine.
21095. Donaldson, J. (of the Firm of J. I. Thorneycroft & Co.) ..... Machinery for bending tubes.
21096. Castelnau, F. M. ..... Ore crushers.
21113. Ingham & Spencer ..... Looms.
21114. Heppenstall, Sykes, & Sykes ..... Machinery for dyeing wool, cotton, &c.
21126. Foord, W. S. ..... Printing machines.
21127. Lake, H. H. ..... Steam boilers (*Platt*).
21128. Hooker, J. ..... Type-setting machine.

29th December, 1890.

21140. Pilot & Jeyes ..... Automatic lubricator.
21145. Allison, H. J. ..... Hydrocarbon injectors for the furnaces of steam boilers (*Jones*).
21155. Deweppe, F. ..... Looms.
21161. Lawson, G. ..... Steam engines.
21163. Boot, J. ..... Loom shuttles and their cop spindles.
21165. Lentz, Czermak, Streitmann, & Bergl ..... Gas engine.
21166. Comings & Righter ... Metal presses.

30th December, 1890.

21176. Lindsay & Lindsay ... Looms.
21187. Burlingham, S. ..... Machinery for pressing bricks, &c.
21201. Royston, E. R. ..... Heat engines.
21218. Neate, P. J. ..... Grinding mills.
21221. Bohm, W. D. ..... Apparatus for the separation of gold and silver from ores.
21228. Ellinwood, A. E. ..... Match-making machinery.
21229. Ellinwood, A. E. ..... Match-making machines.
21231. Ensinger, G. W. ..... Furnaces.

31st December, 1890.

21243. Lake, H. H. ..... Apparatus for heating the feed-water of boilers (*Burpee*).
21252. Sleat & Skelton ..... Compound steam engines.
21268. Gill, D. ..... Ball valves and other water taps.
21271. Laidlaw, J. ..... Mechanical tube scrubber.
21273. Croll & Hohn ..... Steam boiler furnaces.
21282. Haensel, G. (of the German Confectionery Company) ..... Hoists.
21288. Sandwell, W. D. ..... Cranes and other hoisting machinery.
21292. Lane, F. R. ..... Propellers.

ELECTRICITY.

23rd December, 1890.

19272A. Carpenter, C. E. ..... Electric soldering irons. (26th November, 1890.)

22nd December, 1890.

20896. Gay & Hammond ..... Apparatus for regulating electric currents.
20898. Leigh, H. H. ..... Dynamo-electric machines (*Desroziers*).

23rd December, 1890.

20936. Wyckoff, A. B. ..... Signalling apparatus.
20940. Beck, W. H. ..... Indicating apparatus for range-finding instruments (*American Range Finder Company*).
20983. Hurrell, M. H. ..... Electrically-controlled long-range torpedoes.
20986. Lake, H. H. ..... Electrical welding apparatus (*Lemp*).
20992. Jones, G. H. ..... Electric bells.

24th December, 1890.

21017. Protz & Juckes ..... Arc lamps.
21031. Davies, P. J. ..... Secondary batteries.
21032. Horn, W. W. ..... Insulation for conductors (*Oehrle*).
21043. Essick, S. Van B. ..... Telegraphic apparatus.

27th December, 1890.

21116. Gay & Hammond ..... Arc lamps.

29th December, 1890.

21143. Rhodes, O. Y. ..... Batteries for lighting miners' safety lamps.
21147. Boult, A. J. ..... Insulation of electrical conductors (*Frédureau*).

31st December, 1890.

21254. Morris Brothers, Ld. Instrument for measuring electromotive force and current of electricity.
21301. Murday, T. J. ..... Signalling device for indicating the overheating of journals, bearings, &c.

CHEMISTRY.

22nd December, 1890.

20889. Imray, O. ..... Azo colouring matters (*Farbwerke vormals Meister Lucius & Brüning*).

23rd December, 1890.

20966. Stevens, G. ..... Antifouling or corrosive compositions.
20978. Lake, H. H. ..... Manufacture of nitro-cellulose or pyroxylin (*Mowbray*).

24th December, 1890.

20996. Candy, F. P. ..... Method of treating sewage.

27th December, 1890.

21071. Campbell, Boyd, & Kirkpatrick ..... Treatment of crude bicarbonate of soda to obtain caustic soda, carbonic acid, and other products.
21078. Leith, J. ..... Production of bicarbonate of soda and sulphuretted hydrogen.

30th December, 1890.

21205. Peters, T. ..... Red colouring matters.
21225. Lyte & Steinhart ..... Production of chlorine and of hydrochloric acid.

31st December, 1890.

21284. Geigy, J. R. ..... Manufacture of diethyldibenzyldiamidodiphenylmethan disulpho acid and violet dyestuffs therefrom.

MISCELLANEOUS.

22nd December, 1890.

20879. Jones & Jones ..... Obtaining motive power.
20895. Bott, J. E. ..... Manufacture of armour plates.

23rd December, 1890.

20907. Bristol, F. B. ..... Punches and dies.
20944. Elliott, S. ..... Method of condensing lead and other metallic fumes arising from furnaces.
20954. Imray, O. ..... Process for annealing iron plates (*Bang & Ruffin*).
20974. Sellers, G. H. ..... Drills and augers.
20977. Meier, J. ..... Transmitting power.
20980. Beardmore, I. ..... Regulating valves of regenerative gas furnaces for steel melting.

24th December, 1890.

21007. Dickson, A. C. ..... Weaving shuttles.

29th December, 1890.

21142. Rhodes, O. Y. ..... Miners' safety lamps.

30th December, 1890.

21170. Bauer, C. ..... Flexible tubing.
21222. Siemens, F. ..... Reduction of iron ore.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1889.

18929. Hargreaves.
20656. Lock.
19252. Iles.
20773. Wadsworth.
20792. Lusuardi & Falco.
20974. Van Rysselberghe.
20652. John Wigham Edmundson & Margaret Clarke (Executrix of the late William Clarke).
20975. Van Rysselberghe.

1890.

8. De Negri.
141. Gildersleeve & Matthews.
576. Gill.
669. Ballard.

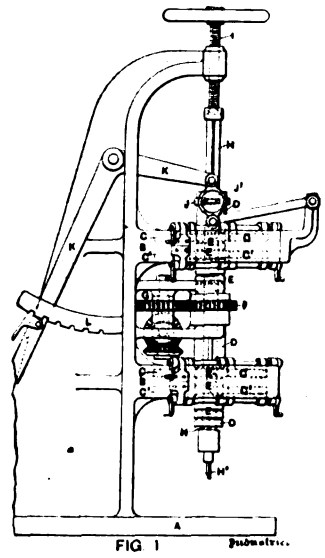
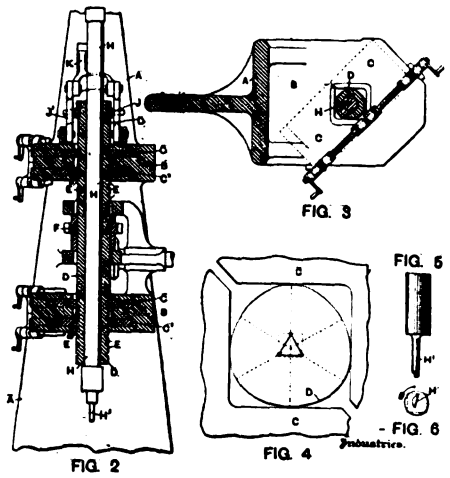
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Steam Engine Slide Valves.—*H. Muncaster, St. George's, Wellington, Salop.*—The inventor relieves the pressure acting on the back of the valve, and thereby lessens the friction on the valve face due to such pressure, in the following manner, reference being made to the accompanying illustrations, of which Fig. 1 is a sectional elevation of a double-ported valve arranged according to this invention, and also part of cylinder, Fig. 2 is an elevation of valve and part of cylinder, Fig. 3 is an elevation of cylinder port face with valve removed, Fig. 4 is a transverse section of valve and part of cylinder. In Fig. 1 A is part of the engine cylinder, of which B are steam ports and C exhaust



port and D the chest under steam pressure. E is a piece firmly bolted to cylinder port face F so as to form a table with a perfectly flat surface G at some distance from and parallel to the said face, and is of such a shape as not to arrest the flow of the exhaust steam through the exhaust port C. The slide valve H is arranged to work over the table piece E, and has a plane surface at I in contact with the cylinder port face F, and of the proper shape to give the required distribution of the steam. To the back of the valve H is fixed a plate J, having an opening K of an area corresponding with the amount of pressure of which it is found desirable to relieve the valve; the said plate has a narrow strip forming a margin to the opening K. This strip provides a surface L in a plane parallel to the valve face I, and at a distance from it equal to the depth of the table piece E, so that when the valve is in working condition the faces F and I are in contact at the same moment as are the faces G and L. Three claims are made, embracing the arrangement as described.—No. 826. January 16th, 1890. 6*d.*

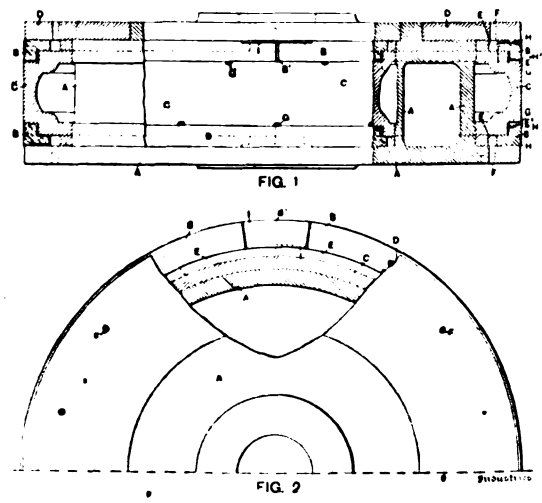


Shuttle Guards for Looms.—*R. Smyth & J. Middleton, both of Tullyelmer, Armagh, Ireland.*—To prevent the shuttles flying out when the loom is in operation, the inventors place a guard bar across the entire reed space, which is carried as follows:—One end of a radius rod at each end of the loom is hinged to the hand rail, and carries at its outer end, at a suitable distance apart, two other radius rods, the opposite ends of one pair of which are hinged to the rocking sword carrying the slay, slay cap, reed shuttles, &c. The opposite ends of the other pair of rods carry the shuttle guard which completely covers the shuttle race, and just touches the yarn when the shade is sprung and the shuttle passing. It then, actuated from the rocking sword, rises and gives the weaver room to regulate the yarn, and is so held while passing over temples and weft forks, and continues to act whilst the loom is in motion. Claims: An automatic shuttle guard with up and down motion at right angles with the shuttle race, and parts for operating same, substantially as described.—No. 20,594. December 23rd, 1889. 6*d.*

Boiler Furnaces.—*A. Jobson, Darlington.*—The invention relates to boilers in which there are internal furnaces, the products of combustion passing out at one end of the boiler into a descending flue and passing along a flue beneath the bottom of the boiler. According to this invention the inventor employs in the bottom flue a supplementary furnace situated at the end where the products of combustion enter, the object being to assist in burning the products of combustion, to increase the quantity of steam raised, and to improve the circulation. In some cases the inventor builds an arch over the supplementary fire or part of it; this arch serves to prevent the products of combustion from immediately entering said fire. Three claims are made, embracing the use of a supplementary fire and arch over same, substantially as described.—No. 1817. February 3rd, 1890. 6*d.*

Square Hole Drilling Machine.—*H. F. Ainley & A. C. Oakes, both of London.*—The chief object of this invention is to construct a machine which will drill both square and round holes. In the accompanying illustrations Fig. 1 is a side elevation, Fig. 2 a part vertical section taken at right angles to Fig. 1, Fig. 3 a sectional plan, and Figs. 4, 5, and 6 details

of a machine constructed according to this invention and for the above purpose. The frame work A is constructed substantially as shown, and has two brackets B, in each of which works two pairs of slides C C¹, the inner ends of which are formed with a notch in them, so that, when brought together, they form a square hole, as shown in Fig. 3. Running between the inner ends of these slides is a sleeve D capable of slight lateral movement, and having formed on its outer periphery six or more pairs of cams E, and rotated by means of gear wheels F and G as shown (Fig. 1). The wheel F is fixed to D by means of a feather working in a slot in the latter, so that the sleeve can move longitudinally in F. Inside D is a rod H carrying the tool H¹ capable of longitudinal movement in D, being raised or lowered by screw I, but rotated by the latter. Around D, in a slot, there is a loose collar J, on which are formed lugs; these project into the piece J¹ attached to the end of a bell-crank lever K, the opposite end of which can be fixed in any desired position by means of a spring catch and notched sector L (Fig. 1). It will thus be seen that either of the six cams on D can be brought between the notched ends of C as desired. The cams E are each of a different cut, the cut depending upon the size of the square hole to be formed, it being necessary to limit the traverse of the cutting tool, formed as shown (Figs. 5 and 6), to suit the size of the hole to be formed, the rule for producing this result being:—Supposing a ½in. square hole is to be cut. The cut of the cam is determined, supposing the square hole formed by the guides C to be 2½in. across, by first drawing an equilateral triangle (Fig. 4), the sides of which correspond to the size of the



hole to be cut. Three arcs of 1in. radius are then described, the point of junction of the sides of the triangle being taken as centres. These arcs are then joined up by other arcs (1½in. radius) described from the centres opposite to the arcs to be drawn, and the form and size of cam required is thus produced. It will thus be seen that each cam represents a different sized hole, and, as shown in Fig. 2, the cams are duplicated for steadiment, as also are the slides C, the second set of slides C¹ being for the purpose of drilling round holes, for which purpose a circular part of D is brought between the square formed between the ends of C¹. Claims: The apparatus substantially as described.—No. 1019. January 20th, 1890. 8*d.*

Dies for Presses.—*S. Fox, New Wortley, Leeds.*—The object of the present invention is to construct dies for producing, by stamping hot metal plates of suitable form, box-like articles having one or more ends or sides bevelled—that is, at an angle other than a right angle to the bottom. For this purpose the inventor uses, in conjunction with the male die of the desired form and usual construction, a female die constructed as follows:—That end or side of the die corresponding to the end or side of the box to be bevelled is made capable of a sliding movement under the influence of suitable pressure such as that of a spring, whilst the external die is caused to enter the internal die, and thus, during the operation of forming the article, pressure is applied to the sliding parts, so that the metal plate is, during the formation of the box-like article, gripped by the male and female dies in such a manner as to prevent buckling or overlapping in the sides or ends of the article being formed. Claims: The construction of a female die used in conjunction with a male die for pressing metal articles substantially as described.—No. 20,000. December 12th, 1889. 6*d.*

Keys for Railway Chairs and Rails.—*R. T. Wilkinson Gargrave, Leeds.*—The key constructed according to this invention is for the purpose of fixing rails in their chairs, and consists essentially of two metal blocks of a wedge shape, the bevelled sides being placed opposite one another. These blocks are held together and can slide on one another by a bolt passing through a suitable opening made lengthwise centrally through each part. On the outer surface of one of these blocks are two lugs, which embrace the side of the chair, so holding the block in position during the operation of screwing the nut on to the bolt so as to slide one block on the other to increase the key's dimensions laterally. A piece of wood may be placed between the key and the chair if necessary. Claims: (1) The formation of keys for holding rails in position in such a manner that their lateral dimensions may be increased or diminished by operating the nut of a bolt substantially as described; (2) the bevelled blocks, the bolt, and piece of wood between the lugs on one of the blocks in combination, the same being formed and arranged for the purpose set forth.—No. 1856. February 4th, 1890. 6*d.*

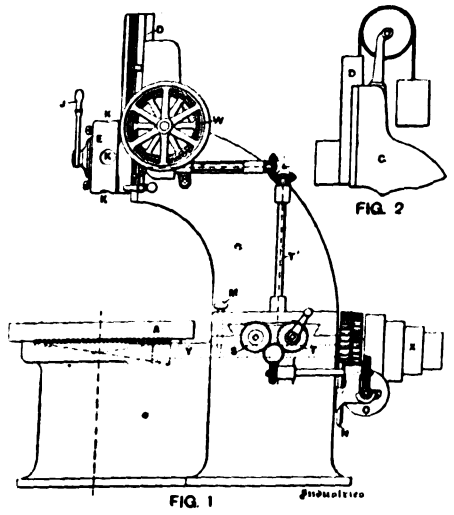
Steam Engine Pistons.—*H. E Bedford & G. Rodger, both of London.*—The chief object of this invention is to prevent unnecessary friction between the piston rings and the cylinder where the former is held against the latter by means of the fluid pressure in the cylinder. Referring to the accompanying illustrations, Fig. 1 is an elevation partly in section, and Fig. 2 a half-plan of a piston fitted and provided with packing rings according to this invention. A is the body of the piston, B the packing rings, C a separate ring acting as a carrier for B, and

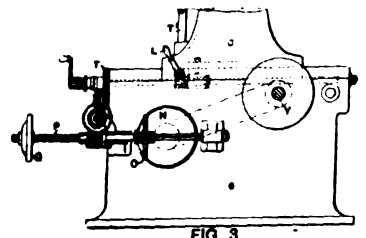
D the junk ring. As shown, two annular chambers E E¹ are formed behind each ring B. Communication between E and the interior of the cylinder is provided by holes F and between E¹ and the cylinder by exterior grooves G. Consequently the pressure on B, tending to force it outwards, is the mean of those in E E¹, and the pressure tending to force it inwards will vary between the pressure at points H and H¹. It so only remains to proportion the relative areas of the two portions of the ring B so that the outward pressure shall be slightly in excess of the inward pressure, so that the piston will be perfectly tight with the least possible friction. The rings B are cut at B¹ and provided with a tongue-piece I, and are so arranged that when the junk-ring is fixed in position they will be free to move easily in the horizontal position with respect to the axis of the piston. Six claims are made, embracing the arrangement of pistons as described, with modification.—No. 1064. January 21st, 1890. 8*d.*

Self-acting Mules and Twiners.—*J. T. Ainsworth, Bolton.*—The invention relates to an improved easing motion in mules and twiners which ensures the underfallers rising smoothly to prevent breakage of the yarns when "backing off." To effect this a spring is employed which is connected at one end to an arm on the underfaller shaft and at the other end to one arm of a small lever fulcrumed on a bracket secured to the front of the carriage. The other arm of this lever is connected by a rod or spring to a hanging arm pivoted on a bracket secured to the back of the carriage. An adjustable stop is secured to the floor in such a position that as the carriage is on the point of completing its outward run the hanging arm comes against the stop and is thus prevented moving forward with the carriage while it makes, say, the last inch of its run, the effect of which is to tighten the spring connected to the arm on the underfaller shaft. As soon as the salmon head lever comes into action to lift the underfaller, the latter rises against the resistance of the spring, whereby a smooth motion of the faller is ensured until the faller has reached its highest position. When the "backing off" has been completed the carriage begins its inward run, and the hanging arm in receding from the stop allows the different parts to resume their original places. By the use of the above arrangement the weight on the salmon head lever may be increased so that better and harder cops may be built. Claims: Two claims are made embracing the arrangement substantially as described.—No. 1664. January 31st, 1890. 8*d.*

Digitized by Google

BORING AND TURNING MACHINES.—*G. Richards, Broadheath, Cheshire.*—In the accompanying illustrations Fig. 1 is a side elevation, Fig. 2 a view of the slide, Fig. 3 a rear view of feed mechanism, and Fig. 4 a plan of the base of a machine constructed according to this invention. A is the table to which the work is attached, B is the main frame of the machine, C is the main bracket in which the slide D moves vertically, E is the turret in which the tools are attached. The main bracket F has a transverse movement on the frame B moved by the screw F. The slide D is rapidly moved vertically by rack G and pinion H, which are connected by gear wheels and shafts to the driving mechanism. The pinion H is also rotated by a suitable hand-wheel. The turret E revolves on the pivot I. The turret is locked in position by the handle J, the tools being inserted in the holes K. When the machine is used for boring, the main bracket C is moved, so that the centre of the turret corresponds with the centre of the table, and is locked to the frame by the handle L. This position is determined by the dowel pin M. The various feed motions of the machine are obtained by means of the friction disc N, which is driven by the main driving shaft, and rotates the friction wheel O. This wheel is fitted to the shaft R by a sliding key, and is moved across the face of the disc N by means of the screw P and the hand-wheel Q, and thus varies the speed of the disc. The shaft R connects with the feed gears S and T attached to the end of the feeding screw F and the shaft U. The latter connects with the vertical shaft T¹, which drives the worm and wheel V and W. This worm-wheel is on the end of the pinion shaft H. It will be seen, therefore, that the rate and the direction of the feed can instantly be changed by rotating the hand-wheel Q and moving





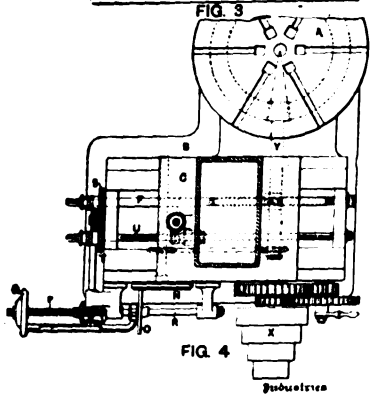


FIG. 1

FIG. 2

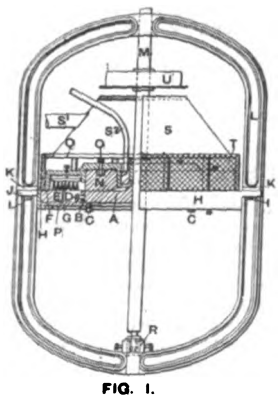

FIG. 3

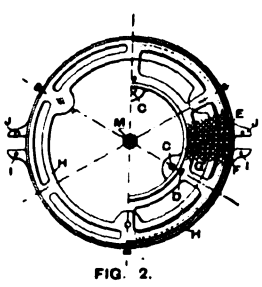

FIG. 4

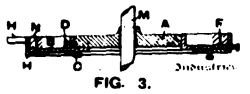

the wheel O on either side of the centre of the friction disc N. The table A running in bearings in the main frame is rotated from X by means of intermediate gearing and shaft and pinion Y as shown. Five claims are made.—No. 19753. December 9th, 1889. 6*d.*

ROVING FRAMES FOR FLAX, &c.—*W. J. Robinson, Belfast, Ireland.*—The inventor prevents "tugging" in the rove caused by irregular or defective action of the differential motion for regulating the speed of the bobbin in relation to the spindles and flyers, as follows:—A flanged socket or sleeve is introduced between the rove bobbin, and the spindle, and between the rove bobbin, and pinion or wharve with which it rotates, and with which the bobbin has only a frictional contact. This sleeve fits loosely on the spindle, and the flange on the former rests upon the top of the bobbin wheel, and is provided with pin-holes which engage with pins in the top of the bobbin wheel. The bobbin fits over and upon the sleeve, and is carried by it and rotates by frictional contact. From the above it will be seen that as the bobbin is carried round by frictional contact it will always tend to run at a uniform speed, without being affected by any slight irregularities in the running of the pinion, which so prevents "tugging." Claims: In a roving frame for flax and similar fibres, the combination with the spindle and bobbin wheel of a flanged sleeve rotating with the bobbin wheel, interposed between the bobbin on the one side and the spindle and bobbin wheel on the other, and with which the bobbin rotates by frictional contact, substantially as described.—No. 1680. January 31st, 1890. 6*d.*

GRAIN CLEANING APPARATUS.—*J. B. Bonnard, Paris, France.*—The inventor here cleans the grain of small stones and such like matter by subjecting it to a slight pressure, which, although not sufficient to crush the grain owing to its elasticity, is sufficient to crush the stones and other foreign matter, and also causes enough friction on the exterior of the grain to clean it. An arrangement of brushes, acting on a riddle, effects the completion of this cleaning by separating and ejecting the heavier foreign matter from the grain, whilst an exhaust fan acting on the whole carries off the lighter particles to the outside. Referring to the illustrations, Fig. 1 is a sectional elevation of an apparatus constructed in accordance with this invention; Fig. 2 is a plan of the machinery of the lower mill, parts being removed on the left-hand half of the figure; Fig. 3 is a transverse section through Fig. 2. The apparatus comprises a lower horizontal mill A of metal, turned and channelled in such a way that the grain drawn down by the upper mill takes a position parallel to the grooving. This mill A is supported by a frame B which has regulating screws C to adjust its position and set screws D for fixing it. The frame carries besides, concentrically to the lower mill A and all round the same, a series of radiating strips or flanges E governed by means of bolts F, and on which the metallic cloth G, constituting the sieve, is stretched. The whole is supported by an annular rim H having regulating screws I, and screws for fixing in position, traversing on the one hand the lugs J cast on the rim, and the plates K on the frame L of the machine. On the fixture above described, a movable device mounted on a rotatable vertical axle M revolves, and comprises an upper mill N with horizontal annular plate fixed and governed by set screw O, and system of brushes P, the position of which can be regulated by means of screws Q. The whole of this

FIG. 1.

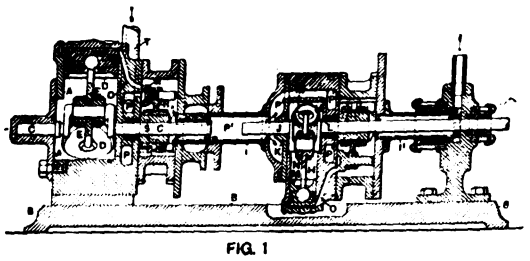

FIG. 2.

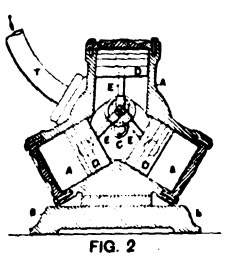

FIG. 3.

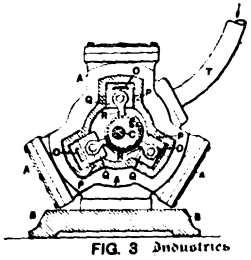

movable apparatus is adjustable by means of the movable foot-piece R. The apparatus is covered with a canopy S in conjunction with which an exhaust fan works by a pipe S¹. A tube S² penetrates into this same canopy which serves for feeding the grain. Around the frame supporting the upper mill and the brushes is placed a fixed sieve T through which the lighter particles of dust detached from the grain escape to the outside. A belt pulley U serves to communicate the motion to all the movable apparatus. The mode of action of the apparatus is as follows:—The grain once introduced by the tube S² falls to the lower mill H, where it is operated upon by the movable mill, which rubs it without crushing it, detaching the impurities which it may have on its surface and pulverising the earth and stones which may be mixed with it. On leaving the mills A and N the grain is brushed by the brushes P, the heavy dust traverses the sieve cloth G in order to fall out of the machine, the grain passes in its turn to any given point, whilst the light dust also passes to the outside through the sieve T under the action of the exhaust fan. Four claims are made.—No. 666. January 14th, 1890. 8*d.*

RAILWAY SLEEPERS AND CHAIRS.—*P. Espinasse, Monclar de Quercy, France.*—The improved sleeper is composed of a double T-shaped steel girder placed flat upon the ground and carrying two chairs of rolled or stamped iron, which are arranged between the upper flanges of the girder at the desired distance apart. These chairs occupy the entire width between the two flanges of the girder; they are made thin at their bases, so that the flanges of the girder can be pressed down upon them and firmly secure them in their places. Snugs formed on the chairs traverse the web of the girder, determine the distance between the chairs, and prevent the sliding of the latter. When a chair has been put in position the flanges of the girder are forced down upon the base of the former by means of a hydraulic press, which at the same time is caused to press the extremities of the said parts upon the web of the girder, so forming shoulders which will hold the chair firmly in position. Claims: (1) A railway sleeper formed of a double T-shaped girder placed sideways upon the ground, and carrying two chairs held between turned-down parts of the flanges of the sleeper as described; (2) in combination with a sleeper as described of chairs whose feet, which are indented at their upper part, occupy the entire width between the flanges of the girder, and which are fixed in their place by forcing down parts of the said flanges as described; (3) the combination of a chair and a sleeper as described; (4) a railway chair fixed as described, and provided at its lower part with a snug, which traverses the said girder and holds the chair in its proper place laterally as set forth.—No. 1498. January 28th, 1890. 8*d.*

HIGH SPEED STEAM ENGINES.—*J. F. Sleat & H. Skelton, both of London.*—The invention relates to an engine in which the motor shaft is driven at a high speed with a comparatively slow piston speed. In the accompanying illustrations Fig. 1 is a longitudinal section, and Figs. 2 and 3 transverse sections through the low-pressure cylinders and valve chest respectively of an engine constructed according to this invention. The low-pressure cylinders A are connected to a base plate B, and through the centre of the casting A the crank shaft C passes. In each cylinder A is a piston D connected, as shown, to C by rods E. The inner end of C is keyed to the casing (supported by sleeves I I¹) of the set of high-pressure cylinders H, as shown, by means of sleeve I. A second crank shaft J passes through the casing of the cylinders H and rotates in the bearings K L. In each cylinder H is a piston M connected to J by rods N. Each cylinder is provided with supply ports O and exhaust port P P¹, and with suitable valves Q to control same, actuated through connecting rods R

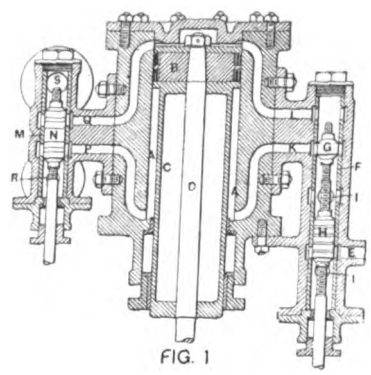

FIG. 1

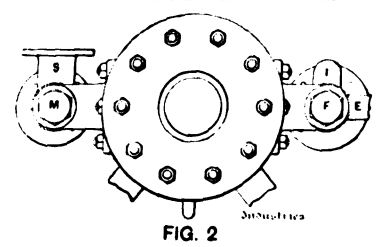

FIG. 2

FIG. 3

connected to eccentrics S mounted on the shafts C and J as shown Steam passes, as shown by the arrows, through the sleeve I¹ to the high-pressure cylinders through passages P¹ and sleeve I to low-pressure cylinders, and escapes by passages P to exhaust pipe T. From the above it will be seen that the shaft J will be driven at a speed equal to that at which the high-pressure cylinders are caused to rotate by the crank shaft C plus the speed at which J is driven by the high-pressure cylinders. In two claims the inventors claim the method of constructing high speed engines in which one cylinder or set of cylinders is fixed whilst the second and third and so on (if more than two sets are used) cylinder or set of cylinders (the pistons of which actuate the main driving shafts) are revolved by the first substantially as described.—No. 1278. January 24th, 1890. 8*d.*

STEAM ENGINES.—*R. Mudgemarchant, London.*—The invention relates to that kind of steam engines in which the high-pressure steam after having done its work in a cylinder on one side of the piston is divided into two parts, one part being used to act on the opposite side of the same piston, and the other part is delivered to another cylinder, so as to actuate the piston therein. Fig. 1 in the accompanying illustrations is a vertical section and Fig. 2 a plan of an engine constructed on the principle of this invention. A is the high-pressure cylinder, B is the piston of this cylinder. The capacity of the cylinder A at the lower end is considerably reduced by fitting a concentric sleeve C around the

FIG. 1

FIG. 2

piston rod D. E is the high-pressure steam supply pipe communicating with valve box F. In this valve box is a valve G and an adjustable check valve H, which is kept in equilibrium by means of a passage I. The valve box has two ports or passages K and L, communicating with A. At the other side of A is another valve box M and valve N, this valve box having two ports or passages P and Q, also communicating with A. The valve box M has also ports or passages R and S communicating respectively with a second cylinder and with a condenser. The high-pressure steam supplied at E and entering the valve box F passes through the port or passage K, which is then in communication with E, to the lower end of the cylinder A, and causes the piston B to make its forward or upward stroke. Then, the steam supply being cut off, one portion of the steam in the lower end of A passes through port K, valve box F, and port L to the other end of the cylinder, so as to cause the piston B to make its return stroke, and the rest of the steam in the lower end of A passes

Digitized by Google

through the port P, valve box M, and port R to the second cylinder so as to operate the piston of same. At any determined point in the return stroke of the piston B the valve N is in such a position that the steam above the piston B exhausts through port Q, valve box M, and port S to a condenser. Claims: (1) The construction and arrangement of valves, boxes, and ports, as described; (2) fluid pressure engines as described and illustrated.—No. 843. January 16th, 1890. 8*d.*

ELECTRICITY.

SHIP SIGNALLING APPARATUS.—*J. Campbell, Glasgow.*—The inventor describes an apparatus for the purpose of transmitting messages electrically from the bridge to the engine-room, the chief object being to minimise the expenditure of electricity. In Figs. 1 and 2 is shown the transmitter, and in Figs. 3 and 4 the receiver. The transmitting handle A can be placed in any of the nine positions defined by the notches B, and

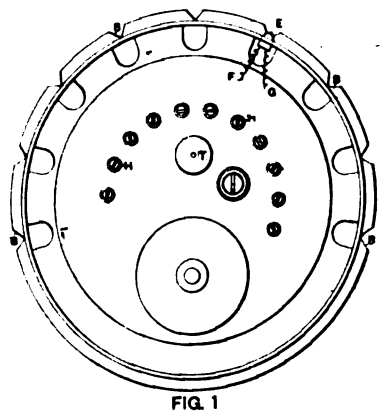

FIG. 1

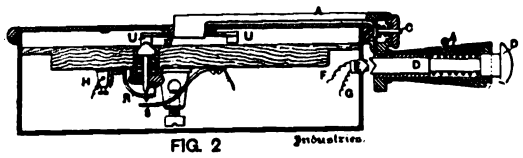

FIG. 2

is held in position there by the spring lock C. By pressing the nob D upon the contact E the circuit in F G is closed. Each wire F is connected with a common source of current, and each wire G is connected to one of the binding screws H, and from thence led to one of a corresponding set of binding screws I in the receiver (Figs. 3 and 4). The wires leading from the screws I pass each round one of nine electromagnets J, and then return to the common source of current. When a current passes round one of the electromagnets J the armature K is attracted, and it pulls with it the pivoted arm L. The lower end of L carries a plate M, which is thus brought over one of the openings N in the indicating dial plate of the receiver. Each plate M bears a particular order or command corresponding with the position of the handle of the transmitter. When the plate M has been brought into position over N it is retained there until the order is countermanded. This is effected by the hooked end

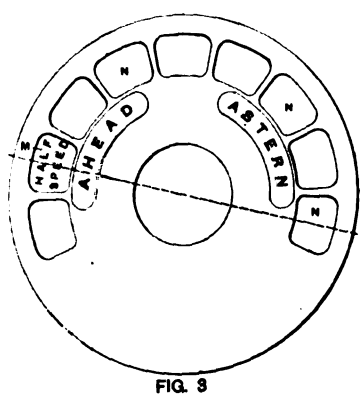

FIG. 3

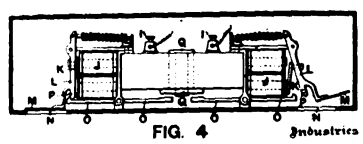

FIG. 4

of the pivoted lever O engaging with the notch P of the arm L. Thus the current of electricity may be switched off and so a saving effected in power. In order to release the notch P and remove the plate M from before the opening N the hinder end of the lever L is made to act as the armature of the electromagnet Q. This magnet is energised by the circuit R S being completed in the transmitter on the piece T being depressed by one of the cams U, which are fixed to a plate V fixed to and turning with the handle A. As there is a cam near every notch B a slight motion of A completes the circuit through Q and so removes M. Four claims are made.—No. 19285. November 30th, 1889. 8*d.*

FIRE ALARM.—*J. Tax & E. Donohoe, both of London.*—The alarm constructed according to this invention consists of a closed metal chamber of any suitable shape, placed horizontally at about the centre of which, so as to divide it in to two compartments, is a concentrically corrugated metallic diaphragm, so fixed that the air in the lower chamber cannot escape. In the upper chamber is placed a horizontal metal bar connected electrically with the diaphragm and carrying two insulating blocks, on one of which is mounted one end of a spring, while the opposite end rests on the other insulating block. Carried by this spring is an adjustable screw, the end of which is in close proximity to the metallic diaphragm. One wire of the circuit, in which the alarm bell and battery are placed, is connected to this spring, and so to the screw on it, and the other wire is connected to the metal bar in the upper chamber and so to the diaphragm. It will thus be seen that as the air in the lower chamber becomes heated by the fire and expands, the diaphragm will be forced upwards, making contact contact with the screw and so completing the circuit. Claims: In an apparatus for indicating rise of temperature electrically an air chamber with a diaphragm, as described.—No. 20506. December 20th, 1889. 8*d.*

SUBTERRANEAN CONDUITS.—*F. Zöpke, Berlin, Germany.*—The conduit forming the subject of this invention consists essentially of a lower part or base and a cover of glazed earthenware, one surface of each of which is corrugated, so that a better joint is formed when the two are placed together. These parts when placed together are in cross section, preferably of an oval form, and have formed between them circular passages. In the lower part of these circular passages segmental grooves are formed into which grooves slide the lower part of an insulator for carrying the conductor. Where secondary circuits are to be connected with the line the upper cover is provided at its upper surface with channels similar to those in the base, but at a suitable angle to the latter, and holes pass from these channels in the cover to those in the base through which the connection is made from the main, a cover of suitable shape being provided to close the upper channels. To facilitate examination of the line manholes are provided at suitable places. They are sunk in the ground to a suitable depth and preferably lined with cast iron. The line is laid with a slight fall towards these manholes, and in the bottom of the latter receivers are placed which communicate with the channels, so that any water condensing in the conduits flows to these receivers, and is from time to time drawn off by pipes in the latter. Claims: (1) The conduits or casings for electric wires substantially as described; (2) in conduits for electric lines the insertion of manholes constructed as described.—No. 19433. December 3rd, 1889. 8*d.*

CHEMISTRY.

MANUFACTURE OF STEEL.—*J. Macintire, Sheffield.*—For the manufacture of steel according to the process constituting this invention a mixture of ingredients as follows is used:—(1) Carbonate of calcium (98½ per cent.) and phosphate of calcium (1½ per cent.), 7oz.; (2) black oxide of manganese, 5oz.; (3) tannic acid, ½oz.; (4) vegetable soot, 2oz., animal charcoal, 2oz.; (5) tar, 2oz., and 2–8oz. hot water. Nos. 1, 2, and 3 are well mixed together, as is No. 4 and also No. 5. Nos. 1, 2, and 3 are then added to No. 5, and when well mixed No. 4 added. The above quantities are suitable for treating 1 cwt. of iron, the iron being treated in the crucible, Bessemer converter, Siemens-Martin open-hearth process or, with any other method. If treated in the Bessemer converter the inventor prefers to introduce the above ingredients in the form of an alloy formed as follows:—40lb. of pig iron is melted to a pasty condition in the ordinary steel crucible, and the above ingredients, mixed as described, but in the following proportions, are added:—Carbonate of calcium and phosphate of calcium, 1¼lb.; black oxide of manganese, 1¼lb.; tannic acid, 1½oz.; soot, ½lb., animal charcoal, ½lb., ¾lb.; tar, 1oz., mixed with sufficient water to make a paste. The proportion of this alloy to be used varies up to 16 per cent. of the iron to be converted. Claims: (1) The improvements in the manufacture of steel or iron, consisting in the manufacture and use of the combination of materials forming a powder or cake substantially as described; (2) the manufacture and use of the above-mentioned combination of materials in the form of an alloy, substantially as described.—No. 213. January 6th, 1890. 6*d.*

EXTRACTION OF GOLD AND SILVER.—*J. Buchanan, Glasgow.*—This invention relates to a process of precipitating gold and silver from the solutions in which they are dissolved in the process of extracting the same by chlorine, bromine, or iodine under pressure or otherwise. This is effected by allowing the liquid so obtained to percolate through iron or steel borings at the ordinary or at an elevated temperature. The gold and silver are thus completely deposited on the iron and may afterwards be removed from the same by riddling and washing or otherwise. In place of iron, copper, brass, zinc, or other metal or alloy capable of precipating gold and silver during the percolation of solutions containing same dissolved by chlorine, bromine, or iodine, may be used, or a combination of one or more of such metals may be used together with charcoal prepared by riddling or otherwise. Six claims are made.—No. 2390. February 14th, 1890. 4*d.*

FIRE EXTINGUISHING COMPOUNDS.—*H. Grimshaw, Clayton, Manchester.*—This invention relates to a new compound to be used for the generation or production of carbon dioxide (carbonic acid), and which is especially adapted for use in gasogenes, fire extinguishers, &c. This compound consists of a mixture of a carbonate or bicarbonate of an alkali or of an alkaline earth, or a mixture of such carbonates or bicarbonates (preferably bicarbonate) of soda with a suitable soluble bisulphate or soluble biphosphate (preferably bisulphate) of soda. The substances constituting the compound are mixed together in the proportions indicated by their molecular weights or thereabouts, allowances being made for impurities and the presence of moisture. Claims: An improved compound for the generation or production of carbon dioxide, consisting of a mixture of a carbonate or bicarbonate of an alkali or of an alkaline earth with a similar bisulphate or biphosphate, substantially as and for the purposes described.—No. 984. January 20th, 1890. 4*d.*

MANUFACTURE OF SODA AND POTASH.—*F. Ellershausen, Hebburn-on-Tyne, Northumberland.*—The inventor effects the above as follows:—A strong solution of black ash is mixed with a sufficient quantity of peroxide of iron to produce a mass having a consistency of a thick paste. This mass is then introduced into a furnace and calcined, whereby it is converted into ferrate of soda. This product is then lixiviated in sufficient warm water to form a strong solution, the soda being converted into hydrate of soda or caustic soda, and the iron precipitated in the form of hydroxide of iron, which can again be used for future operations. This solution of caustic soda is concentrated in the usual manner, the carbonate of soda obtained in this operation being mixed with the black ash during subsequent operations. Caustic potash is manufactured in a similar manner, carbonate of potash being substituted for carbonate of soda. Claims: (1) Improvements in the manufacture of caustic soda or potash from carbonates, consisting in mixing a strong carbonate solution with peroxide of iron, and then calcining and lixiviating the mass as described; (2) in the manufacture of caustic soda or caustic potash the production of ferrate of soda or ferrate of potash as described.—No. 1016. January 20th, 1890. 4*d.*

MISCELLANEOUS.

BOTTLE STOPPERS.—*F. Deimel, Berlin, Germany.*—The object of the invention is to provide a closing device for vessels containing inflammable liquids, which prevents the explosion of such liquids when they are poured from such vessels into fire. For this purpose a cork-stopper saturated with paraffin is fitted into the neck of the bottle. In the centre of this stopper is a tube closed at the top, and which extends some way into the neck of the bottle, and is at the side fitted with a tubular extension forming a spout. The lower end of this tube is closed with wire gauze, and through the gauze passes a second tube extending nearly to the bottom of the vessel and curved at its lower end. The upper end of this inner tube rises higher than the spout, and then curves back to below the end of the outer tube. The outer end of the inner tube has a spherical head fitted with wire gauze. From the above it will be seen that when pouring liquid from the bottle the liquid passes through the gauze at the end of the outer tube and through the latter to the spout, air being admitted only through the gauze and the outer end of the curved inner tube. Claim: A closing device for vessels containing inflammable liquids constructed as described.—No. 19482. December 3rd, 1889. 6*d.*

VALVE FOR METAL LADLES.—*A. H. Holdich, Wigan.*—The inventor constructs the above by fixing to the bottom of the ladle or reservoir a plate of suitable material. Formed in this plate is a hole, in which is fixed a ring of chromic iron ore, lime, magnesia, alumina, or other suitable refractory material, the hole in the centre of which coincides with a hole formed in the ladle. Hinged to the plate, and at a part most distant from the hole carrying the ring of refractory material, is a lever capable of moving in a horizontal plane. Fixed to the upper side of this lever is a block, also of refractory material, which, when the lever is suitably moved, comes opposite the hole in the bottom of the ring on the plate and fits firmly against it and closes it. Claims: The improved valve or stopper for externally controlling the flow of molten metal from the ladle or reservoir employed in steel works, substantially as herein described.—No. 1624. January 30th, 1890. 6*d.*

FIRE BRICKS.—*C. H. Edwards, Liverpool.*—The inventor uses for making fire bricks, and such like semi-fire proof articles, the waste sand from plate glass works, which the inventor has found usually contains about 75 per cent. silica, 20 per cent. glass grinding, 2 per cent. iron, 3 per cent. chlorides of sodium, magnesium, or potassium and emery. This sand is ground with an aluminous material, such as non-ferruginous clay or ground aluminous shale, in the proportion of about $\frac{5}{6}$ths sand to $\frac{1}{6}$th clay. This proportion, however, may be varied down to one part of sand to one part of clay, which depends upon whether the bricks are required to withstand a uniform heat, or continual variations of temperature. After mixing, the whole may be sprinkled with water if necessary, and is then pressed, dryed, &c., in the usual manner. Claims: The manufacture of refractory bricks or fireclay substitute from waste glassmakers' sand, bound with finely comminuted aluminous materials.—No. 2371. February 13th, 1890. 6*d.*

CONSTRUCTING ORDNANCE.—*J. E. Bott, Eyam, Derby.*—This invention consists in providing, in the manufacture of ordnance, a barrel or tube of steel of suitable temper, and after plating the exterior of this barrel with nickel or aluminium, or other slowly oxidisable material, the use of it as a core, around which may be cast a jacket of mild tough steel or aluminium bronze or other suitable metal, so as to gain the longitudinal strength of the tube in conjunction with the resisting power of a suitable cast metal jacket, and by thus casting on the jacket over the whole of the tube the rate of cooling is regular and even, according to the proportional thickness of the cast jacket, so preventing the dangerous strain incidental to the ordinary method of shrinking on the tubes. This method is also applicable to casting manganese steel on to soft metal bushes, which can thus be bored for shafting and the full advantages of manganese steel obtained. Claims: (1) The manufacture of ordnance and other articles by, 1st, preparing a tube, bush, or other part of one kind of metal or alloy; 2nd, coating same by electricity or otherwise with nickel, aluminium, or other slowly oxidisable metal or alloy; 3rd, heating same to a welding heat; and 4th, casting thereon a jacket, exterior or other part, of another kind or quality of metal, substantially as described; (2) the manufacture of ordnance and other articles by, 1st, preparing a tube, bush, or other part of one kind of metal; 2nd, coating same by electricity or otherwise with nickel or other slowly oxidisable metal; 3rd, casting thereon a jacket or other part of another quality of metal substantially as described.—No. 19557. December 5th, 1889. 4*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED PRINTERS' MACHINERY.

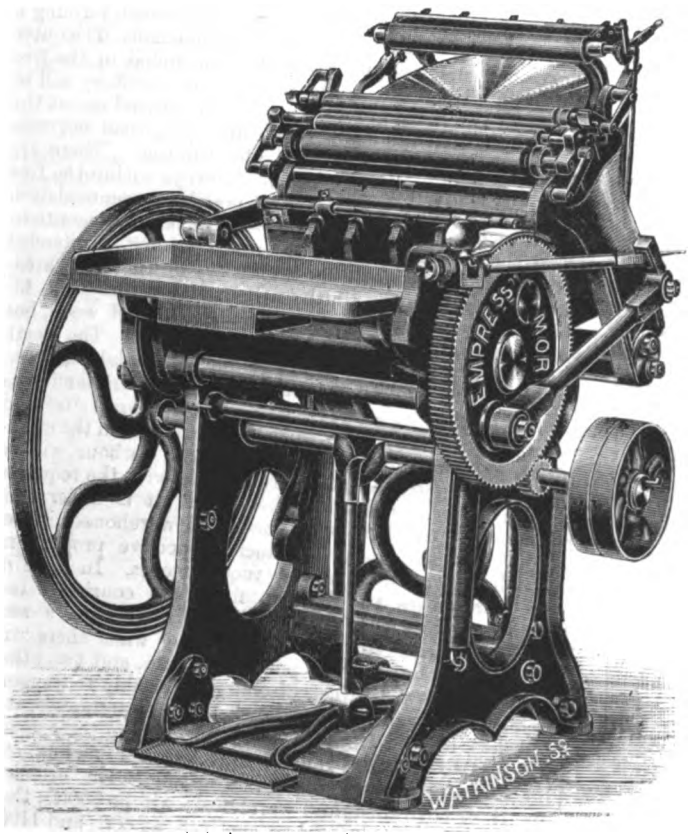

FIG. 1.

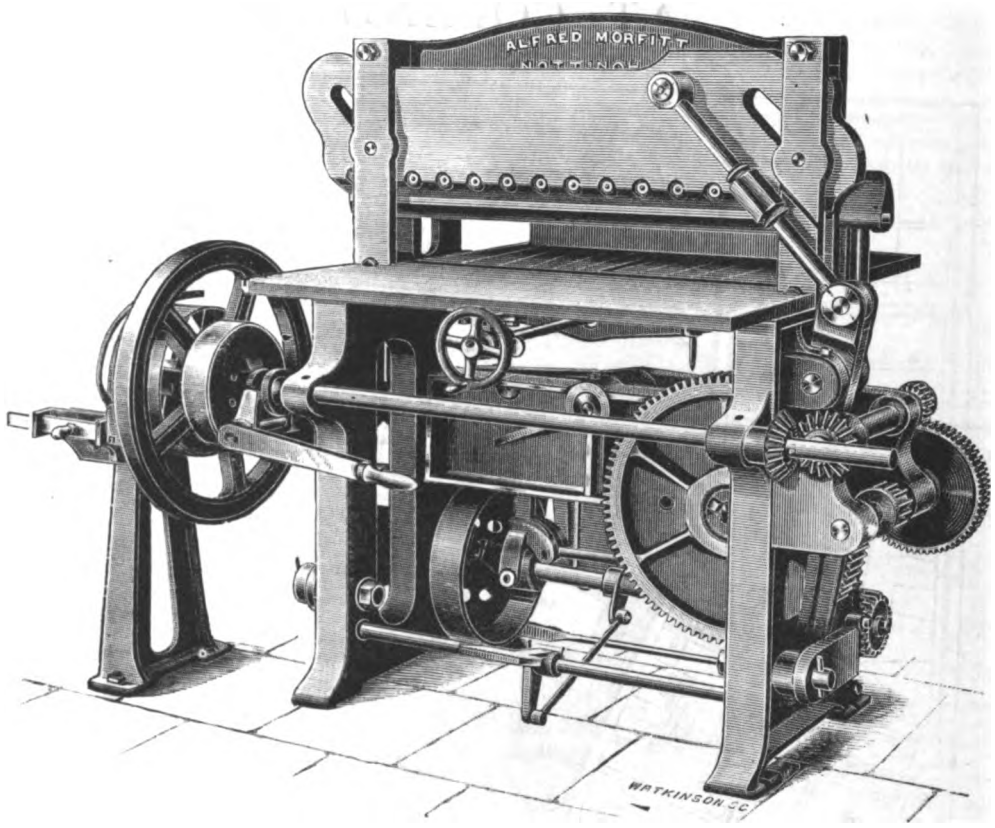

FIG. 2.

IMPROVED PRINTERS' MACHINERY.

WE illustrate above, in Figs. 1 and 2, two new machines –namely, the "Empress" platen printing machine, and the "Empress" self-clamp guillotine cutting machine, both of which are made by Mr. Alfred Morfitt, of Hockley Mill, Nottingham. The first-mentioned machine, shown in Fig. 1, has, in addition to the usual three inking rollers, two "riders," which revolve on and between the former, and at the same time impart a rocking or lateral motion, thereby increasing the printing surface and redistributing the ink, in such a manner that no roller touches two portions of type without receiving fresh ink. A locking apparatus is also provided, consisting of an eccentric shaft which grips the platen frame rigidly against the standards whilst printing. This prevents a "slur," and any wear is taken up automatically by the eccentricity of the shaft. In Fig. 2 is shown a general view of the self-clamp guillotine cutting machine, the novelty of which consists in the manner of holding the material to be cut without the usual weights and springs. This is effected by the employment of a friction clutch, the grip of which is augmented by a powerful lever, so that a variable pressure ranging up to several tons can be brought to bear on the clamping bar with a minimum expenditure of driving power and while the cutting knife is out of action. The machine is of neat appearance, stable, easy and accurate in manipulation, and is fitted for hand or power driving.

THE PROJECTED FREE HARBOUR AT COPENHAGEN.

(*From our Copenhagen Correspondent.*)

IT caused some disappointment that the Danish Parliament, in its recent session, did not arrive at a definite conclusion with regard to this important undertaking, since it was at one time confidently expected that the Government's proposal would have been passed, even if some minor alterations in it were found to be necessary. Although a decision has thus been postponed for a few months, there is every reason to hope that the project will be promptly realised, most people being alive to its great importance. There are at present two plans under consideration, the Government proposal, as it has been modified by the committee of the Landsthing (the Upper House), and another plan, put forward by a private engineer, and supported by several capitalists. We shall first deal with the latter of the two plans.

Mr. J. P. Nielsen is the originator of this plan, which received the first prize at the competition for plans of a free harbour for Copenhagen. Since then he has modified it (see Fig. 1, page 50), so as to meet several minor objections made by the committee appointed to deal with this matter. Mr. Nielsen does not ask for any other favourable conditions than such as generally attach to a concession of this nature. He demands that the State and the Copenhagen harbour authorities shall place at his disposal the areas now in their possession to the north of Copenhagen, where the free harbour is to be placed. He also stipulates for the right of expropriating private owners, if this should be necessary. Mr. Nielsen does not ask for any kind of State guarantee, but, on the contrary, he offers to the State the free use of the projected steam ferry harbour, with all the requisite railway accommodation, &c., such as railway lines, warehouse for railway carriages, and also three steam ferry berths, in addition to which he is willing to lay down a line of railway through the fortification known as "Citadellet," as far the Custom House.

The place selected for the free harbour is almost the same as has been fixed upon in the other projects—viz., that beyond the northern limit of the city. Mr. Nielsen thinks the harbour authorities should carry out the necessary protective arrangements for the vessels in the harbour, such as a breakwater from north-west to south-west on the "Stubbeir," and another from north to south on the "Svanegrunden." It would also be incumbent upon the harbour authorities to carry out all the necessary measurements, &c., outside the harbour. Mr. Nielsen will provide for the works at the "Langelinie" promenade, which should be extended further towards the north. He will also erect the necessary buildings for custom-house offices, &c., as they may be required, and attend to the temporary separation of such parts of the area as in the meantime may be reserved for the local traffic. With regard to the financial aspect of the matter, he proposes that the receipts from the free harbour shall be divided between the State, the harbour authorities (the Copenhagen harbour), and the free harbour, in a proportion which is to be fixed subsequently. The necessary funds for the completion of the undertaking have already been promised by a Copenhagen banking firm. The cost is calculated at about 20,000,000kr., which sum provides for loss of exchange and interest, and for the purchase of some private property wanted for the harbour. Mr. Nielsen states that, as a matter of course, he has also secured the best possible assistance, both with regard to the commercial and the technical sides of the question.

The original plan of Mr. Nielsen's was the most extensive of all those to which prizes were awarded. The area dealt with in the plan was about 175 acres, of which about one-third was water and two-thirds land. It also had the longest expanse of quay—some 13,000 lineal feet —all of concrete, as well as the largest area of quay sheds—about 500,000 square feet. Mr. Nielsen's present plan is still larger, by the addition of a further 12 acres. The area dealt with in the amended plan includes about 35 acres of private property. Of this it will, however, be necessary to purchase only about one-third, as the remaining two-thirds can remain in the possession of the present owners, most of whom will be only too pleased to have their land included in the free harbour territory. The proportions of land and water are about the same as in the original plan, rather more than two-thirds being land, and a trifle less than one-third water. The total length of quay is now increased to 16,000 lineal feet, of which about 3,000ft. are in the ferry harbour. The various basins in the harbour are as follow:—A Mediterranean basin, an American basin, the steam ferry harbour, an English basin, a Baltic basin, and a petroleum basin. The largest of these are to have 25ft. of water, and lengths of 1,500ft., 1,900ft., and 1,750ft. The length of the projected railways is about 18 miles. The steam ferry harbour, with all its requisites, will entail a cost of some 2,000,000kr.; sheds, warehouses, offices, &c., will entail an expenditure of about 7,000,000kr.; and cranes, engines, &c., about 1,500,000kr.

It is calculated that the harbour could be completed within three years from the date of beginning. During that time the harbour excavations, the building of the quays, the filling up and regulating of the site, the construction of roads, railways, steam ferry harbour, fencing, offices, requisite sheds, the lighting appliances, &c., should all be completed. This can, however, only be done by building a dam and pumping out the water so as to lay dry the building sites, which will cost about 400,000kr. A certain number of buildings must be erected in the first instance, and the erection of other buildings is afterwards to be gradually proceeded with.

As the Danish Government did not see its way to accept and endorse any of the various plans received, a fresh plan was directed to be made out by the Copenhagen harbour authorities, which was submitted to Parliament in its recent session. This plan was, on the whole, accepted by the Upper House, but the Second Chamber wished the consideration of the plan to be referred to a joint committee. According to the Government plan, which is shown in Fig. 2, page 51, the free harbour is to be situated to the west of the present Copenhagen inner roads, immediately to the north of the Frederikshavn fortifications. It is to be constructed by and on account of the Copenhagen harbour authorities, and it is to form a part of the Copenhagen harbour,

THE PROJECTED FREE HARBOUR AT COPENHAGEN.

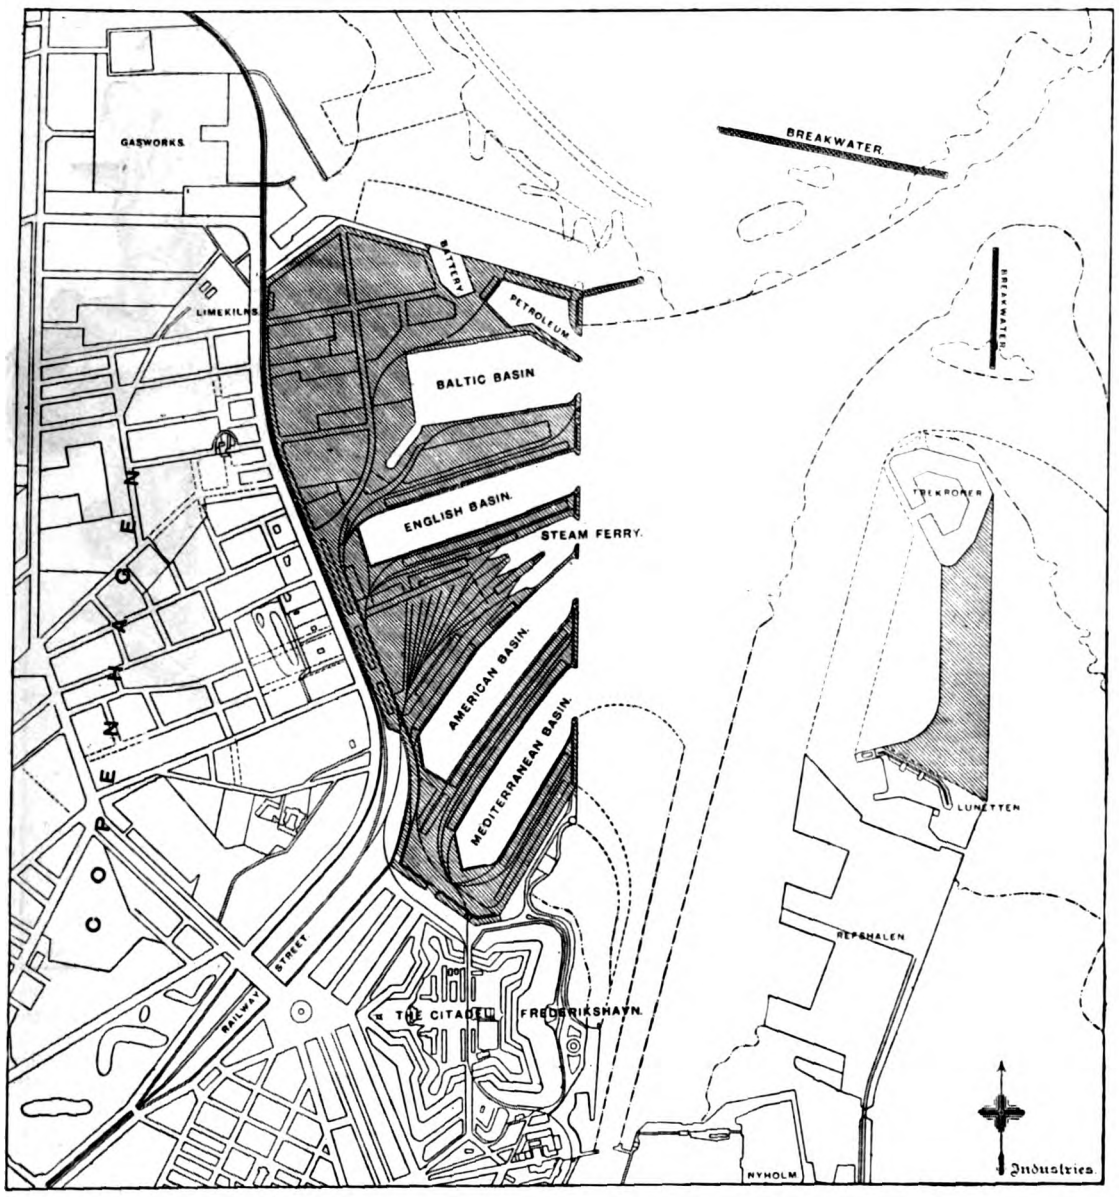

FIG. 1.—SKETCH PLAN OF MR. J. P. NIELSEN'S SCHEME.

comprising, however, the necessary land areas for industrial and commercial undertakings. The Minister of the Interior is to be authorised to build a railway station at the free harbour for goods traffic, and to lay down connections with this railway station to the south to the Custom House, and to the west to a point on the North Zeeland Railway, such stations and junctions to be State railways. The third body, which is to have a share in the working of the free harbour, is a private limited company, which should have been formed before July 1st last year if the Act had been passed during last session. This company will undertake the erection of the necessary commercial warehouses, sheds, cranes, and landing and shunting rails, the minimum capital required being 3,800,000kr. As an equivalent for this outlay the company is to have the working of this part of the free harbour for a period of sixty years. In the agreement between the harbour authorities and the company, it shall be specified what percentage of the annual net profits is to be paid to the company's shareholders in advance, while the rest shall be divided between the company and the harbour authorities in a proportion to be previously agreed upon. The agreement shall also contain the necessary clause concerning the harbour authorities' possible right to take over the company's buildings, &c., at the expiration of the latter's lease. The Government guarantees the interest and amortisation of the bonds which the harbour authorities may issue for the purpose of raising the necessary capital, but the amount is limited to 8,500,000kr. The cost of railway connections, &c., has been calculated at 1,055,000kr., exclusive of the cost of expropriating the land. The requisite area for the steam ferry harbour will have to be reserved, so that the State can take it over either at a valuation or at its actual cost.

The free harbour, as now proposed by the Government, would be protected by breakwaters between the existing fortifications of "Lynetten" and "Trekroner," as also by similar appliances to the north of the latter fortification, on both sides of the "Kronelöb." It is proposed to divide it into two separate harbours (in Nielsen's plan there are five separate harbours), between which the contemplated steam ferry harbour would be located. The south harbour will consist of a reservoir about 2,000ft. long and about 650ft. broad at bottom. Its direction will be very nearly due north and south, and it will occupy the space between the steam ferry harbour and the Frederikshavn fortifications. The entrance will be at the north-east corner, and will be used in common for the south harbour and the contemplated steam ferry harbour. Towards the east the harbour will be protected by a pier of about 250ft. in breadth. The present popular "Langelinie" promenade will be preserved, and a small harbour provided for yachts and pleasure boats. The north harbour will comprise the already existing "Kalkbränderi" harbour (with certain restrictions as to the use of its northern pier) and a 450ft. broad reservoir to the south of this. All the reservoirs mentioned are to have a depth of 24ft., but the various enclosures are to be so constructed that the depth of water in the reservoirs may afterwards be gradually increased to 28ft. The water area of the free harbour will thus comprise about 2,240,000 square feet, with about 8,800 lineal feet of quay. The south harbour is to have 1,400,000 square feet of water area and 5,000 lineal feet of quay, and the north harbour is to have 840,000 square feet of water area with 3,800ft. of quay. The land area, according to the project, amounts to 3,752,000 square feet, of which rather more than 600,000 square feet will be reserved for the steam ferry harbour. The west boundary for the free harbour will be defined by the railway forming the junction between the free harbour and the State railway system, along which runs a road, 60ft. broad, forming a continuation of the "Langelinie" promenade. The outer portion of the east pier will not be included in the free harbour. The access to the free harbour territory will be through two main gates, one at the north and one at the south end, and there will be a connecting road between the two along the inside of the frontier. There are ample provisions for roads and railways within the free harbour territory, with the best possible accommodation for direct loading and discharge. The proposal mentions that the deepening out of the reservoirs, &c., is intended to be effected through the laying dry of the water areas in question. In the south harbour all the quays are, for various reasons, intended to be made, not of wood, but of stone, which will rest on high piling. The north harbour is principally intended for industrial purposes, and for the landing of rougher goods. The land area here will, thus for the most part, remain as open sites, and only the necessary quay lines and roads will, in the meantime, be here carried out. The south harbour will be adapted for regular commercial uses, with the requisite railway lines, warehouses, sheds, &c. It is under contemplation to place both sheds and warehouses immediately at the quays, in such respective proportions as will depend upon actual requirements. In some of the warehouses the bottom floor will consist of one large compartment, which will thus serve as a sort of shed if required. Along the quay walls there will be a railway line for the portable cranes, and two other railway lines for direct discharge from ship to waggon. Behind these rails will be the sheds and warehouses, at a distance of 35ft. from the quay, and behind these again will be two or three railway lines, one for loading, one for forwarding, and one for shunting. The ordinary length of both sheds and warehouses will be 350ft.; their breadths have been fixed respectively at 60ft. and 110ft. The shed on the east pier will, however, have larger dimensions, and be 165ft. in breadth. It has been proposed to have an interval of 100ft. between the different buildings, partly in order to reduce risk of fire, and partly so as to have ample room for traffic. There will, in the first instance, be built four sheds, of which one is to be on the east pier. The ends will be of brick, and both the sides of corrugated iron, which are not to be fixed, but are to be movable like sliding doors. The floor of the sheds is to be on a level with the bottom of the railway trucks. The roof will be constructed of wrought iron and wood, and it will be supported by a row of iron pillars in the centre. The height inside will be 15ft. At the outset two warehouses are to be built on the east pier; they will contain cellars, ground floors, two lofts, and a top loft. Here, too, the ground floor will be on a level with the bottom of the railway trucks, and the harbour cranes will be able to convey the goods straight to the top loft. The warehouses will be divided into several fireproof sections, each with its fireproof staircases and elevators between the various floors. Both warehouses and sheds will be fitted with outside platforms 6ft. broad for the removal of goods from one section to another. Altogether the means of communication, both inside the free harbour territory and between this and the outside, have been very carefully considered and liberally provided for. There will, of course, be the requisite buildings for the harbour and other offices, including the custom house offices, engine and boiler house, fire and police station, offices for merchants, &c. There will be no offices allowed in the warehouses themselves. The majority of these buildings will be placed at the interior quay of the south harbour. The free harbour will be amply fitted with hydraulic cranes and other lifting appliances, and both cranes (stationary as well as travelling), elevators, and winches will be constructed for a capacity of a ton and a half.

In order to carry out the foregoing plan the following areas will be required, in addition to the area which will be obtained through filling up:—

1,656,800	square	feet,	belonging	to	the Copenhagen Harbour Authorities.
97,200	,,	,,	,,	,,	Danish State.
3,600	,,	,,	,,	,,	Corporation of Copenhagen.
467,600	,,	,,	,,	,,	Private owners.
2,225,200	square feet.				

The Landsthing has modified the foregoing plan so far as to particularise the preference dividends to the shareholders in the Warehouse Company at 4 per cent. per annum; of the remainder a quarter goes to the company and three-quarters to the harbour authorities. The limit of State expenditure for railway junctions, &c., has been fixed at 585,000kr., exclusive of expropriation expenses.

INCREASED BOILER PRESSURE AND PISTON SPEED FOR MARINE ENGINES.*

THE object of this paper is to raise a few questions as to the advisability of increasing (1) the working pressure and (2) the piston speed of marine engines, and to consider what type of engine and boiler would best suit these new conditions. The superiority of the three-crank triple-expansion engine over the old two-crank compound is generally attributed to three causes:—First, to increased working pressure giving a greater total temperature range, and allowing of a greater ratio of expansion; secondly, to decrease of temperature range in each cylinder, thus causing less less from cylinder condensation; and, thirdly, to increased piston speed.

To compare the economy of steam of 165lb. absolute pressure with steam of 115lb. absolute pressure, let it be assumed that we have 1lb. of dry saturated steam at 115lb. absolute pressure. A certain quantity of coal has been expended to produce this lb. of steam, and the first question which arises is—How much coal will be expended to produce 1lb. of steam at 165lb. absolute pressure? The efficiency of the heating surface should be rather less in the case of the higher pressure, as the temperature of the water will be higher. Assuming, however, that the efficiency is not appreciably decreased for the extra rise of temperature (72° Fahr.), then for the same amount of coal expended we have—

$$1 \times \frac{\text{Total heat of 1lb. steam at 115lb. pressure}}{\text{Total heat of 1lb. steam at 165lb. pressure}} = \cdot 99305\text{lb. steam}$$

at 165lb. absolute pressure, to compare with 1lb. of steam at 115lb. absolute pressure.

Next, assume that the steam of 115lb. pressure is expanded adiabatically to 8lb. absolute, and that the steam of 165lb. pressure is expanded to 6lb. absolute, the back pressure in both cases being 4lb. (using a formula given by Rankine for the amount of liquefaction due to expansive working), we have for the proportion of liquefied water at the end of expansion the expression—

$$1 - \frac{T_2}{H_2}\left(\text{J hyp. log. } \frac{T_1}{T} + \frac{H_1}{T_1}\right),$$

where T_1 = absolute initial temperature;
T_2 = absolute temperature at end of expansion;
H_1 = latent heat per lb. of initial steam;
H_2 = latent heat per lb. of steam at end of expansion.

Thus, for steam of 115lb. absolute pressure, and terminal pressure 8lb. absolute—

$T_1 = 799{\cdot}01°$ Fahr.,
$T_2 = 644{\cdot}11°$ Fahr.,
$H_1 = 675{,}864$ ft. lbs.,
$H_2 = 761{,}381$ ft. lbs.,

and the proportion of steam liquefied = 14·34 per cent.; so that, at the beginning of expansion, there is 1lb. of steam at 115lb. absolute pressure, and at the end of expansion ·8563lb. steam at 8lb. absolute pressure and ·1437lb. water. For convenience, let it be assumed that this proportion does not vary during the exhaust period. Then, heat received = total heat of 1lb. steam at 115lb. absolute pressure = 1,216·974 thermal units. Heat rejected = total heat of ·8563lb. steam at 4lb. absolute pressure = 998·843 thermal units + heat of ·1437lb. water at same temperature = 22·043 thermal units. Total heat rejected = 998·843 + 22·043 = 1,015·886 thermal units,

1,216·2,741 − 1,015·886 = 201·088 thermal units utilised.

For steam of 165lb. absolute pressure, and terminal pressure 6lb. absolute--

$T_1 = 826{\cdot}94°$ Fahr.,
$T_2 = 631{\cdot}32°$ Fahr.,
$H_1 = 660110$ ft. lbs.,
$H_2 = 768{,}333$ ft. lbs.,

and the proportion of steam liquefied at the end of expansion = 17·29 per cent., so that, at the beginning of expansion, we have ·99305lb. steam at 165lb. absolute pressure, and at the end of the expansion ·82136lb. steam and ·17169lb. water at 6lb. absolute pressure. Then, heat received = total heat of ·99305lb. steam at 165lb. absolute pressure = 1,216·974 thermal units. Heat rejected = total heat of ·82136lb. steam at 4lb. absolute pressure = 953·29 thermal units + heat of ·17169lb. water at same temperature = 26·339 thermal units. Total heat rejected = 953·29 + 26·339 = 979·629 thermal units.

1216·974 − 979·629 = 237·345 thermal units utilised.
Heat utilised with steam of 115lb. absolute pressure = 201·088 thermal units.
Heat utilised with steam of 165lb. absolute pressure = 237·345 thermal units.

$$\frac{237{\cdot}345 - 201{\cdot}088}{201{\cdot}088} \times 100 = 18 \text{ per cent. economy of 165 steam over 115lb. steam.}$$

Passing on now to the second alleged cause of the economy of the triple-expansion engine, the general effect of cylinder condensation is to cause a lowering of temperature at the beginning of the stroke and a raising of temperature at the end of the stroke, as indicated by the heat diagram, Fig. 1, on page 52. A B C D E represents the heat diagram of an engine in which there is no initial condensation, B C being an adiabatic curve produced down to the zero of temperature. The heat diagram of an engine in which initial condensation takes place is indicated by F G H D E, A B G F representing the amount of heat stored up in the walls of the cylinder at the point of cut-off. By the principle of work the area under the curve A B C is equal to the area under the curve F G H, so that if the process were carried down to the zero of temperature there would be no loss from cylinder condensation; but as in practice the process must be stopped at a point J, say, the difference between the areas A B G F and G J K will represent the amount of loss due to condensation. Or suppose 2lb. of steam are admitted to a cylinder at 100lb. pressure, and that 1lb. is condensed on the cylinder surfaces, then let the steam be expanded down to 50lb. pressure, assuming that all the condensed steam is by that time re-evaporated. Divide the period of expansion into any number of stages. At the beginning of expansion there is 1lb. of steam at 100lb. pressure, and by expanding it down to 50lb., a certain amount of energy can be extracted to do external work. At the end of the first stage a certain amount of the condensed steam will have been evaporated by the heat contained in the cylinder walls, and will be available for doing work. It is, however, at a lower temperature than the initial steam, and therefore has less potential energy. By dividing the period of expansion into a sufficient number of stages, and adding up the available energy of each portion of steam as it gets re-evaporated, and comparing the total thus obtained with the available energy of 2lb. of steam for the total temperature, an idea of the loss due to condensation between the assumed limits may be obtained. Condensation in the cylinder may be prevented by means of a steam jacket, but no economy can be effected thereby. Suppose a certain quantity of steam at 100lb. pressure, containing 200 thermal units, be admitted to an unjacketed cylinder, and assume that the walls of the cylinder absorb 100 thermal units, a certain amount of energy will be extracted from the remaining 100 thermal units, and also a certain portion of the heat stored up in the cylinder walls, will, as expansion proceeds, become available for doing work.

Next, suppose the cylinder to be jacketed with steam of 100lb. pressure. If no steam be condensed on entering the cylinder, it follows that the walls must have absorbed 100 thermal units from the steam in the jacket. In the one case 200 thermal units have been put into the cylinder and 100 thermal units into the jacket, up to the point of cut-off; and in the other case (to secure equal conditions—viz., 200 thermal units at initial temperature at point of cut-off), 300 thermal units are put into the cylinder direct, the result being the same in both cases. Thus no economy can result from the use of a jacket, but it may be very convenient in cases of great ratios of expansion to prevent flooding of the cylinder. It must not be forgotten that the jacket is also transmitting heat to the steam and water in the cylinder during the period of expansion. If the steam in the cylinder has no water mixed with it at the beginning of the expansion the jacket will prevent liquefaction due to expansion, or it may possibly superheat the steam. This transmission of heat from a higher to a lower temperature involves a loss. Suppose, for example, that 100 thermal units were transmitted to the steam in the cylinder during the period of expansion, by jacket steam. The amount of loss in this case is measured by the difference in the efficiency of 100 thermal units at 100lb. pressure and 100 thermal units at some temperature *lower* than this. This argument also applies to all cases where steam of a higher pressure gives up heat to steam of a lower pressure, as happens between the steam and exhaust side of a slide valve, and also where exhaust steam is in contact with the cylinder walls.

The next question which arises is, What is the action of condensation as effected by division of temperature range by passing the steam successively through two or more cylinders? For the means of comparison let us take as examples a simple engine and a compound, the low-pressure cylinder of the compound being of the same capacity as the single cylinder of the simple engine. For convenience let it be assumed that in the case of the compound engine the same amount of steam is condensed in each cylinder. Suppose, for example, that 4lb. of steam are admitted to the high-pressure cylinder, of which 1lb. is condensed up to the point of cut-off. Assume that this pound of water will be re-evaporated by the end of the stroke. The steam is then admitted to the low-pressure cylinder, and 1lb. of it condensed up to the point of cut-off, the water, as before, being re-evaporated by the end of the stroke. This process can be represented by a diagram (see Fig. 2, page 52). Let horizontal ordinates represent weights of steam, and vertical ordinates temperatures. A C will represent the 3lb. of steam present at point of cut-off in the high-pressure cylinder. For the sake of simplicity let it be assumed that the re-evaporation of the condensed steam follows the line C F, so that in the high-pressure cylinder the amount of loss may be represented by the triangle C B F, and similarly in the low-pressure cylinder by the triangle F F J, so that the total loss may be indicated by the rectangle E F J H. Now, what will happen in the case of the simple engine? The surface for condensation will be, roughly, about one-fourth less than before, owing to the earlier cut-off, but it is raised through twice the temperature. Under these conditions it is probable that more than 1lb. of steam will be condensed—say, for example, an amount equal to K B. Then the loss will be represented by the triangle K J B, and the double cylinder will be more economical by the value of the triangle K J C. Of course, there are no grounds for assuming that the re-evaporation takes place as indicated here, but it will serve to show why an economy should result from divided temperature range.

As regards the third cause of the economy of the triple-expansion engine—viz., increased piston speed—the advantage of this is evident. Take the case of two identical engines, one, however, running at twice the number of revolutions of the other. The amount of steam condensed will be the same in both engines, but the proportion of steam condensed to steam passing through the engine (which measures the loss) will be very much less in the fast running engine. Thus an increase of revolutions should always tends towards economy of steam. The increase of piston speed in the case of the triple-expansion engine compared with the compound has not, however, been very great. As pointed out before, the economy of steam of 150lb. pressure over steam of 100lb. pressure is 18 per cent., assuming the boiler efficiency to be the same in both cases.

The generally admitted economy of the triple-expansion engine is 20 per cent., from which it would appear that the economy has been mainly due to the increase of the working pressure and increased expansions, and that the effect of the decreased tem-

INCREASED BOILER PRESSURE AND PISTON SPEED FOR MARINE ENGINES.

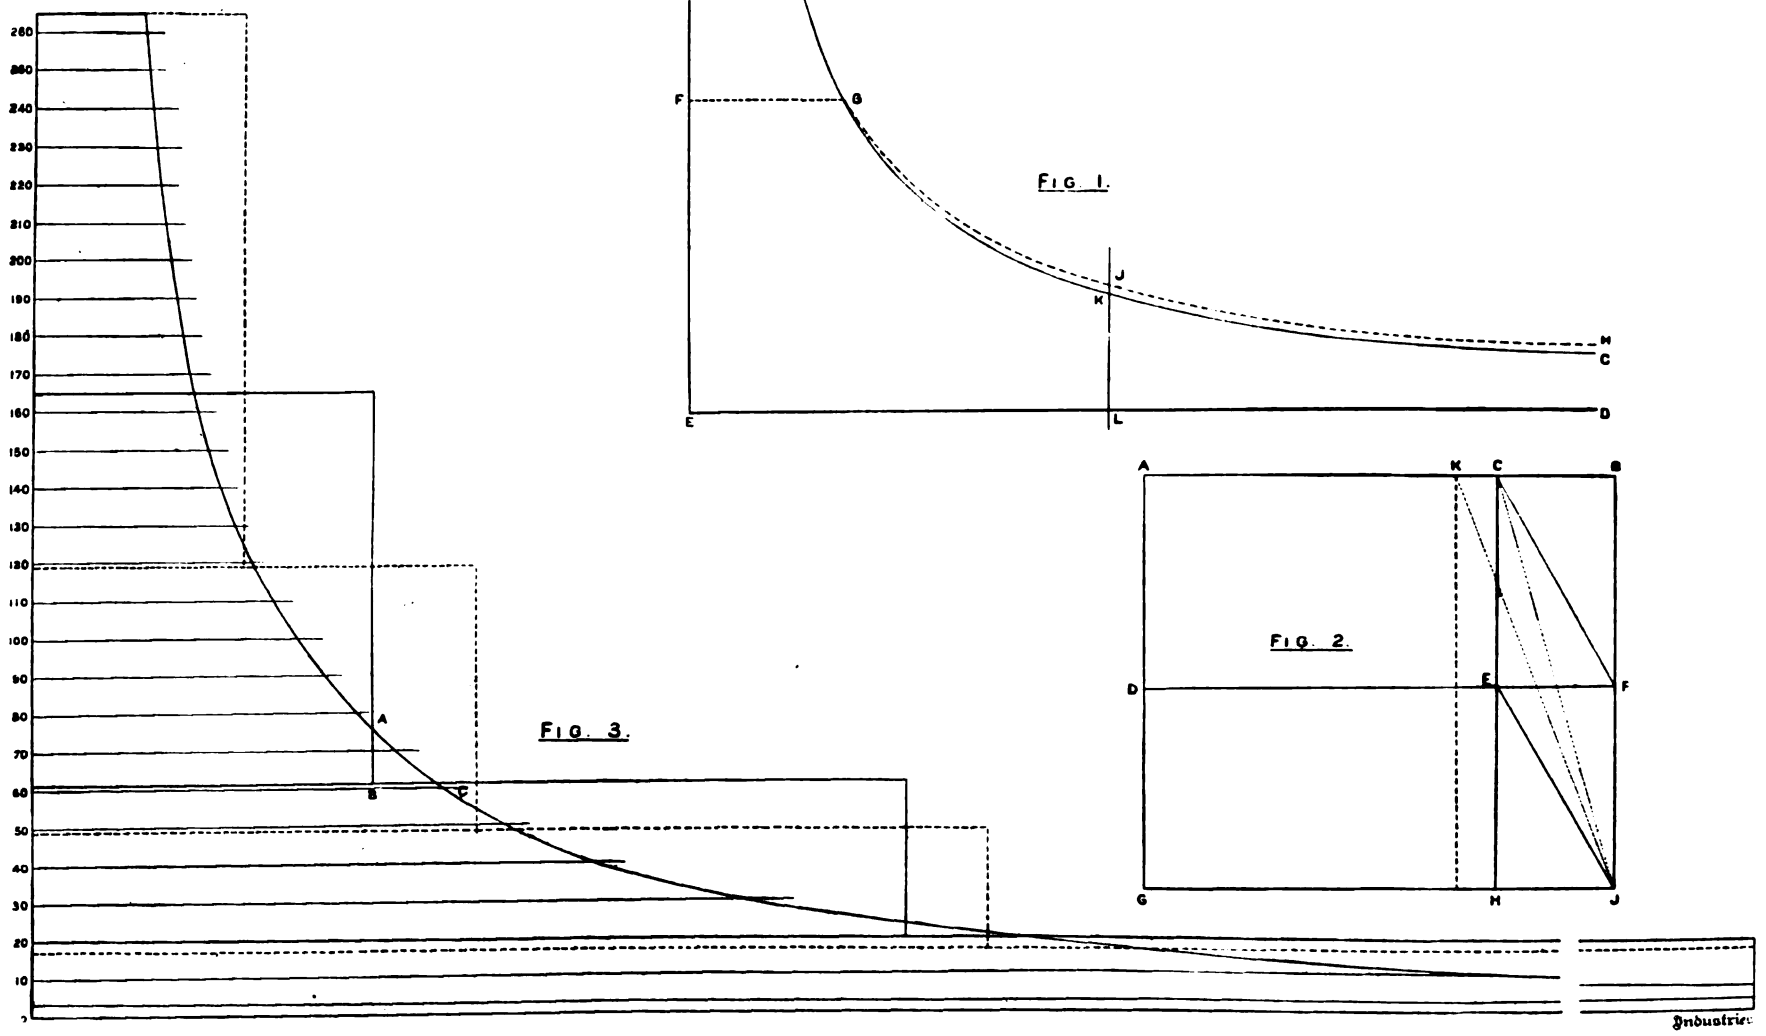

FIG. 3.

FIG. 1.

FIG. 2.

perature range in the cylinders and increased piston speed has in this case been inappreciable. Using the formula as given before for calculating the efficiency of steam of 220lb. absolute pressure expanded to 5lb. absolute, we have—

$T_1 = 851{\cdot}04°$ Fahr.,
$T_2 = 623{\cdot}53°$ Fahr.,
$H_1 = 646{,}423$ft. lbs.,
$H_2 = 772{,}561$ft. lbs.,

and the proportion of steam liquefied at the end of the expansion = 19·32 per cent. The weight of initial steam—

$$= 1 \times \frac{\text{total heat of steam at 115lb. absolute pressure}}{\text{total heat of steam at 220lb. absolute pressure}} = {\cdot}98713\text{lb.};$$

so that, at the beginning of expansion, we have ·98713lb. steam at 220lb. absolute pressure, and at the end of expansion ·79642 steam at 5lb. absolute pressure and ·19071lb. water. Heat received = total heat of ·98713lb. steam at 220lb. absolute pressure = 1,216·974 thermal units. Heat rejected = total heat of ·79642lb. steam at 4lb. absolute = 924·344 thermal units + heat of ·19071lb. water at same temperature = 29·254 thermal units. 924·344 + 29·254 = 953·598 thermal units rejected.

1,216·974 − 953·598 = 263·376 thermal units utilised.

Thermal units utilised by steam of 165lb. absolute pressure = 237·345.

$$\frac{263{\cdot}376 - 237{\cdot}345}{237{\cdot}345} \times 100 = 10 \text{ per cent.}$$

economy of steam of 220lb. absolute over steam of 165lb. absolute pressure.

For steam of 265lb. absolute pressure expanded to 5lb. absolute—

$T_1 = 867{\cdot}04°$ Fahr.,
$T_2 = 823{\cdot}53°$ Fahr.,
$H_1 = 637{,}267$ ft. lbs.,
$H_2 = 772{,}561$ ft. lbs.,

The proportion of steam liquefied at the end of expansion = 20·17 per cent. Weight of initial steam—

$$= 1 \times \frac{\text{total heat of 1lb. steam at 115lb. absolute pressure}}{\text{total heat of 1lb. steam at 265lb. absolute pressure}} = {\cdot}98323\text{lb.}$$

steam at 265lb.; so that, at the beginning of expansion, we have ·98323lb. steam at 265lb. absolute pressure, and at the end ·78492lb. steam at 5lb., and ·19831lb. water. Heat received = total heat of ·98323lb. steam at 265lb. absolute pressure = 1,216·974 thermal units. Heat rejected = total heat of ·78492lb. steam at 4lb. = 910·997 thermal units + heat of ·19831lb. of water at same temperature = 30·419 thermal units, 910·997 + 30·419 = 941·417 thermal units rejected.

1216·974 − 941·417 = 275·557 thermal units utilised.

Thermal units utilised by steam of 165lb. pressure = 237·345.

$$\frac{275{\cdot}557 - 237{\cdot}345}{237{\cdot}345} \times 100 = 16 \text{ per cent.}$$

economy of steam of 265lb. absolute pressure over steam of 165lb. absolute pressure.

If, taking into consideration the gain of 16 per cent. in steam economy and the admitted economy of high piston speed, it is deemed advisable to increase the boiler pressure to 250lb. per square inch, and also to increase the piston speed, the next question to be decided is—What type of engine will best suit these new conditions? There are several types of engine which could be adopted, viz., two-crank four-cylinder tandem, two-crank three-cylinder tandem, three-crank three-cylinder, and four-crank four-cylinder. The two first are not at all suitable for high speeds, so that the choice lies between the two last. In the first place, the four-cylinder type has an advantage over the three-cylinder type in the matter of steam distribution, as the cut-off must be much earlier in the three-cylinder engine. This early cut-off, besides making the engines unhandy, only allows of a small valve opening, thus necessitating a large travel to get the requisite steam opening. The travel of the valves is limited by the length of the cylinders, the limit being often reached with engines of the present type.

As regards the maximum piston speed at which the two types could be run, the three-cylinder engine would have a greater initial pressure to counterbalance the inertia of the moving parts; but, on the other hand, the four-cylinder engine having less initial pressure, would have less weight of moving parts. As, however, the weight of the moving parts is proportional to the initial load, the maximum piston speed will be the same for both types. Another advantage of the four-crank type is, that only two sets of valve gear are required; so that, on the whole, it would appear that the four-crank four-cylinder type of engine will be the most suitable for the new conditions.

We now pass on to the design of the cylinder ratios, &c., for the new pressure, after which the revolutions may be fixed. The usual method of designing cylinder ratios, points of cut-off, &c., is to arrange that the indicated horse-power developed in each cylinder should be the same. The indicated horse-power of each cylinder being the same, the initial loads may or may not be equal (in most cases they are not equal), and since the piston rods and connecting rods are always in duplicate, it follows that they must be designed to transmit the highest of the initial loads. The writer ventures to suggest that cylinder ratios, &c., should be designed so as to obtain equal initial loads in each cylinder. By this method the greatest economy is obtained in the weight of the reciprocating parts, a very important point in high-speed engines. The method used in the present instance has been to combine actual diagrams from a triple-expansion engine of 160lb. boiler pressure (see Fig. 3, above).

Since the diagram is for comparative purposes only, the cards have been set off without taking account of clearance and compression, and the steam curve continued up to 265lb. pressure, has, for the sake of simplicity, been plotted as a constant weight curve. The back pressure has been taken at 3½lb. on the low-pressure piston. The ratios for the triple have been so arranged as to give equal initial loads with a minimum of "drop" between the cylinders. It will be seen from the diagram that there is a considerable "drop" between the first and second cylinders. This is owing to the necessity of keeping the first cylinder small, so that the cut-off need not be too early. The quadruple has been arranged on the same method. It will be noticed that the drop between the cylinders is very small. The loss from drop is represented very nearly by the area of the triangular piece A B C. A certain quantity of heat is, however, regained, as the steam on expanding into the receiver, without doing work, will, if dry, become superheated, or if it contains suspended water, a portion of it will be evaporated, and become available for doing work in the next cylinder, from which it will be seen that, if a drop cannot be avoided, it will be best to arrange it at the higher pressure, so that the greatest amount of heat may be regained, as the farther the expansion is carried the greater the amount of heat regained. It may be argued that with large "drops" smaller cylinders may be used; consequently the engines would weigh and cost less. The most economical amount of drop will be reached when the percentage of loss caused by any further "drop" is greater than the percentage of weight saved by using a smaller cylinder. These same considerations apply to the most economical number of expansions of the steam. By increasing the number of expansions, more work is obtained from the steam; but at the same time the engines will be larger, and the limit to the number of expansions will be reached when the percentage of gain due to any further increase of expansion is less than the percentage of weight added to the engines.

Coming back to the diagram, it will be seen that the cylinder ratios of the triple are 1 : 2·04 : 6·54, and for the quadruple 1 : 2·08 : 4·46 : 10·47. It will be noted that, according to the diagram, the volume of the low-pressure cylinder is the same for both engines. It is probable that actually the low-pressure cylinder of the quadruple will have a greater volume; this, however, will not introduce any appreciable error into the calculations.

For facility of comparison, let us take as an example a triple-expansion engine of $\frac{28'' \times 40'' \times 71''}{48''} \times 150$lb. pressure; revolu-

Digitized by Google

tions = 65 = "normal" revolutions of the Institution's Rule, and arrange the corresponding quadruple to develop the same horse-power. The first point is to decide upon the stroke of the quadruple. It will be of advantage to keep the stroke as long as possible, as the longer the stroke the greater the piston speed with "normal" revolutions; besides which long strokes and consequently small diameters of cylinders will save space longitudinally, the height of the engines being in merchant vessels generally of little consequence. Let the stroke of the quadruple, then, be taken at 48in., the same as the triple. To determine the number of revolutions, let it be assumed that the engines can be run safely and smoothly when the initial pressure is equal to the pressure required to absorb the inertia of the reciprocating parts at the end of the stroke, and when there is a margin of pressure, always keeping the slipper on its guide.

Let w = weight of reciprocating parts per square inch of piston.
n = number of revolutions per minute.
r = radius of crank in feet.
c = length of connecting rod in feet.

The weight of the reciprocating parts per square inch of piston will probably be:—

For 1st cylinder = 7·5lb. per square inch.
,, 2nd ,, = 4·0lb. ,, ,,
,, 3rd ,, = 2·5lb. ,, ,,
,, 4th ,, = 1·8lb. ,, ,,

The pressure per square inch of piston required to accelerate the reciprocating parts at the beginning of the stroke:—

$$p = \cdot00034 \times w \times n^2 \times r \times \frac{C \times r}{C} - w \text{ for top centre.}$$

$$p = \cdot00034 \times w \times n^2 \times r \times \frac{C - r}{C} + w \text{ for bottom centre.}$$

In our case:—

p = 146·0lb. per square inch for 1st cylinder.
= 70·0lb. ,, ,, 2nd ,,
= 32·5lb. ,, ,, 3rd ,,
= 14·0lb. ,, ,, 4th ,,

Limit of revolutions—

1st cylinder	top	156	revolutions.
	bottom	188	,,
2nd cylinder	top	148	,,
	bottom	178	,,
3rd cylinder	top	104	,,
	bottom	151	,,
4th cylinder	top	401	,,
	bottom	115	,,

This practically limits the revolutions to 100 per minute.

No account has yet been taken of the inertia of the pumps. If the pumps are worked off the fourth cylinder, the revolutions must be reduced, if the pressures in the pumps themselves are not sufficient to overcome the inertia of the moving parts.

For the second cylinder—

$$p = 70 = \cdot00034 \times w \times 100^2 \times 2 \times \frac{10·5}{8·5} - 4.$$

$$w = \frac{74 \times 8·5}{\cdot00034 \times 100^2 \times 2 \times 10·5} = 8·8\text{lb. per square inch of piston.}$$

Weight of piston, connecting rods, &c. = 4lb. per square inch of piston; so that the steam in the second cylinder would balance 8·8 − 4·0 = 4·8lb. of pump gear per square inch of second cylinder = ·95lb. per square inch of fourth cylinder. The actual unbalanced inertia will probably not be more than this, so that the engines can still be run at 100 revolutions if the pumps are driven from the second cylinder.

We have next to consider the other limit of revolutions—viz., the momentum due to the transverse motion of the connecting rod. This has been estimated in the following manner:—The path described by the centre of gravity of the connecting rod being traced out, an arc of a circle is found which will coincide as nearly as possible with the curve at half stroke. The centre of gravity of the rod is assumed to be rotating on the radius thus found. This is, perhaps, not a strictly accurate solution of the problem, but will be sufficiently near for the present purpose. In the case under consideration the weight of the connecting rod proportioned for a 71in. cylinder = 2,100lb.; length = 8ft. 6in.; centre of gravity, 43in. from bottom end; radius of arc coinciding with path described by centre of gravity at half stroke = 3·6ft.; so that the centrifugal force exerted by the rod will be—

$$\cdot00034 \times 2{,}100 \times 100^2 \times 3·6 = 25{,}700\text{lb.}$$

This is equivalent to 10,400lb. acting at the cross-head.

The pressure on the guides

$$= \frac{\text{Area } 71'' \times 14 \times 2}{8·5} = 13{,}000\text{lb.};$$

so that at 100 revolutions there is still a margin of 2,600lb. to keep the shoe on the guide.

Assuming that, by the increased working pressure and increased piston speed, an economy of, say, 10 per cent. can be effected, the size of the low-pressure cylinder of the quadruple to develop the same indicated horse-power as the triple we have taken as an example, will be—

$$\frac{\text{Area } 71'' \times ·9 \times 65}{100} = 2{,}316 \text{ square inches} = 55\text{in. diameter.}$$

The cylinder ratios, as determined before by the diagram, Fig. 3, are 1 : 2·08 : 4·46 : 10·47, so that the quadruple engines will be—

$$\frac{17'' \times 24\tfrac{1}{2}'' \times 36'' \times 55''}{48''} \times 250\text{lb. boiler pressure.}$$

Revolutions per minute = 100.

The size of the triple engine which it is to replace being—

$$\frac{28'' \times 40'' \times 71''}{48''} \times 150\text{lb. pressure.}$$

Revolutions per minute, 65.

To sum up, the writer has endeavoured to show that the economy of the three-crank triple-expansion over the two-crank compound has been mainly due to the increase of boiler pressure, and, to a small extent, to the increase of piston speed. That by increasing the boiler pressure to 250lb. per square inch a steam economy of, say, 15 per cent. can be obtained over the present three-crank triple. That an increase of piston speed, besides increasing the economy of steam, will also increase the weight

HIGH PRESSURE BOILER FOR MARINE PURPOSES.

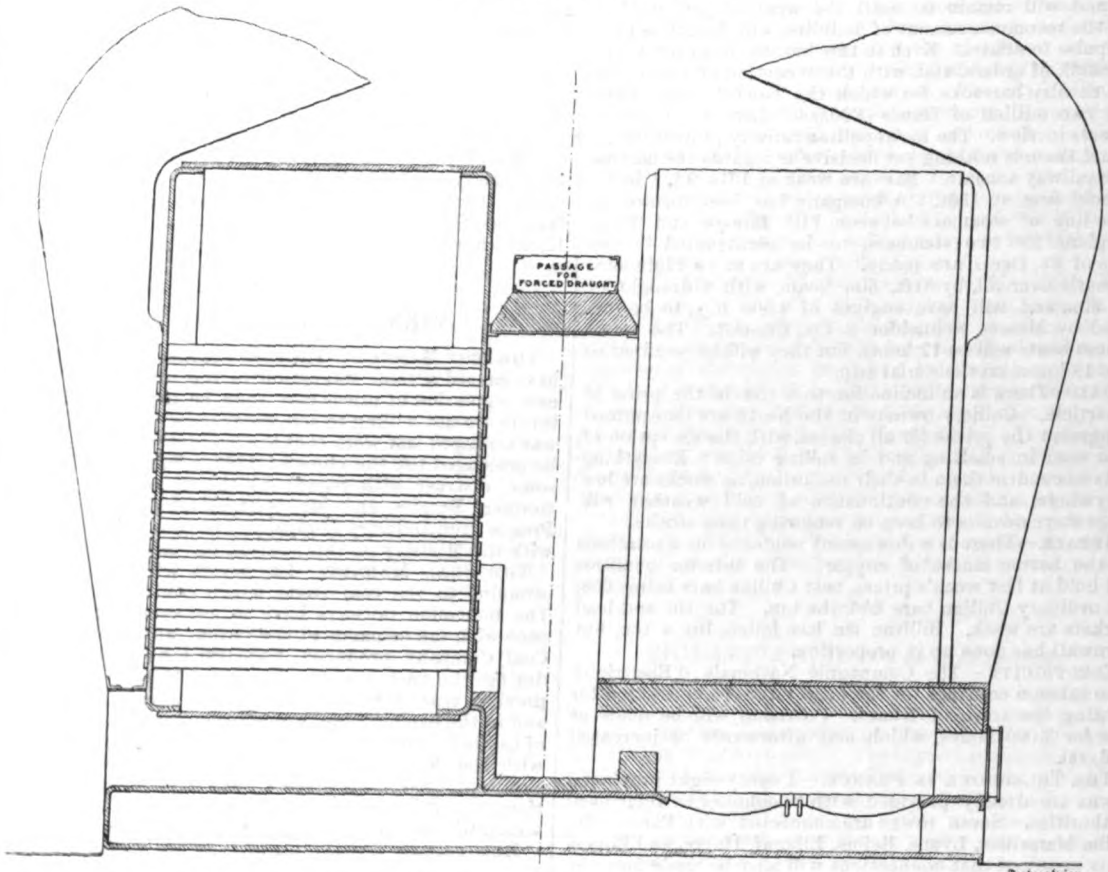

FIG. 4.—SECTION THROUGH BOILER.

FIG. 5.—SECTION THROUGH FURNACE.

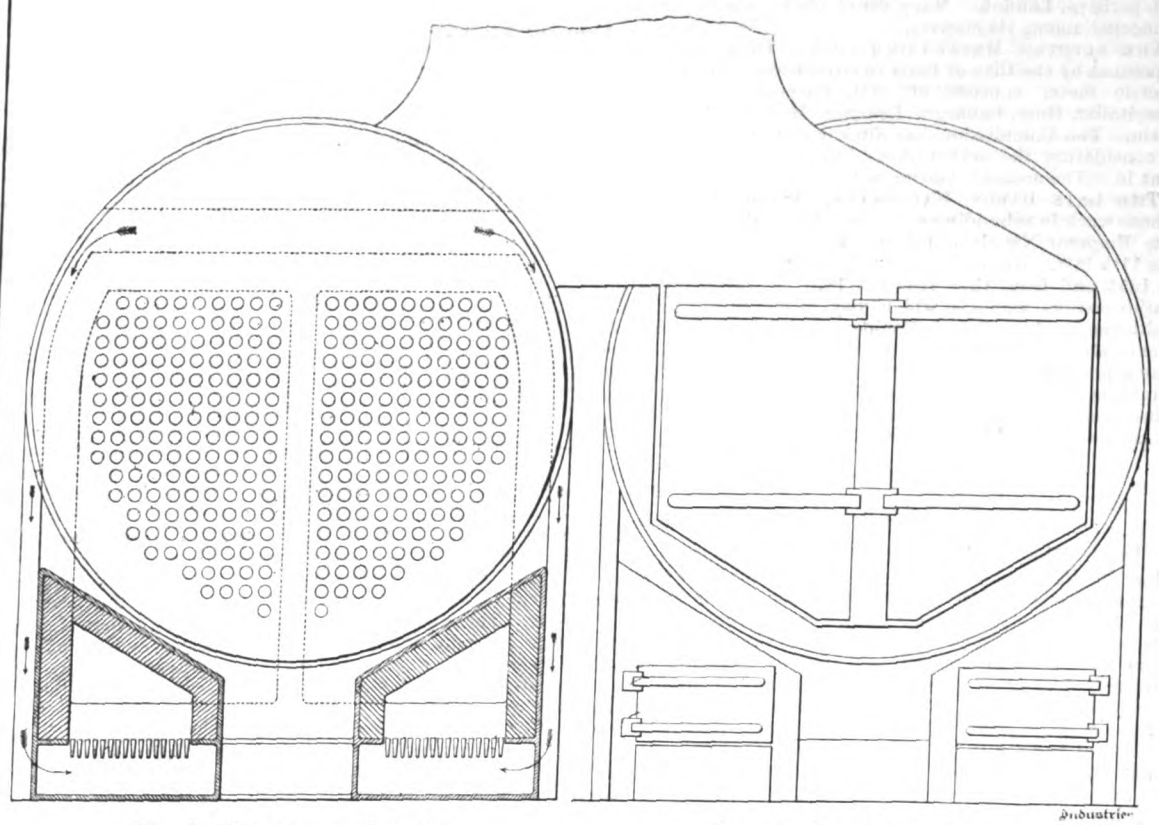

FIG. 6.—TRANSVERSE SECTION.

FIG. 7.—END ELEVATION.

economy, so that the piston speed should be increased up to the limits set down in the paper. That the best type of engine to use this higher pressure, and best adapted to run at a high speed, is the four-crank four-cylinder engine, with unjacketed cylinders and separate steam and exhaust valves.

Passing on to the question of the type of boiler to be adopted, the writer is of opinion that a considerable departure from the present design of boiler is necessary, in order to make a satisfactory structure for 250lb. pressure. With this pressure difficulties will arise with the furnaces, and the flat sides of the combustion chambers. To get over these difficulties the writer proposes to put the furnaces and combustion chambers outside the boiler altogether. The boiler then become a simple cylinder, the tubes running from end to end. As shown in Figs. 4, 5, 6, and 7, the boilers are arranged back to back, with the combustion chambers between them. The furnaces and combustion chamber may be of cast or wrought iron, lined with firebrick. In order to keep down the grate surface, and thus economise space athwartships, it will be of advantage to use forced draught, and all the air on its way to the furnaces is made to pass over the top and sides of the combustion chamber, thus reducing to a minimum any loss from radiation.

The advantages of a boiler of this type are obvious. It is perfectly suitable for a high pressure. There will be no straining from unequal temperatures. The cost of manufacture will be considerably less than that of the present type of boiler. For the same heating surface the space occupied is less; the boiler shown in Figs. 4, 5, 6, and 7, is 10ft. 6in. diameter, and contains the same heating surface as a boiler of the present type 13ft. 6in. diameter, the lengths in both cases being the same.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 13th January, 1891.

Iron.—The iron market is still in a state of stagnation here, and will remain so until the weather gets milder, when the recommencement of building will doubtless give an impulse to affairs. Even in this branch, however, there is a dearth of orders, and, with the exception of some proposed cavalry barracks, for which the Town Council have voted two million of francs (£80,000), there are no large contracts in view. The metropolitan railway project hangs fire, and there is nothing yet decisive as regards the narrow gauge railway scheme. Bars are weak at 131s. 9d.; joists still hold firm at 136s. A company has been formed to run a line of steamers between l'Ile Rousse and Nice. The plans for two steamers, to be constructed in the works of St. Denis, are ready. They are to be 229ft. 6in. in length over all, by 31ft. 6in. beam, with a draught of 11ft. 9in., and will have engines of 2,500 h.p., to be furnished by Messrs. Schneider & Co., Creuzot. The speed of these boats will be 17 knots, but they will be required to make 19 knots on their trial trip.

Coal.—There is an inclination to a rise in the price of this article. Colliery owners in the North are determined to augment the prices for all classes, with the exception of those used in smelting and in rolling mills. Everything tends to confirm them in their resolution, as stocks are low everywhere, and the continuance of cold weather will oblige store owners to keep on renewing their stocks.

Metals.—There is a downward tendency in quotations for the better marks of copper. The inferior qualities still hold at last week's prices, best Chilian bars being £58, and ordinary Chilian bars £56, the ton. The tin and lead markets are weak. Billiton tin has fallen 10s. a ton, but Cornwall has gone up in proportion.

Electricity.—The Compagnie Nationale d'Electricité have taken a contract for the installation to be erected for lighting the town of Nimes. Provision will be made at first for 2,000 lamps, which may afterwards be increased to 6,000.

The Telephone in France.—Twenty-eight provincial towns are already provided with telephones by their local authorities. Seven towns are connected with Paris—viz., Lille, Marseilles, Lyons, Reims, Elbœuf, Havre, and Rouen. It is expected that connections will also be made between Paris and Troyes, Paris and St. Quentin, Paris and Amiens, Arras and Lille, Paris and Orleans, and Paris and Brussels, and, perhaps, London. Many other towns are or will be connected among themselves.

The Electric Meter Commission.—The Commission appointed by the City of Paris to adjudicate as to the best electric meter consists of MM. Carpentier, Chrétien, Hospitalier, Huet, Laffargue, Lemoine, Mascart, Meyer, and Potin. The Commission has already begun its work, and is considering the seventy-one different kinds of meter sent in. The accurate testing will be carried out later.

The Late Baron Haussmann.—Baron Haussmann, whose work in rebuilding and beautifying Paris under the late Emperor Napoleon III. is well known, died here on the 11th inst. He was summoned to Paris by the Emperor in 1853, and from that year till 1870 he was engaged in various works, amongst which may be mentioned the embellishment of the Bois de Boulogne and Bois de Vincennes, the establishment of public gardens, the prolongation of the Rue de Rivoli, the construction of new boulevards, the building of barracks, churches, bridges, markets, fountains, theatres, and the new Opera House. A boulevard, which was named after him, still retains its name.

BERLIN, 12th January, 1891.

Iron.—The year 1891 opens with brightening prospects for the iron trade of this country. In spite of the hindrances caused by the exceptionally cold weather, business is increasing. To what extent the revival will proceed it would be rash to predict. The activity of last year is not likely to be soon repeated, but, from present indications, we may reasonably expect a good average year with fairly remunerative prices. From both the Upper Silesian and the Rhenish-Westphalian districts come more favourable reports of the state and tendencies of the markets. The demand has in some degree revived for both crude and finished iron, and seems likely to become brisker as the spring approaches. Prices are firm. The following list of prices of forge pig and merchant bars current at the end of each month in 1890 shows the general movement of the iron markets in the Rhenish-Westphalian districts in that year:—Rhenish-Westphalian best forge pig, 92s., 92s., 91s., 78s., 78s., 72s., 72s., 68s., 62s., 58s., 58s., 58s. a ton; bars, 195s., 205s., 205s., 205s., 185s., 185s., 170s., 170s., 145s., 140s., 135s., 135s., 135s. a ton. From statistics just published to show the continued and rapid development of the iron industry in Germany, we learn that the number of hands employed in that industry increased from 183,874 in 1873 to 192,625 in 1883 and to 223,091 in 1889. In consequence of the adoption of improved processes and more efficient machinery, the number of hands employed about the blast furnaces have, in the period in question, notwithstanding a large increase in the production of pig, diminished considerably, being 23,985 in 1889, against 28,129 in 1873.

Metals.—The new year has brought no improvement in the metal market. The amount of business done is very small, and consists only of transactions to meet the most pressing needs of the moment. Of purely speculative business, there is absolutely none. Copper is, however, somewhat firmer in price. Mansfeld refined is quoted £69 to £72 a ton, English brands from £55 to £67. Tin is still weak. Lead is unaltered in price, but the tone of the market is languid. Spelter shows a downward tendency. Though no heavy fall in spelter is likely to occur, considerably lower prices will probably be reached before the end of the first quarter of the year. The ordinary Silesian sorts are quoted £25 5s. to £25 15s. a ton. Antimony regulus is fairly firm.

The Dynamite Syndicate.—The German and International Price Convention for Dynamite, which expired with the year 1890, has been revived for a number of years. Two hitherto outstanding firms of dynamite manufacturers, the Geyer Erzgebirgische Dynamitfabrik and the Kosmos Sprengstaff-Gesellschaft, have joined the syndicate.

VIENNA, 12th January, 1891.

The Iron Market.—The cold weather and the holidays have caused a total stagnation in the iron market. As a new regulation of prices may soon be expected, manufacturers are not willing to sell under present conditions. It was arranged last week that the bar iron syndicate should be prolonged till the close of 1893. Manufacturers show some distrust with regard to the agreement with the German Empire, and Mr. Wittgenstein, director of the Prague Iron Industry Company, who was asked to confer with the Ministry on this subject, has refused to do so.

The Coal Market.—The severe winter has given a stimulus to the coal trade, which continues very brisk. The Bohemian railways have to use every effort to keep pace with the demands of the various works. The Brüxer Coal Company produced 1,500,000 tons of brown coals during the past year, as against 1,100,000 tons in the previous year. Generally there is an increase in production and in the export trade, which encourages the investment of capital. The Credit Bank is carrying on negotiations with the Northern Railway for its coal mines. Baron Rothschild has lately given a fresh impulse to the negotiations, and it is expected that a joint-stock coal company which will be the largest in Austria will soon be formed.

Electrical Engineering.—As we have already announced in our report of last week, the International Electricity Company intends to erect a large installation in the centre of the city for the purpose of lighting the new Government printing offices. The installation will provide current for 2,000 incandescent lamps of 16 candles, and will differ from the other central stations erected by this company in its being on the continuous current system. The dynamos consist of three machines of the Ganz type, Δ 4½, and one of the type Δ 3. The engines for this installation are provided by the Brünner Machine Manufacturing Company on the design of Professor Radinger, whilst the laying of the entire system of conduits has been entrusted to Messrs. Brückner, of Vienna.

BRUSSELS, 13th January, 1891.

Iron.—The state of the iron market still leaves much to be desired. There is but little business doing, and to get this little sellers are compelled to make further concessions in prices. Manufacturers are asking 112s. a ton for No. 2 bars, but consumers refuse to pay more than 105s. The outlook, though somewhat less gloomy than it was a month ago, is sufficiently discouraging. More blast furnaces are to be blown out at the end of the present month. This unsatisfactory state of things is due principally to two causes—the great advance in the prices of coal and coke, and the collapse of business in South America. The exports of Belgian iron to that part of the world in the first eleven months of 1890 amounted to only 17,956 tons, against 52,039 tons in the corresponding period of the previous year. There has also been a somewhat serious loss of trade with Holland, where our business in plates has suffered severely from English and German competition. This loss is largely attributable to the augmented cost of production due to dear fuel.

Coal.—There is no abatement of the activity which has so long characterised the coal market of this country. The slackened demand for metallurgical uses, consequent on the depression in the iron trade, has been compensated for by an exceptionally brisk demand for the household sorts, caused by the severe weather of the last five or six weeks. Prices have again an improved tendency. Small coal for coking is scarce, and cannot be bought for less than 9s. 6d. a ton. Coke is nowhere offered at less than 14s. 6d. a ton. German competition continues keen; but the conditions of trade are now such that prices of Belgian coal are but little affected by it. There is no prospect of cheaper coal for at least some months to come.

Glass.—The year 1891 begins badly for the glass industry. Business is very slack, and the circumstances of trade are such that no great improvement is likely for some time to come. The market is depressed in tone. Though the trade is suffering from over-production, new works are coming into operation, and great projects are talked of. The new works of St. Roch Auverlais started successfully on New Year's Day.

DÜSSELDORF, 13th January, 1891.

Coal and Iron.—The general situation of the Westphalia coal market is much influenced by the abnormal state of the weather. The extensive inundations of the Ruhr, which took place in the second half of November, by which many important railway lines were interrupted, were the first cause of a good deal of the irregularity in the shipment of the coal and coke. The severe weather then suddenly set in, which, while it increased the consumption of coal for domestic purposes, decreased at the same time the capacity of the railways, as heavy snowslips accompanied the frost. Many of the coal pits were forced to lie idle two and in some cases even three days during each of the past weeks, and the decrease in the production caused in this way is estimated to be already about 1½ per cent. of the annual output. Of course, there prevails a strong demand for coal, and prices are rising. The quotations are for gas coal, per ton of 1,000 kilogs., 9·50 to 12 marks; cleaned coal for coking, 7·50 to 8 marks; and for coke, 14·50 to 15 marks. The ore market is quiet. Somorostro ore is at 15 marks f.o.b. Rotterdam, and French magnetic ore, containing about 60 per cent. of iron, is being much offered. The pig iron market is steady, and consumers of foundry pig are keeping back, as the Glasgow and Middlesbrough prices are lessening. German foundry No. 1 is quoted at 75 marks; No. 3, at 63 marks; while Luxemburg foundry is at 52fr. at Luxemburg. Hematite is at 75 marks; German Thomas pig at 49 marks. The bar iron market is quiet, as is usually the case at this season. The prices of sheets and boiler plates are declining; Siegen sheets are at about 135 marks. The German manufacturers are deeply struck by the fact that the Bavarian railways and the Prussian State Railway direction of Magdeburg have taken a supply of 8,000 tons of steel rails from their English competitors. They have made up an estimate, according to which the costs involved by the new Social laws are about 5½ marks per ton of rails, and they regard it as the duty of a Government which imposes those heavy charges on the home industries to take their supplies from them, even if they ask somewhat higher prices than those of foreign firms.

Bridge Building.—The Harkort Works in Duisburg have received the order to supply three bridges for Roumania of the total value of about 1,000,000 marks.

AMSTERDAM, 12th January, 1891.

The Weather and Navigation.—The severe weather continues unabated all over Holland, and the frost has been intense. In the country there is no water, and the towns are little better off. In Amsterdam alone it is computed that 8,000 families have their supplies cut off through the water pipes freezing. The Down Water Company has stationed men with huge bells, which they keep ringing incessantly, around the principal hydrants in the streets, where water is supplied free of cost to all comers. Of course navigation nearly everywhere is at a standstill. But Rotterdam offers in this respect a striking contrast to Amsterdam. There has been very little ice trouble in the New Waterway, whilst Antwerp is virtually a closed port, and ocean vessels have been able to reach Rotterdam and to depart from it without let or hindrance, the impediments of ice floes only commencing above the two Maas bridges. On the other hand, Amsterdam is still unapproachable from the sea, along a canal only some miles long. Huge steamers are stuck fast in the middle of it, and either cannot advance or only get on at the pace of some ancient slave galley. This is notoriously the case with the mail steamer "Koningin Emma," of the Nederland Company, which steams up to Amsterdam at the rate of a thousand metres a day. The canal being 23,000 metres long, it will take the ship the best part of a month before it is safely berthed alongside the quay in Amsterdam.

The Ice on the North Sea Canal.—At the town side of the canal 200 workmen are busily engaged in sawing a swinging space and a channel for the outgoing mail steamer, the "Prins van Orange," of the same company. The ice here has a thickness of 50 centimetres. It is sawn into blocks, each weighing about one thousand kilogrammes, and it requires the united efforts of thirty men to handle every block and carry it away over the ice. It goes without saying that these operations are most expensive, and if a railway existed to Ymuiden it would have its carrying power taxed to the utmost. But the Government is blamed for not having undertaken this line, and for neglecting to provide for an efficient ice service upon the North Sea Canal. The officials say, no doubt, that they have nothing whatever to do with the ice service. The North Sea Canal Company held a concession for the purpose, the condition being that the company should keep the canal open and charge "ice dues" to all vessels using the waterway during the winter months. The company, however, ceded its special concession to a subsidiary company, the Ysploeg, an arrangement which the State could not alter when it took over the canal. But the Ysploeg failed after a few iceless winters, and now the ice surface is not maintained by anybody. The Government could surely see to the concession being carried out, and cancel it when it was not carried out. Yet all it will do now is to experiment with powder, dynamite, and other explosives, against the solid ice crust before Amsterdam.

Trade with Antwerp *vid* Flushing.—The closing of Antwerp has benefited Flushing immensely, and all the large ships that cannot proceed up the Scheldt are now

Digitized by Google

making for Flushing, where goods are placed in special trains and despatched to Antwerp. Flushing, which at other times is rather sluggish, at this moment offers a curious sight of business at fever-heat. The harbour is full of steamers, and six to eight more are arriving every day. Among the latest arrivals are the "Sheldrake," from Liverpool, and the "Belgenland," from New York, the latter a Red Star Liner.

PETROLEUM AT ROTTERDAM.—The Municipal Council of Rotterdam has approved the Bill to build a connecting line between the nearest railway station and the petroleum depôt at Charlois. The petition of the inhabitants of Charlois to have a movable bridge instead of a fixture was not acted upon, on account of the greater cost.

STOCKHOLM, 10TH JANUARY, 1891.

IRON IN STOCK.—The quantity of iron upon which the Riksbank has advanced loans in Stockholm and in Gothenburg was considerably less at the end of last year than at the beginning, which will appear from the following particulars. At the head office in Stockholm the quantities were :—

	Kilogrammes.
Pig iron	11,449,821
Bar iron	3,601,833
Ingots of Bessemer and Martin steel	5,940,512
Other kinds of iron	3,863,541
	24,855,707
and at Gothenburg—	
Pig iron	5,334,429
Bar iron	2,882,262
Ingots of Bessemer and Martin steel	403,879
Other kinds of iron	2,449,026
	11,069,596

The aggregate sum advanced upon the above was 2,561,639kr., of which 1,747,049kr. were in Stockholm and 814,590kr. at Gothenburg. During the last three months of the year the quantity has been steadily increasing :—

	Kilogrammes.
October 31st	33,203,134
November 30th	34,347,968
December 31st	35,925,303

The quantity at the end of the year was thus about 36,000 tons, against 45,000 tons at the beginning of 1890.

THE ZONE TARIFF IN SWEDEN.—The zone tariff was in the course of last year introduced at the Uddevolla-Herrljunga Railway. The manager reports that it works very well; there is an increase in revenue and a large increase in the number of travellers.

THE HERRING FISHERIES.—The herring fishing on the West Coast has proceeded satisfactorily enough from about the middle of November, and the quantity of herrings salted at Norrviken up to the end of last year amounts to some 72,400 barrels. The fishing at the Bohnslön Skögord has been satisfactory; considerable quantities of salted herrings have been exported to Russia and Germany, and of fresh herrings a large quantity has been sent to Germany.

CHRISTIANIA, 10TH JANUARY, 1891.

THE TIMBER INDUSTRY IN 1890.—The fair promises with which the past year opened have not been fulfilled, and there has been a sudden and almost unprecedented fall in prices. The main reason for this great fall is, no doubt, over-production, and it is to be sincerely hoped that a movement similar to those which have already resulted in a sensible and wholesome reduction of output in other industries may succeed in the timber industry. The over-production of timber during 1890 has not resulted in an excess in the exports above those of the previous year. Though full particulars for November and December are not yet available, it is estimated that the total export for last year from Norway is likely to be about 1,850,000 cubic metres, against 2,021,541 cubic metres for 1889, which shows a decline for the year 1890 compared with the previous year of about 8½ per cent. Up to the end of October last year the aggregate exports of timber amounted to 1,688,357 cubic metres, of which Great Britain and Ireland account for as much as 1,028,503 metres; next comes France, with 147,057 cubic metres; Holland, with 114,726 cubic metres; Belgium, with 102,891 cubic metres; and Australasia, with 100,898 cubic metres. The balance has gone to Germany, Sweden, Denmark, and Spain. The value of last year's timber exports has been put at 32,000,000kr., against 37,000,000kr. for 1889. Last winter floating down conditions were favourable, and the timber came quickly forward. As little has been sold for forward delivery, and as the present owners do not appear to be in want of money, only little will probably be floated down this winter. There must, besides, be good stocks, as the cuttings of last year exceeded those of the previous year, whereas the exports, as already stated, were smaller. The large stocks in Norway, as well as in Sweden and Finland, and especially in these two latter countries, must have a material bearing upon the industry for the present year. It is thought that the more immediate effect of the admittedly large stocks will be unaltered low prices for timber for spring shipment, although it is not unlikely that an improvement may set in later on, on account of the reduction in this winter's production. On the whole the prospects for the Norwegian timber industry are not particularly bright, but the producers have to some extent the matter in their own hands. Whether sufficient co-operation between the Scandinavian timber producers can be brought about to ensure that regulation in the output which is necessary to regulate the prices, the future only can show.

COPENHAGEN, 10TH JANUARY, 1891.

INDUSTRIAL NOTES FROM ICELAND.—Last year was a fairly good one for Iceland, although the cod fishing in some parts has not been satisfactory. There has been no Greenland ice, and the weather has been tolerably good. Of train oil the exports from Iceland to Copenhagen amounted to about 9,000 barrels, which is about 800 barrels less than during 1889. The prices were at first rather low, but improved, especially towards the end of the year. Of dried fish (Klipfisk) some 6,085,000lb.(D.) were exported from Iceland to Copenhagen, and the export direct from Iceland amounted to 6,846,000lb.(D.) The export of dried fish from Iceland direct to Genna amounted to 1,268,000lb.(D.), and for the Spanish market amounts to 4,745,000lb.(D.) The production of wool was comparatively good; the exports direct to England amounted to about 320,000lb.(D.), whereas about 1,000,000lb.(D.) were exported from Iceland to Copenhagen, showing an increase of 157,000lb. as compared with 1889. The export of salted sheepskins amounted to 8,780 bundles, which was about 1,100 bundles less than that of the previous year. The export from Iceland to Copenhagen of cleansed eider down was 5,000lb.(D.)

THE COPENHAGEN BREWERIES.—The amalgamation of about a dozen Copenhagen breweries, to which reference was made in a previous letter, has not yet been definitively completed, one of the breweries in question having recently put some difficulties in the way. The result was a sudden drop of 10 to 12 per cent. in the price of the shares of one of the largest breweries, but it is still hoped that the matter may be arranged.

MADRID, 12TH JANUARY, 1891.

THE BILBAO SHIPBUILDING YARDS.—Some comments have been made on the first announcement that the contract for the building of the three large cruisers, which was undertaken by Messrs. Martinez Rivas & Palmer, is to be transferred, with the consent of the Spanish Government, to a public company. This company will be called the "Astilleros del Nervion," and will have a capital of £1,200,000. The largeness of the capital seems to imply that the whole of the Martinez de las Rivas business, which was originally formed by the Marquis de Mudela, is to be included in the new company. The property consists of iron ore mines, four blast furnaces, coal mines in Asturias, a battery of coke ovens (which is nearly finished), shipbuilding yards, engineering and armour plate shops, and a large steam plant. Some suppose that the change has been effected in order to enable Signor Martinez to become a member of the House of Commons (Cortes), as the transaction of business with the Government in his own name was a disqualification. Others say that the limited company has been formed with the object of relieving Signor Martinez and Sir Charles Palmer of their personal liability.

VINE DISEASE IN THE PROVINCE OF CORDOBA.—The vine disease has appeared in the province of Cordoba. The valuable wine known in the market by the name of Montilla, although much of the wine so named is not made in the vicinity of that place, is grown in this province. The celebrated Xerez wine called Amontillado gets its name from its having some resemblance to the true Montilla.

TELEPHONES.—The bye-laws for the carrying into effect of the decree which deals liberally with private telephone enterprise were published on the 6th inst, It remains to be seen how far these liberal provisions will be carried out in practice. Licences are to be readily granted for private lines at an annual payment of 4s. for each kilometre of line. This should be a great inducement for some company to establish itself for the purpose of erecting these private lines.

NEW YORK, 3RD JANUARY, 1891.

METROPOLITAN TRACTION SYSTEM.—The Metropolitan Traction Company, of New York City, which is now engaged in substituting the cable system for horse-power in Broadway, is about to increase its capital stock from $10,000,000 to $20,000,000, to raise money for the completion of the improvement. Present stockholders may subscribe in proportion to their present holdings, but must pay $2·50 per share as earnest money and 15 per cent. of the par value of the stock on January 15th, and by the 15th inst. must have paid 60 per cent. as called for. This company owns six of the important lines in the city, besides several smaller ones. By introducing cable in Broadway it will do away with the 2,000 horses now employed on the line, and at the same time be able to handle its enormous business with greater satisfaction to the public. The carrying capacity of the cable road will be 600,000 passengers per day, and it is calculated that at least half this number will be carried.

WINDOW GLASS.—An attempt is being made to put the American Window Glass Company, the big trust recently formed by the manufacturers, into active operation. Dealers expect that one result will be an increase in prices, and are placing orders for future delivery at present prices. Objections from factories in Ohio and Indiana have prevented an earlier commencement of business by the new company. Recently there has been a deficiency of gas, which has necessitated the closing of several of the factories, and has had the effect of bringing them into conjunction with the combination. The advance in fuel in Pittsburgh on the first of last month, amounting to about 30 per cent., will not close any of the establishments, as they cannot afford to shut down now long enough to rearrange their furnaces for coal. The rate for natural gas which will prevail during the present year will be higher than the equivalent in coal, but it is probable that the companies will continue to use it, because of the excellence of the gas-fired glass.

NAVAL AFFAIRS.—The contract for building the harbour defence ram, at a cost of $930,000, has been given to the Bath Iron Works, of Bath, Maine, the president of that company having agreed to withdraw his stipulation for the omission of the clause providing for the rejection of the vessel if she should fail to make 17 knots per hour. The cruiser "Newark" has returned, having successfully completed her trial trip under the Navy Board. The required horse-power was 8,500, and, although detailed returns have not yet been made, it is probable that she has earned for her builders a premium of something over $40,000, at the rate of $100 per each horse-power in excess of the power required. The speed from the logs showed an average of 19·7 knots, and at one time, for two hours, the average was 20·4 knots.

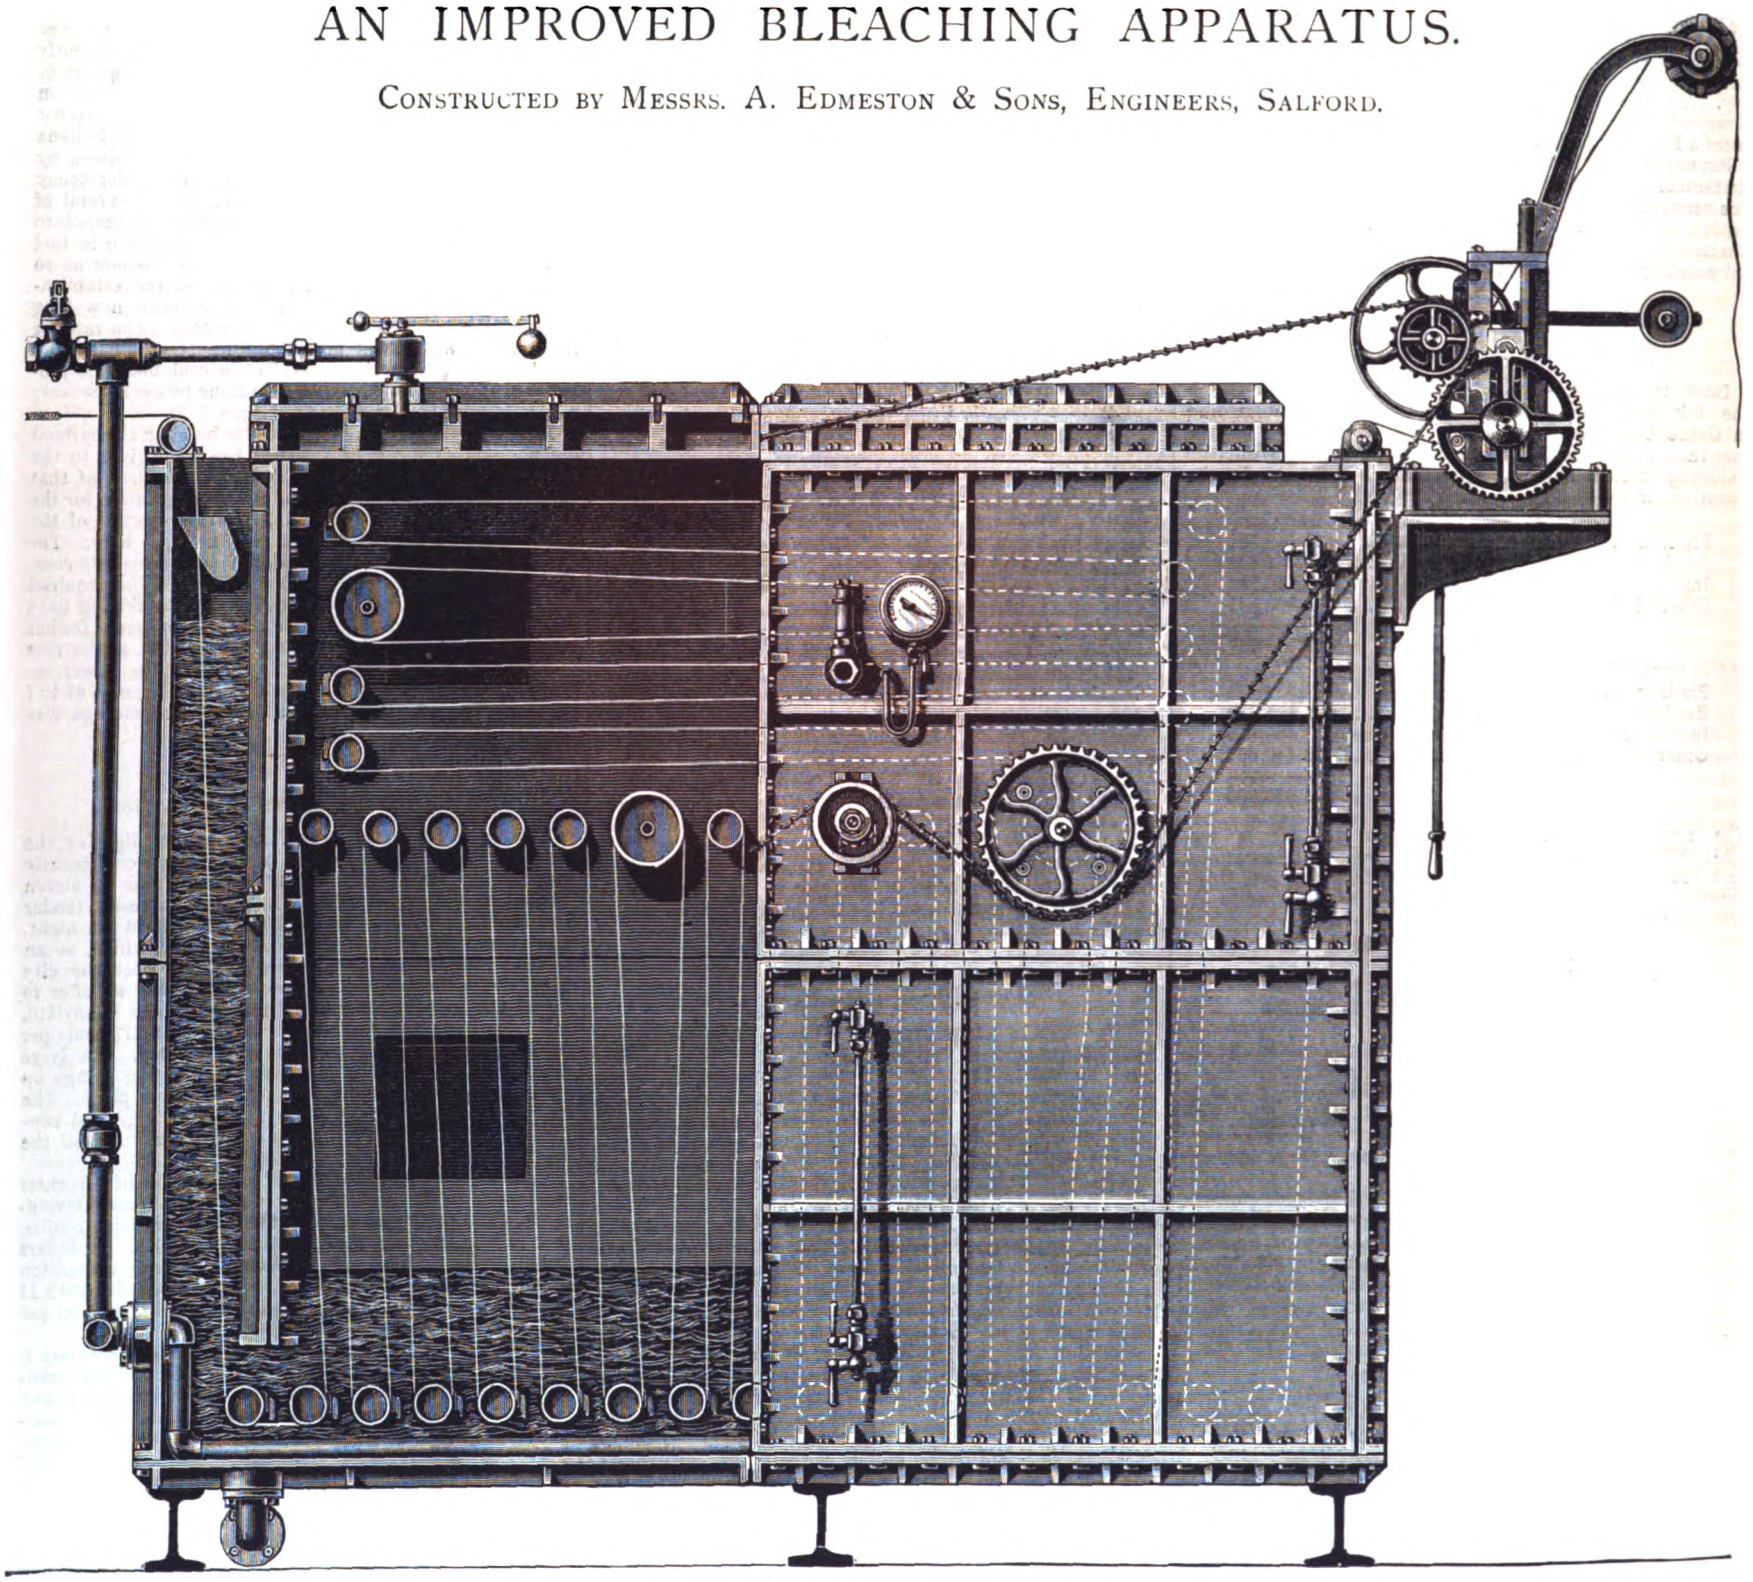
PHILADELPHIA, 2ND JANUARY, 1891.

ELECTRIC LIGHTING.—The contracts for lighting the streets of Philadelphia for the present year were recently awarded by the Department of Public Works to eleven different lighting companies. The highest successful tender was 55 cents, and the lowest 30 cents, a light per night. The total number of lights is about 1,472, which, at an average rate of 43½ cents per night, will cost the city $234,000 for the year. The lowest tender was an offer to do all the lighting from the Delaware to the Schuylkill, and from Lehigh to Washington Avenues, at 27½ cents per night after April 1st, but this was rejected. The large amount which must be paid for city lighting brings up again the question of the city owning its own plant. The city now has access to over 600 miles of underground conduits, and it is estimated that plant sufficient to do all the lighting could be erected for $600,000.

CARPENTER STEEL.—A test of some samples of Carpenter steel made at Reading, Pa., for the United States Government, was recently made, and gave rather surprising results. One of the 1in. bars tested broke at 233,000lb. per square inch, the elastic limit was 194,000lb., and the elongation was 7½ per cent. A second bar broke at 170,000lb., with 11 per cent. elongation, and a third at 139,000lb., with 20 per cent. elongation.

WIRE MAKERS.—A conference of wire manufacturers is in session in Pittsburgh, the object being to devise means of curtailing the output of the mills and to advance prices. It is denied that a trust is in contemplation. The manufacturers claim that the business has been run at starvation prices, owing to ruinous competition. The conference will last several days. Every large wire mill in the country is represented.

STEEL RAILS.—There is considerable dissatisfaction felt by steel manufacturers concerning the allotment of rails during the past year. Two meeting were held during December, but with no results. The trouble began last summer, when the Lackawanna Iron and Steel Company, after asking in vain for a meeting with a view to getting a larger allotment of rails, finally made the additional quantity of rails that it claimed to be entitled to. The dull period followed, and after the Allegheny Mills had been bought by Messrs. Carnegie, strong efforts were made to unite the trade. The trade is now in a most unsatisfactory condition. This is a dull season of the year, and the railroads are ordering very few rails. Many concerns are without money, and, in the case of new roads, rails cannot be bought with bonds.



STRIKE AT CARNEGIE'S WORKS.—Between 400 and 500 Hungarians, employed at the blast furnaces of Mr. Carnegie's Edgar-Thomson Steel Works, struck work on the 31st ult., which will cause the works to shut down and throw about 3,000 men out of employment. The existing scale of wages would have expired on the 1st inst. A new scale was presented on October 1st, but the firm declined to sign it. In it the men have asked that the hours of work should be reduced from twelve to eight hours, and that there should be an advance of 10 per cent. in wages. The scale was again presented on the 27th ult. at the city offices of the firm, and as the representative of the firm again declined to sign, the men have struck.

COKE FURNACES SHUT DOWN.—The Frick Coke Company gave notice on the 31st ult. that they would shut down 1,100 more coke ovens indefinitely next week, which will throw about 1,200 men out of employment. No reasons are given for the closing. There are now 4,000 idle ovens in the coke region.

AN IMPROVED BLEACHING APPARATUS.

CONSTRUCTED BY MESSRS. A. EDMESTON & SONS, ENGINEERS, SALFORD.

PART SECTIONAL VIEW OF KIER.

AN IMPROVED BLEACHING APPARATUS.

(THE BENTZ PROCESS.)

THE process of preparing cotton goods for dyeing or printing is a very important one, and is usually conducted in cylindrical vessels called kiers, in which a large weight of the fabric is placed and alternately treated by an alkaline solution and steam. This alternate treatment has been shown by long practice to be the best method of extracting from the cloth the various fatty matters which are always contained in it as it is woven. Hitherto the boiling or scouring process has necessitated the filling and emptying of the kiers by hand, and this involved a certain amount of labour and loss of time. Not only so, but the volume of cloth within the kier, and the manner in which it is pressed together, causes a great resistance to the penetration alike of the soda liquor and of the steam, so that the process is one occupying several hours. In most bleach works the steam raising capacity is less than the demand for steam, and it has been the practice to fill and empty the kiers in the daytime and boil them at night, when there is less call for steam than during the daytime. There are thus two facts to take a special note of—1st, that the alternate steeping and steaming of cloth is the best mode of dealing with it, and 2nd, that as hitherto conducted this treatment has been carried out with the cloth in bulk.

We give above a partial sectional elevation of an improved kier which is made by Messrs. A. Edmeston & Sons, Cannon Street Works, Salford, which we have recently inspected at work, and which is based upon the principle of a continuous treatment of the cloth. In addition to the actual kier itself there are several arrangements added to it for feeding and delivering the cloth, to which we shall refer a little later. The cloth enters the kier as shown at the left hand side of the illustration, and is taken downwards through a chamber at the end of the kier proper. The latter is a strong rectangular box, to the interior of which steam is admitted. The soda liquor is fed to the kier from a tank suitably placed, and is maintained at a level, as shown in the illustration, which forms a seal, so that the steam in the interior of the kier cannot blow out. A number of easily running rollers are placed so as to guide the cloth in a zigzag direction from one end of the kier to the other, as is clearly shown by the white lines. At different points three larger rollers are placed, which establish a nip on the cloth and so avoid the excessive strain which would take place if it were dragged along by the rollers at the exit end of the kier. It will be noticed that in its vertical course the cloth passes repeatedly into the soda liquor and the steam space alternately, until, when it reaches the end of the kier, it is passed several times in a horizontal direction in the steam space only, after which it is guided, as shown, down, and then up through a similar compartment to that shown on the left hand or entrance end of the machine. The compartment named is formed by means of a partition extending downwards nearly to the bottom of the kier, and is partially filled with liquor kept at the level indicated by the pressure of the steam. After leaving the kier the cloth is passed between the nip of the squeezing rollers, and is thence carried forward by winces to guide eyes, by which it is deposited in storage boxes or bins preparatory to being taken to the souring apparatus. The plaiting of the cloth in the boxes, which is usually performed by boys, is, in this case, done by a self-acting traverse of the guide eye, derived from suitable mechanism devised by Messrs. Edmeston & Sons.

Digitized by Google

We have inspected the working of this kier at the works of Mr. Peter Reid, Pendleton, near Manchester, where it has been in operation over a period of eight months. It must be noted that the cloth is passed through either in a perfectly open condition or loosely gathered together in a "rope," as it is technically called. In either case two or three pieces can be passed through the machine at a time, and the chief feature of the process is that it is a continuous and not an intermittent one. Further, the treatment of the cloth in this condition allows of the free action of the scouring liquor and steam to a much greater degree than is possible when it is treated in bulk, and it is found that a much larger quantity of cloth is passed through the machine than is possible by any other method of treatment. Not only so, but the quantity of steam required is largely diminished, and, in Mr. Reid's plant, considerably over 200 tons of coal per month are saved by the use of this kier. Nightwork has been completely abolished, as it is found that there is no difficulty in getting all the steam which is required during the daytime, although previously this was not possible. With reference to the quality of the production, an inspection of the cloth shows beyond a doubt that this has not suffered, and an inspection of a very wide and beautiful range of patterns which Mr. Reid was good enough to show us is convincing of the fact that the cloth is in no way damaged, and is, indeed, somewhat better than it was when treated under the older method. It may also be mentioned that during the eight months' working of this kier stained cloth has been practically unknown, and in no single case has there been the rejection of a complete piece. It will be seen that this kier marks a considerable advance upon anything which has gone before, and inasmuch as it has had the very severe test of eight months' continuous working under ordinary conditions, it is, in no sense, an experiment, but has proved itself to be completely efficient. We have no hesitation in saying, that to all bleachers the provision of a method by which they can get continuous instead of intermittent treatment is of high importance, and the kier we have described is worthy of their full attention.

SPANISH SHIPBUILDING.

We understand that Sir Charles Palmer has retired from the firm of Messrs. Martinez Rivas & Palmer, and that arrangements have been made for converting it into a Spanish company by Mr. Martinez Rivas, under the style of Astilleros del Nervion (the Nervion Shipyards), with a capital of £1,200,000. It is further understood that the Spanish Government has consented to transfer their contracts for the cruisers now building from the old firm to the new one. We are afraid that the Spaniards, like others who have recently taken to shipbuilding, are inclined to stand on their own legs a little too early, and may, in consequence, get a few rather disagreeable tumbles.

SHIPBUILDING NOTES.

On the 27th ult. there was launched at Newcastle the sheathed twin steam cruiser "Sybille," built by Messrs. R. Stephenson & Co., of Hebburn, to the order of the Admiralty. This is the third cruiser launched for the home Government on the Tyne during last year, the other two being the "Sirius," launched by Messrs. Armstrong, Mitchell, & Co., and the "Pique," launched by the Palmers' Shipbuilding and Iron Company, Limited. Three more vessels of the same class are in course of construction, and will be launched in the course of the present year.

On the 3rd inst. Messrs. McIlwaine & McColl, Limited, Belfast, launched the s.s. "Manchester," built to the order of Messrs. S. Lawther & Co., Belfast. This is the first steamer for the new line which is to trade between Belfast and Liverpool, and also to Manchester when the Ship Canal is opened. She has been specially designed to meet the requirements of that trade, and her dimensions are:—Length, 180ft.; breadth, 27ft. 6in.; and depth, 13ft. 11in. She is built of steel, and will class 100 A1 at Lloyd's. The new company has a capital of £150,000 fully paid up. Mr. H. S. Lawther will be acting manager, and the agents in Belfast will be S. Lawther & Co., and in Liverpool J. Mack & Sons. The vessels will carry about 650 tons cargo each, and have accommodation for a few passengers. The "Manchester" will start on her service about the 1st prox.

Recently Messrs. Gourlay Bros. & Co., Dundee, launched for the National Steamship Company, of Liverpool, a steamer having a length of 450ft.; breadth, 46ft.; and depth, 35ft. 9in. The vessel is of steel, with cellular double bottom, and a gross tonnage of 5,100 tons. She is fitted with triple-expansion engines, indicating about 3,000 horse-power, and will make about 12 knots an hour. She is intended specially for emigrants and for the carriage of cattle.

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, January 16th, at 7.30 p.m. Students' meeting. Paper to be read: "On a Survey of the Bed of Sutton Pool, Plymouth," by Mr. R. G. Hansford Worth.

Physical Society.—Friday, January 16th. Papers to be read: "Photo-electricity," by Professor Minchin; "A Lecture-room Method of Determining 'g,'" by Professor Bawell; "On the Change in the Absorption Spectrum of Cobalt Glass Produced by Heat," by Sir John Conroy, Bart.

Marine Engineers' Institute, Liverpool.—Friday, January 16th, at 7.45 p.m. Lecture on "The Proposed Museum of Naval Architecture and Marine Engineering," by Mr. B. H. Thwaite, A.M.Inst.C.E.

Junior Engineering Society.—Friday, January 16th. Paper to be read: "Hydraulic Lifts," by Mr. Percy J. Waldram.

Association for the Improvement of Geometrical Teaching.—Saturday, January 17th, at 10.30 a.m. Paper to be read: "On the Use of the Term 'Abstract' in Arithmetic," by Miss Wood. At 2 p.m. Papers to be read: "Another Voyage to Laputa," by Professor Minchin; "The Foundations of Geometry," by Mr. E. T. Dixon; "Some Notes on 'Statics and Geometry,'" by Mr. E. M. Langley.

NEXT WEEK.

Society of Chemical Industry.—Monday, January 19th, at 8 p.m. Papers to be read: "On the Constitution of Butter" (illustrated by specimens), by Mr. J. A. Wanklyn; "Some Experiments on the Cyanide Process for the Extraction of Gold from Low Grade Gold Ores," by Messrs. T. Graham Young and Watson Smith.

Cleveland Institution of Engineers.—Monday, January 19th, at 7.30 p.m. Reply on Discussion of Paper, "On the Desiccation of the Blast in the Manufacture of Pig Iron," by Mr. W. H. Fryer; Discussion of Paper on "The Manufacture of Basic Open Hearth Steel," by Mr. J. Davis; "Notes on American Blast-furnace Practice, and a Comparison with the Work done in the Cleveland District," by Mr. W. Hawdon.

Royal Institute of British Architects.—Monday, January 19th. Presidential Address to Students.

Institution of Civil Engineers.—Tuesday, January 20th, at 8 p.m. Ordinary meeting. Paper to be discussed: "Auxiliary Engines in Connection with the Modern Marine Engine," by Mr. W. H. Allen, A.M.Inst.C.E.

Owens College Union Engineering Society.—Tuesday, January 20th, at 7 p.m. Engineering Society social meeting.

PRICES CURRENT, 14th January, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

„ Australian	91	15	0	„	92	5	0
„ English Ingots	95	5	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues quiet, with limited business. An improvement, however, is noticeable in values of Chili bars, which have advanced about 17s. 6d. per ton since the 9th inst., to-day's quotations being £52 10s. to £53 cash, with small trade. Manufactured is quoted £65 to £66, "strong," with slack demand.

Tin: Values declined during the week, but have again recovered, to-day's prices being about the same as on the 7th inst., the date of our last report.

Lead: Rather lower, with small business.

Spelter is advancing, owing to the small stocks in England, the Baltic ports being closed by ice.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: The new year has not opened very promisingly, there being quite a want of buoyancy about many articles. Carbolic acids continue very dull. Benzoles are less active, but prices are nominally unchanged. Sulphate of ammonia is easier. There is less inquiry for caustic soda; soda ash is steady; bicarbonate of soda drooping. Sulphate of copper is steady on spot, and keeps firm for forward delivery, but there is not much business passing for any position. There is rather more doing in acetates of lime, at slightly easier prices. Acetate of soda is scarce for prompt delivery, shipments from the Continent being interrupted. Prussiate of potash in fair demand. Recovered sulphur scarce

HOME INDUSTRIES.

LONDON, 15th January, 1891.

The Money Market.—After a slight hardening in rates, due to the brief lock-up of large sums in connection with the applications for the new French loan, the money market has moved persistently in the direction of greater ease, and lenders cannot obtain decently remunerative rates for their capital. Continental money rates have also declined, and as the New York Exchange continues to harden, there is nothing to indicate any early change in the position. The stock markets are variable, with an improving tendency, fostered by the cheapness of money and the advance in New York quotations, while the steady rise in silver has told in the same direction. The weak point is the home railway department, the traffic returns being far from reassuring, while the earlier dividend announcements have been decidedly disappointing. The continuance of the labour deadlock in Scotland, and a few stray indications of the beginnings of similar troubles on some of the English lines, help to cloud the horizon in the most important of the home stock markets. The extent to which public attention, both investing and speculative, has been devoted to this department, makes the prospect the more serious. Mining shares have been fairly active, and industrial and miscellaneous securities have been obtaining more than usual favour.

London Institution.—On the 8th inst. a lecture was delivered at the London Institution by Colonel Majendie, C.B., on "Explosives and Some of their Developments and Applications." With reference to the large quantities of explosives used in blasting operations, the lecturer said that recently 3½ tons of blasting gelatine were exploded in the Llanberis quarries, by means of which 214,000 tons of hard gravel were dislodged without any inconvenient projectile effect. In the London and St. Katherine Dock, 2,900lb. of gelatine dynamite were used in the year 1886. In America still larger quantities had been made use of. In 1876, 26 tons were fired in the operations on the Hell Gate Rock, and in 1885, 144 tons of the Sprengler explosive were used at the Flood Rock, which formed an obstruction to New York Harbour. Referring to the progress of the fireworks industry, the lecturer said that nineteen factories were now engaged in the trade, and 689 persons were employed. During last year there had been only four accidents, none of which were fatal. Ten millions of squibs and other fireworks were made each year, each squib requiring fifteen operations and passing through ten pairs of hands.

Annual Report on Copper for the Year 1890.—Messrs. James Lewis & Son in their annual report on copper state that the leading feature of the year 1890 has been the very successful realisation of the large quantity of copper held by the French banks and bankers on account of the official liquidator of the Société des Métaux, the public stocks in England and France being reduced from 93,346 tons to 61,507 tons, and a further quantity, probably amounting to between 10,000 and 15,000 tons, lying in smelters' works and elsewhere, being absorbed by consumers. So well and judiciously were the sales managed that, in despite of them, and in face of the large stock of copper known to exist, the value of good merchantable copper advanced from £50 10s. on the 1st of January to £61 10s. in September, when the last of the Société des Métaux's holding was sold, the final sale being contemporary with the highest price attained during the year, and the markets having since fallen £8 10s. per ton, or to a point within £2 10s. of that at which the year commenced when the public stocks of copper alone were more than 50 per cent. greater than at its close. According to Messrs. Lewis' statistics, there was a decreased import into England and France (allowing for the copper transferred from France to England), and English production in 1890, as compared with 1889, of 1,069 tons, and an increased consumption in, and exports from, England and France of 28,864 tons. English consumption shows an increase of only 411 tons, but the exports from England an increase of 14,120 tons, of which 11,063 tons was of English copper to France, while French consumption has increased to the great extent of 25,396 tons. Whereas the import from the United States into England and France shows a decrease of nearly 10,000 tons, that from Japan shows an increase of 8,000 tons, and from Spain and Portugal of 1,500 tons. From the Cape there is a decrease of 1,500 tons, but from Quebrada an increase of 1,000 tons. With these exceptions there has been but little change in the quantities received from the different producing countries. The consumption of copper during the present year will probably be greater than in 1890, owing to the constantly extending use of electricity, and a probable increased consumption of sulphate of copper.

Tender.—Mr. G. Newnes, M.P., wants a cliff railway or lift constructed at Clifton, Bristol. Those desirous of tendering should send their names as early as possible to Messrs. Marks & Munro, engineers, St. Stephen Chambers, Baldwin Street, Bristol.

Messrs. Woodhouse & Rawson United, Limited.—This firm gave their first annual dinner to the members of their head office staff, at the Guildhall Tavern, E.C., on the 13th inst. Sir Rawson W. Rawson, K.C.M.G., C.B., presided, and there was a large attendance. Mr. F. L. Rawson, managing director, stated that it was the intention of the board at an early date to introduce a system of profit sharing among all their employés. Mr. North, the business manager, stated that a series of lectures had been organised on electrical subjects, for the benefit of the younger members of the staff, and that for attending these no charge will be made.

MANCHESTER, 15th January, 1891.

The Iron Trade.—There is a little more doing in pig iron for prompt delivery, but it is difficult to forecast the immediate future of the trade. There is no doubt that there is a very large amount of work in hand in this district, while the reports from some of the large centres are not so good. It is thought that the price of iron will largely depend upon the future of the coal trade, and in this there does not appear to be any kind of chance of a fall in prices. Any attempt to get a reduction for contracts extending over some months is unsuccessful, and, with the present price of fuel, a reduction in pig iron appears to be impossible. Bar iron is very slow of sale and prices are drooping. It is difficult to assign a reason for this, as all the staple trades of the district in which bar iron is largely used are good, and a large quantity is going in to consumption. The fact remains, however, and no animation prevails in this department.

The Manchester Association of Engineers.—The annual meeting of the above Association was held on the 10th inst., when it was announced that the past year had been a successful one. The President, Mr. John West, C.E., delivered his inaugural address, in which he advocated the establishment in Manchester of a complete scheme for technical education. The scheme should include a large and well-fitted school, which should be the last in a series of continuous stages of education. He urged that the scientific societies of Manchester should have direct representatives on the governing body of the school, and that the teaching should be divided, so as to enable the services of specialists in each department to be secured. He then referred to the taxation of machinery, and expressed regret that the amending Bill referring to the subject had not passed during the last session. Finally the President referred again to the subject of gas *v.* electricity, and said that the right course to pursue was to improve the present antique mode of lighting by an adoption of an improved form of burner. A better light might thus be obtained at considerably less cost than the electric light.

The Late Mr. Alexander Macnab.—The Manchester Ship Canal has suffered a severe loss through the death of Mr. Alexander Macnab, which occurred at Manchester on the 4th inst. Mr. Macnab had taken an important part, under the late Mr. T. A. Walker, in the construction of the Manchester Ship Canal and other important works.

Noxious Vapours.—A memorial has been presented to the President of the Local Government Board praying for an amendment of the Alkali Works Regulation Act, so as to make it more stringent in its operation. After pointing out the deleterious effects on health of the exhalations from these works, the signatories—who are persons engaged in sanitary and social movements—recommend that works, where nuisances arise from the use of chemicals, should be inspected as well as those where they are made, and that the gases to be controlled should be scheduled instead of the works to be inspected. These proposals are far reaching, and require the attention of all concerned.

The Linen and Jute Trades.—The satisfactory manner in which the year's trade opened gave rise to hopes which subsequent events have, unfortunately, tended to lessen considerably. Up to the 12th inst. no consignments of linens had been received for ten days from Scotland, and distributors were beginning to consider the advisability of looking to other sources for the supply of the goods they required. Alarmed at the situation, and fearful of permanently losing a portion of their connection with merchants here, some of the Scotch manufacturers came to Manchester for the purpose of pacifying their *clientèle*. As a result of these visits, urgent telegrams were despatched to Mr. John Walker, the managing director of the North British Railway, at Edinburgh, and a goods train, we are informed, was despatched from Dunfermline, on the 10th inst., with a portion of the goods which had been lying there for some time. This week from 40 to 50 tons of linens were received in Manchester through this action, and we have authority for stating that an effort will be made to effect at least two deliveries per week from the important linen centres in Fifeshire.

The International Okonite Company, Limited.—The directors of the company have announced an interim dividend of 8 per cent. upon the preference shares, and 10 per cent. upon the ordinary shares of the company for the half-year ending on the 31st ult. The dividend is based on the actual earnings of the company since the date of its registration, 24th June, 1890. The new factory at Newton Heath, Manchester, is making rapid progress, and the costly machinery is nearly all ready for delivery.

The Late Mr. Joseph Musgrave.—Mr. Joseph Musgrave, the head of the engineering firm of Messrs. Musgrave & Sons, died on the 12th inst., in the 79th year of his age, at his residence, Western House, Bolton. About the year 1840 his father and himself bought the Globe Foundry, and afterwards the Caledonian Works, from Messrs. Hardman & Openshaw. Their business was gradually extended until they now employ upwards of 1,000 hands, and have constructed some of the largest engineering works in the world, amongst which is the magnificent suspension bridge, over 2,400ft. in length, over the River Dnieper, in South Russia. Mr. Musgrave was one of the earliest promoters of the Bolton Cotton Trade Mutual Fire Insurance Company, Limited, and has from the first been chairman of the directors.

Messrs. John Wild & Company, Limited, Oldham.—At the invitation of the directors, the employés of Messrs. John Wild & Company, Limited, Falcon Iron Works, Oldham, spent an enjoyable evening on the 10th inst. at the Central Conservative Club.

GLASGOW, 15th January, 1891.

The Railway Strike.—The strike still continues to paralyse trade. Representations were made last week by large traders that the suffering should be distributed rather than that the passenger service should be alone considered to the neglect of goods and mineral traffic. This protest resulted in some movement of goods on all the lines, and on the 11th inst. the block at the various depôts was considerably relieved. Still the transport service is in a deplorable state. Many works and shipbuilding yards have not opened yet since the holidays; and in cases where a beginning has been made the employés have been advised that unless coal and material come forward within a few days the works will be closed. Although some of the work is only deferred, yet a large amount of business has already left the district. Orders from abroad are being sent elsewhere, the North of England benefiting largely owing to the paralysis of Scottish industry. Efforts at conciliation continue to be made, but so far without result. Mr. Haldane, Q.C., M.P., made a gallant attempt to settle the difficulty, and influential public men and large traders have done their best to effect a settlement. The railway companies, however, refuse to discuss grievances until after the men return to work. The men are confident, and as they are now, to a large extent, supported by public opinion, refuse to return until some reasonable understanding about hours is arrived at. The trading community is suffering extreme inconvenience. Coals are only obtainable in small lots; cargoes are unprocurable. The shipbuilding yards are working this week, but the steel works are all closed, with the exception of the Clydesdale.

Results of the Strike.—Although the companies have already suffered heavily, both in loss of traffic, in damage to plant through the unskilful work of new employés, and in the depreciation, temporary no doubt, of the capital value of the stock, the greatest sufferers by far are the industrial communities whose operations are practically suspended. The stock of the North British Railway Company has recovered to some extent from the low point reached last week in consequence of the strike and of wild rumours of imminent changes in the management, but it is still about 20 per cent. lower than it was in the first week of October before the threat of a strike was made.

The Edinburgh Railway Schemes.—The three schemes for the increase of railway facilities in Edinburgh were brought before the Edinburgh Town Council on the 12th inst. These schemes are those of the North British Railway, the Caledonian, and the Junction Railway respectively. The areas proposed to be acquired by the companies under the schemes were stated to be 15¼, 14¾, and 15 acres respectively. A number of deputations from various public bodies appeared to state objections to the schemes, and the Town Council resolved to oppose all the railway Bills in Parliament. The summary of the proposals under the schemes was prepared by Mr. Cooper, borough engineer.

Minerals.—The mineral shipments are altogether drawn from Glasgow stock by horse traction, and amount to only a moiety of the amount shipped in the corresponding week of last year. The pig iron market is firm this week, in spite of the falling off in transport facilities, there having been considerable operations on speculative accounts.

Tramways Bill.—The Corporation of Glasgow is promoting a Bill in Parliament to authorise the employment of electrical or other power on the tramways. The lease of the tramways held by the Glasgow Tramway Company expires on 30th June, 1894, and the Corporation bind themselves not to apply the powers asked for until that date unless with the consent of the company. The powers asked for include powers to erect engines and machinery, to construct and maintain subways, tunnels, and cables, and to acquire land and to purchase or lease mechanical power.

(From our own Correspondents.)

LIVERPOOL, 14th January, 1891.

The Liverpool Water Supply.—There is a feeling of great discontent in this city at the restricted supply of water, the hours of supply having been again curtailed. It is stated that the pipe line from the present Rivington supply has become rusty, and although there is ample water in the reservoir it will not supply the demand on the service reservoirs at Prescot. The tunnel under the Mersey is progressing at such an unsatisfactory rate that the direct supply from the Vyrnwy seems as far off as ever, and at a meeting of the Water Committee on the 12th inst. it was unanimously resolved to instruct the engineer to prepare plans for carrying a temporary pipe either across the bed of the Mersey or at a convenient height above it, permission to do so being sought from the Conservators and other interested bodies. The temporary pipe is estimated to cost £5,000.

Digitized by Google

THE LIVERPOOL ENGINEERING SOCIETY.—The annual dinner of this society was held at the Adelphi Hotel this evening, when nearly ninety guests were present. The chair was taken by the President of the Society, Mr. Ferdinand Hudleston, Assoc.M.Inst.C.E., and amongst the invited guests present were the Mayor of Liverpool and other visitors. A most enjoyable evening was spent.

LEEDS, 14TH JANUARY, 1891.

THE IRON AND STEEL TRADES.—The year has opened very quietly, and it is impossible as yet to form a definite opinion as to the prospects of trade generally in the next few months. Prices are unchanged for manufactured iron and steel, and also for pig iron, with the exception of Scotch warrants, which advanced on the 12th inst. A period of inactivity in the building trade, on account of the severe winter, has told somewhat against some of the branches of the iron trade, but after the present thaw things should take a turn for the better. Engineers and some iron-founders are in a good position in regard to work, and we hear of tool makers having orders which will not be completed for another three or more months. It is also reported that orders for torpedoes have lately been placed in Leeds, and if that is the case the contracts will have been entrusted to Messrs. Greenwood & Batley.

THE COAL TRADE.—A question of interest just now, both to coal owners and the representatives of the mining classes, is the letting of locomotive coal contracts. Up to now it has not been possible to obtain accurate information as to these contracts, though it is understood that prices are in advance of what they were on the last occasion.

SHEFFIELD, 14TH JANUARY, 1891.

IRON AND STEEL.—The iron and steel works are again in full operation. There is a slight tendency towards reduced values, and, with the exception of armour plates, the heavy trades are rather quiet. Outside competitors are becoming more numerous each year. Leeds manufacturers are preparing to take up the heavy marine and mill shaft trade, Messrs. Taylors and the Monkbridge Steel Company having each put down a forging press. Although these are on similar lines to the Sheffield tools, and are not nearly so powerful, they will turn out heavy forgings with rapidity. Messrs. Taylors have also put down a splendid heavy lathe (by Greenwood) capable of turning off one ton per hour with four tools, and both these firms make open-hearth steel, in addition to their well-known brands of Yorkshire iron. In steel castings business is decidedly quiet, most of the orders left over from last year having been completed.

COAL AND COKE.—The coal trade continues buoyant, and all collieries are working full time. Some local firms are feeling the effect of increased cost in fuel. One firm, where 500 hands are employed on ordinary general engineers' work, have paid in 1890 over £1,400 more for the same quantity of coal than in 1889. Coke is not in great demand at present, except best qualities for foundry and steel melting purposes. Messrs. Hawksley, Wild, & Co. are extending their boiler and engineering works at Brightside, to enable them better to meet the demand for their specialties.

NORTH STAFFORDSHIRE, 14TH JANUARY, 1891.

THE IRON TRADE.—At the quarterly meeting of the trade, held in Birmingham last week, list prices of finished iron were reduced 10s. per ton. There was no appreciable fall, however, in actual prices, business having been done for some months at figures under list prices. Merchants made use of the official reduction to endeavour to force sellers, but were not generally successful. Pig iron is in better demand, and selling at rather higher prices. There appears to be an expectation on the part of some local iron-masters that there will shortly be an appreciable advance in Scotch warrants.

THE COAL TRADE.—Owing to the want of flints and clay, through the canals being frozen up, several manufactories have been brought to a standstill, and there has consequently been a falling off in the demand for this class of fuel. Colliery proprietors are still unable to keep their customers fully supplied with house coal. Prices have not varied.

BIRMINGHAM, JANUARY 14TH, 1891.

GENERAL TRADE.—The very severe frost in this neighbourhood has effectually stopped all outdoor work for nearly five weeks. Plumbers and gasfitters are in great demand, and makers of gas and lamp stoves have an unusually heavy call for goods. The bedstead trade is rather quiet at the moment, but a good demand is expected. The iron works were making nearly full time right up to Christmas, but since then they have received very few new orders. There is a considerable lull in the iron trade of the district, but it is not expected that prices for finished iron will be materially lower. At the quarterly meeting last week marked bars were reduced 10s. per ton, but the price of fuel continues very high. Engineers generally are very busy, as also are boiler makers. The Royal Small Arms Factory and the Birmingham Small Arms Works are still busily engaged in the manufacture of the much-abused magazine rifle. Chain and cable makers in the Cradley district are not fully employed.

ADMIRALTY CONTRACTS.—The Admiralty has recently asked for tenders for bar iron for the dockyards for the next three years. The contract has been held by the New British Iron Company, Limited, Corngreaves, near Cradley, for the last seven years, and it is hoped that it will remain in the district.

LEICESTER, 14TH JANUARY, 1891.

WOOL SPINNING AND YARN TRADES.—There is no great increase in the amount of business in the local wool market. Users are buying very cautiously, and decline to go beyond their most immediate requirements. As there is an increase in consumption, spinners are more frequently buying, and the tone of business is healthy. Deep-stapled fleeces are making 23s. to 24s. per tod for half hog and ewe lots; superior lots, 24s. 6d. to 25s. 6d. per tod; choice lots, including Shropshires, 26s. to 27s. per tod. The market generally is firmer for fleeces, but skin wools are irregular. Spinners are busier, and a considerable amount of business is on offer, but there is an endeavour being made to obtain better prices. Cashmere and fancy yarns are more in demand. Cotton yarns are flat.

BOOT AND SHOE TRADE.—There is a continual and marked improvement in this industry. Some good orders are now on hand both for home and export. Some heavy contracts have been placed for early spring delivery. The manufacturers' association here have accepted the demand of the workmen's union that all work shall be done in workshops provided by the employers, and have formed a committee to carry the matter into effect. This is an important step, and will considerably affect the industry, as a very large amount of work in some branches has been hitherto done at the homes of the men. Leather merchants are busier, and prices remain very firm.

SWANSEA, 14TH JANUARY, 1891.

THE FLUX QUESTION.—The report of Dr. Heel, of Birmingham, on the samples of flux sent to him for analysis by the Dyffyn men, was received by Mr. Phillips, the General Secretary of the Tinplate Workers' Union. It appears that the liquid flux consists of a strong solution of chloride of zinc, which is present to the extent of 61·1 per cent. The black solid mass also mainly consists of chloride of zinc, but "there is present a considerable quantity of metallic tin and also a little iron." The analyst states that, if the tin is heated much above the melting point, fumes are given off, and if these fumes are inhaled they are irritating and annoying, but that all these difficulties could be obviated by conducting the tinning process under a hood, with a strong draught of air. It is to be hoped that a friendly arrangement will now end the strike.

BARROW-IN-FURNESS, 14TH JANUARY, 1891.

HEMATITE.—An easier tone is noted in the hematite pig iron trade this week, and prospects are not so good as they have been. Bessemer iron is not in such full request as of late, owing to the fact that some of the steel works in West Cumberland have been irregularly employed. Prices are firm at 54s. for hematite warrants net cash and 54s. to 54s. 6d. for Bessemer in mixed numbers net f.o.b. Stocks have again begun to increase—this week's increase being 555 tons. The stocks now held represent 210,923 tons, and makers are considering the advisability of reducing the output. Fifty furnaces are still in blast.

STEEL.—There is steadiness, but not briskness, in the steel trade, and although some mills are stopped because the orders held are largely for forward delivery, there is rather a better prospect, especially in the heavier classes of steel. Rails are being inquired for, with a view to the placing of some heavy contracts, but makers are not very fully sold forward. Prices are steady at £4 17s. per ton for heavy sections, £5 17s. 6d. for light sections, and £7 for colliery rails. In steel shipbuilding material there is no improvement to note, but on local account a fuller demand is expected. Prices are steady at £6 7s. 6d. for plates, £5 12s. 6d. for angles, and £7 2s. 6d. for boiler plates. Other branches of the steel trade are unchanged.

IRON ORE.—Much steadiness is noted in the iron ore trade, and business is being done at 11s. 6d. to 12s. per ton net at mines. The latter are better employed than they have been for some time past.

MIDDLESBROUGH, 14TH JANUARY, 1891.

PIG IRON.—Since last report the tone of the market has been somewhat more favourable, and prices have slightly improved. On the 12th inst. No. 3 G.M.B. was quoted at 43s. 3d., but yesterday it fell to 43s. There is an impression, however, that prices have reached their lowest point. It is expected that with milder weather there will be an improved trade, as consumers must now be short of supplies. It is thought, too, that Scotland will take more when the Scotch ironmasters have depleted their stocks. Connal's stores have 33,000 tons more than when the strike began. On the 12th inst. the stock amounted to 119,881 tons.

WAGES.—The mine-owners have had a protracted meeting with the miners' representatives, and claimed from them a reduction of 12½ per cent. The high price of coke and the low price of iron are seriously affecting the trade, and unless relief is obtained disaster will ensue to all concerned.

MANUFACTURED IRON AND STEEL.—The outlook for the new year is by no means bright, and the demand for steel is very quiet. Iron ship plates are £5 15s.; ship angles, £5 10s.; and common bars, £5 15s.; steel ship plates, £6 2s. 6d.; ship angles, £6; engineering angles, £6 5s.; and rails (heavy section), £4 17s. 6d. per ton, all f.o.t. at works less the usual discount.

SHIPMENTS OF PIG IRON.—The shipments up to the end of last week amounted to only 12,525 tons. Up to the 12th inst. the shipments for the current month amounted to 12,525 tons, against 32,031 tons to similar date in December and 16,860 tons to the 12th of January, 1890.

THE TEES COMMISSION FINANCES.—The revenue of the financial year (which ended on the 31st October) has recently been announced as £69,069, as against £70,062 in the previous year, a falling off accounted for by the decrease in the shipments of pig iron during the spring, when the prices of pig iron were high. The total indebtedness of the Commission now stands at £838,125 14s. The Commission has about 1,000 acres of reclaimed land, under which it is believed that salt deposits lie. Tenders for working those salt deposits have just been advertised for.

BOILER EXPLOSIONS AT WEST HARTLEPOOL.—About 10 o'clock p.m. on the 6th inst. two boilers exploded at the Seaton Carew Iron Works, West Hartlepool, causing considerable damage to the works and destroying the offices of the company. One man was scalded, and another was seriously injured in the head. Travelling on the North-Eastern Railway was interrupted for a short time owing to portions of the boilers disturbing the permanent way. The boilers were 60ft. in length, 4ft. in diameter, made of ⅜in. plates, heated by furnace gases. They both appear to have ripped round at the circular seam about the middle of their length. The steam pressure per gauge is reported to have been about 37lb. at the time of the explosion, although the safety valves are said to have been weighted to 60lb. per square inch. Both boilers are, we understand, insured in the Scottish Boiler Insurance and Engine Inspection Company.

NEWCASTLE, 14TH JANUARY, 1891.

THE IRON TRADE.—Within the past few days a more hopeful feeling has been manifested in the finished iron trade, and, though prices have not altered, offers from consumers to negotiate for future supplies have become more numerous. Works are generally busier than they were for some time before the close of last year, but this improvement is largely to be accounted for by the necessity of making up for time lost by the observance of the Christmas holidays. In the forges business has fallen off, owing, no doubt, to the dearth of new orders in shipbuilding, but iron foundries are for the most part well employed. Rivet works are also less active, and though in the chain and anchor trade unfinished orders are still keeping the works fully engaged, it seems likely that when these orders are completed an interval of slackness will occur.

THE COAL TRADE.—Since last week no change of importance has occurred in connection with the local coal trade, but it is stated that the employers contemplate reducing the miners' wages, and it is thought probable that opposition will be experienced if their intention is carried out. The shipments of coal and coke at Tyne Dock during the week ending 10th January amounted to 96,493 tons, being a decrease as compared with the shipments in the corresponding week last year of 5,424 tons.

GLASS WORKS AND POTTERIES.—In these establishments business is less brisk than during the closing weeks of last year, the falling off being, no doubt, attributable to the fact that customers are not now so urgently in need of supplies of goods. In the bottle works, however, the production is fully maintained, the demand being quite equal to the supply.

ELECTRIC LIGHTING.—Messrs. J. H. Holmes & Co. continue to have plenty of work in all their departments, the number of steamship installations arranged for, to be fitted by the firm during the next few months being no less than thirty. Some of these are of special importance, one being for a foreign steamer of the very largest class, which is now being built on the Tyne. The firm completed fifty steamship installations in 1890.

DUNDEE, 14TH JANUARY, 1891.

JUTE AND FLAX TRADES.—In consequence of the railway strike some factories are in danger of running short of coal, and the difficulty in distributing goods is causing much inconvenience. Where possible, consignments are being sent and received by sea, but business generally tends to become disorganised. Jute is selling moderately well. The fluctuation in the Exchange makes prices somewhat unstable. This week the rupee price of first marks is R.20 8an. per bale of 400lb. In jute yarns there is not much activity, but prices are well maintained. Cable advices from Calcutta report Australian cornsacks dearer. Hessians, 40in. 10½oz., are quoted at 4⅞c. per yard in New York; light weights, at from 4¼c. to $4\frac{9}{16}$c. per yard. The prices at present obtainable in the American market are up to the average of the last three months. In the earlier half of last year the ruling price was about 5⅜c.

IMPROVED WATER-TUBE BOILER FOR TORPEDO BOATS.

CONSTRUCTED BY MESSRS. YARROW & CO., ENGINEERS, POPLAR.

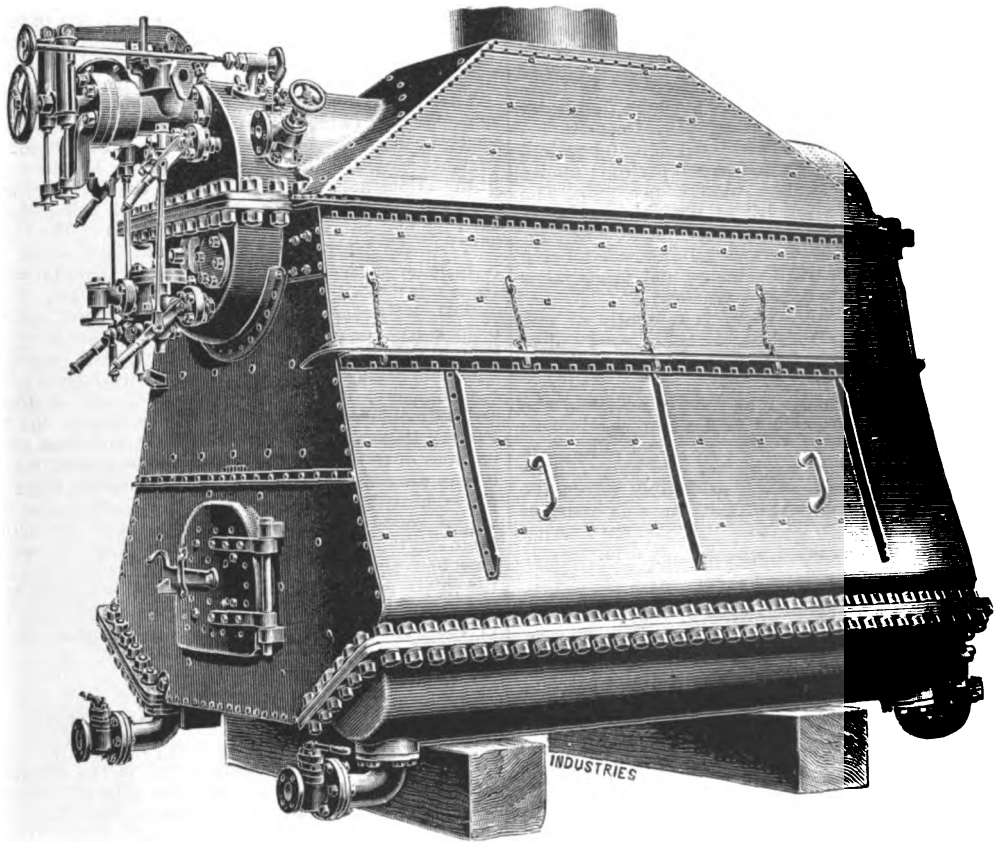

FIG. 1.—GENERAL VIEW.

IMPROVED WATER-TUBE BOILER FOR TORPEDO BOATS.

GENERALLY speaking the locomotive type of boiler is employed for torpedo boats in connection with forced draught, but although, under ordinary conditions, and when well designed and constructed, such boilers give little trouble, yet, when worked at their maximum power for considerable periods, numerous failures have occurred,

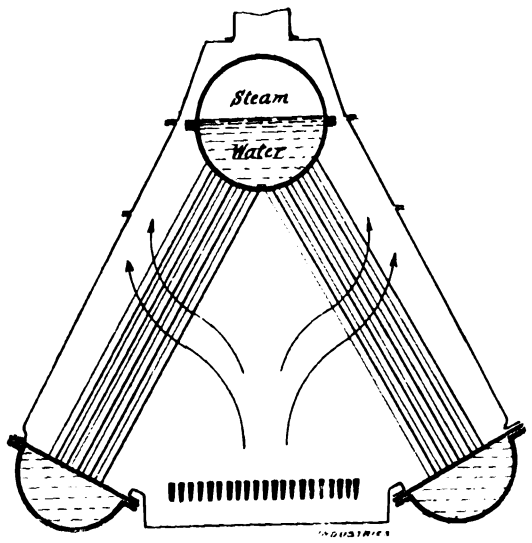

FIG. 2.—TRANSVERSE SECTION.

due mainly to leaking tubes. In order to avoid such mishaps, and in view of the probable further increase in boiler pressures, Messrs. Yarrow & Co., of Poplar, have constructed a new form of tubulous or water-tube boiler. One of these boilers, fitted to a second-class torpedo boat built for the Argentine Republic, we recently had an opportunity of inspecting, through the courtesy of Messrs. Yarrow & Co. The boat has a length of 60ft. and 9ft. 3in. beam, the displacement being, when fully loaded, about 15 tons. The engines are of the triple-expansion type, with surface condensers, and are capable of developing 250 horse-power.

The general construction of the new boiler will be clear from Figs. 1 and 2. Two parallel longitudinal chambers, the cross-section of each having the form of a sector of a circle, are united with a third—of cylindrical shape—by a great number of steel tubes. The section thus resembles an inverted V with the cylindrical chamber at the apex, the tubes sloping downwards at an angle of about 30 degrees. The two lower chambers form water-pockets, and the water extends up to about the middle of the top chamber, the remaining space of the latter being filled with steam. The flat surfaces of the water-pockets form the tube plates at one end of each series of tubes, the other ends being secured in the lower half of the cylindrical upper chamber. Each of the three chambers is about 6ft. long, and the upper cylinder has a diameter of about 20in.; each is made in two parts, with longitudinal flange joints. By removing the lower (circular) portions of the water-pockets and the upper part of the top cylinder all the tubes are rendered accessible for cleaning or renewal. There is no direct connection between the lower chambers, and the whole system has complete freedom for expansion. The grate occupies the space between the water-pockets, and the fire gases ascend between the tubes on either side, as indicated in the sketch, and over the top cylinder to the funnel. With the exception of the lower portion of the water-pockets, the whole is enclosed in a double wrought-iron casing filled with asbestos. All the tubes and chambers are of steel, and galvanised within and without. The feed-water is introduced from the front into the top cylinder near the middle of its length.

The circulation takes place upwards through the hotter inner tubes—next the furnace—and downwards through the outer tubes. Contrary to what might have been expected from the design, it is stated that no priming takes place.

The boiler in question is not an experimental one, as Messrs. Yarrow have built several of the same type, which have been at work for some years. No trouble has been experienced from leaking tube joints, and it may here be noticed that there is an essential difference between the conditions obtaining in an ordinary locomotive boiler, where the tubes are filled with the fire gases and are subject to external pressure, and those existing in Messrs. Yarrow's boiler, in which the water fills the tubes. As compared with a locomotive boiler suited for the same work, it is stated that the new generator is about 10 per cent. lighter, including coal and water. The cost is about the same in both cases.

The average speed of torpedo boats of the dimensions previously stated, and of the same type as that shown us, when fitted with locomotive boilers, is 17 knots; the boat with the new boiler runs at 18 knots under exactly similar conditions of trial. This increase of speed is ascribed partly to the smaller weight of the boiler and partly to its greater steaming capacity. Appended are the results of the official trial, which took place at Long Reach, on the Admiralty measured mile, on December 23rd, 1890:—

LOAD ON BOARD, TWO TONS.

Steam. Lbs. per sq. in.	Vac'm. Inches.	Air Pressure.	Revns. per Min.	Time. h. m.	Speed. Knots.	1st Means.	2nd Means.
170	23	2·7	570	3 3	19·672	17·765	
170	23	3·2	577	3 47	15·859		
170	22·7	3·5	568	3 1	19·890	17·909	18·021*
171	22·5	3·3	680	3 46	15·929	18·113	18·098*
172	22·7	3·2	597	2 57	20·338	18·063	18·121*
172	23	3·6	578	3 48	15·789	18·180	18·215*
174	22·5	3·1	582	2 55	20·571	18·250	
173	23	3·4	583	2 56	15·929		
172	22·7	3·35	578				

* Admiralty means, 18·113.

From our description it will be seen that the design of this boiler is of an eminently practical character. The fact that all the tubes are straight and of nearly the same length is a strong point in its favour, especially at foreign stations, as it is not necessary to carry a reserve of curved tubes bent to various templates, and the whole apparatus is almost as easily accessible for cleaning and repairs as a locomotive boiler.

THE BOARD OF TRADE RETURNS.

THE last Board of Trade returns issued cover the month of December, and also the whole trade of the past year. The value of the exports in December was £21,384,270, as compared with £21,001,670 in December, 1889, an increase of £382,600, or 1·8 per cent. In coming to the items, metals show a falling off. The value of unwrought and wrought copper was £389,223, as compared with £413,382, a decrease of 8 per cent., and the value of unwrought and wrought iron was £2,268,958, as compared with £2,508,030, a decrease of 9½ per cent. The value of hardware and cutlery fell to £224,344 from £242,671, a decrease of over 7½ per cent., but, on the other hand, machinery and millwork rose slightly, the figures for last month being £1,349,037, as compared with £1,325,675 in December, 1889. Coal, coke, and fuel have advanced considerably, the value being £1,535,230, as compared with £1,245,104, an increase of over 23 per cent. In the textile trades, cotton yarn is £1,030,133, as compared with £901,001, an increase of over 14 per cent.; cotton piece goods, £4,920,402, as compared with £4,123,080, an increase of over 19 per cent.; jute yarn, £32,398, as compared with £36,982, a decrease of nearly 12½ per cent.; jute piece goods, £229,584, as compared with £231,085, a slight decrease; linen yarn, £68,577, as compared with £77,124, a decrease of over 11 per cent.; linen piece goods to £334,906, as compared with £398,751, a decrease of 16 per cent.; silk manufactures to £151,894, as compared with £191,137, a decrease of 20½ per cent.; woollen and worsted yarn to £293,286, as compared with £371,766, a decrease of over 21 per cent.; woollen tissues to £484,008, as compared with £558,498, a decrease of over 13 per cent.; and worsted tissues to £689,986, as compared with £921,586, a decrease of over 25 per cent. In chemicals, alkali was £170,850, as compared with £123,476, an increase of nearly 38½ per cent.; bleaching materials, £39,085, as compared with £47,922, a decrease of nearly 18½ per cent.; and manures, £181,155, as compared with £191,414, a decrease of over 5 per cent.

The value of the goods imported during the month amounted to £39,434,448, as compared with £38,297,208 in December, 1889, being an increase of £1,137,240, or about 3 per cent. Raw materials for textile industries were £9,900,104, as compared with £10,232,829, a decrease of 3⅓ per cent. Metals were £2,220,215, as compared with £1,977,357, an increase of over 12 per cent.; chemicals, dyestuffs, &c., £771,395, as compared with £628,155, an increase of nearly 23 per cent.; and oils, £655,451, as compared with £655,099, a slight increase.

The exports for the year ended 31st December amounted to £263,542,500, as compared with £248,935,195 in 1889, being an increase of £14,607,305. The imports for the year amounted to £420,885,695, as compared with £427,595,442 in 1889, being a decrease of £6,709,747.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 389, Strand, London, W.C.*

FRIDAY, 16TH JANUARY, 1891.

PATENT FEES AND THEIR EFFECT UPON INVENTION.

WHEN the Patent Act of 1883 came into force the public generally, and inventors in particular, expected, in a vague sort of way, that great benefits would follow. There is no doubt that the alterations then made in the law have, on the whole, been beneficial, but the numerous complaints that come to the front every now and then show that there is still considerable discontent with regard to the working of many of the details of the existing patent laws. The most important question is, perhaps, that of fees—that is, as to what amounts they should be fixed at, and to what purpose they should be applied.

There is considerable misunderstanding regarding the nature of the property embodied in patents and copyrights. Many people seem to think it is perfectly obvious that an invention being the product of a man's brain, he, therefore, has an absolute right of property in it. This is, of course, an entire misunderstanding of the case. Property is really of the nature of a bargain. If a person in this country owns a house, or plate, or an estate, it is held under an unexpressed contract with the State, or that organised system of society of which he is a member. The State finds it is best for all that each member should retain what he acquires and should not be robbed of it; so that the general understanding is that each person retains his own property and abstains from taking that belonging to others. The reality of this general understanding or bargain is easily shown in the case of patent and copyright properties, for both came into existence as bargains, whereas the origin and growth of private general property is more difficult to trace. As regards patents the arrangement with an inventor is briefly this. The State says, in effect: "The public see the advantage of improvements in all sorts of manufactures, but, as it is not the business of any particular person to make them, they would not be made at all unless some special inducements were offered. It is better for the public good to have the deferred use of improvements than not to have them at all. An inventor is, therefore, offered a monopoly for fourteen years of his invention if he introduces a new manufacture, and shows the public how to work it." Exactly the same idea underlies copyright law. It is considered a good thing to have books, but, if nothing were done to encourage authors and publishers, books might not be forthcoming. With regard to international patents, we maintain that if a monopoly of fourteen years in one country is a fair remuneration for a given invention, it may be contrary to the public interest to give this invention a monopoly in several other countries for a similar period. From this point of view the whole system of international patent law is, in our opinion, on an unsatisfactory basis. A patentee would probably submit that he has a right to foreign as well as English patent rights, inasmuch as he has paid large fees for his privilege. But this would be a complete misunderstanding of the nature of fees. An inventor is not given the privilege embodied in a patent because he has paid certain fees, but in return for his trouble and risk of monetary loss in bringing out his invention. The fees are merely incidental. If the fees were really the purchase money of the monopoly there would be no need for a would-be monopolist to invent anything, as he might at once buy a monopoly of anything he might name, without inventing.

In most kinds of copyright, it is easy to know exactly in what the monopoly consists, though in cases of photographs of celebrated persons curious points have arisen. With regard to an invention, however, a document or documents must be lodged in some specified place which state clearly and exactly the extent of the monopoly granted. This necessarily entails some little expense. If copies are printed, as indeed they must be, the printing is partly, if not wholly, paid for by purchasers, but in the case of many specifications, which have a small sale, there will be some loss. This small loss, and the expense of registering patents and performing the other necessary work of the Patent Office, should be quite trifling; and an inventor should be able to secure protection for his invention for a very modest fee. The reason for the high fees now charged is not difficult to explain.

A system of government is an admitted necessity, and in order that the expenses of government may be met the public must submit to taxation. Every form of taxation is more or less distasteful to the public, and yet taxation is necessary in order to supply the government with revenue. An important problem which the statesman has to solve is how to get the necessary revenue with the least apparent pressure on the public. Generally speaking the best method is to levy certain taxes that appear to fall heavily upon the wealthy, and not to affect the poorer classes. So little is generally understood about the actual incidence of taxation that this policy is generally the most effective. There are, however, several still more effective methods of raising revenue, such as the working of a department like the Post Office at a profit. The head of such a department is free to say to the public: "Look how well I manage your letter-carrying generally; not only do I carry your letters for you for the ridiculously small sum of one penny, but I make a considerable profit out of the business, and thus lessen your taxes." Some persons really think that a benefit has thus been conferred, and are much pleased. The Patent Office, however, gives the statesman a still better chance of ingratiating himself with the public. In the case of the Post Office the public has to pay its penny, and has, moreover, to put up with many small inconveniences, which are sometimes a little exasperating. The Patent Office costs the general public nothing. The statesman is, therefore, able to point out the advantages to industry and invention of our patent laws, and dwell on the great benefits that accrue from cheap protection to inventors. He, however, arranges a scale of fees that shall not be so high as to prevent applications for patent rights, nor so low as to leave little or no surplus after paying the necessary expenses of the office. He, in fact, fixes the scale of charges so as to obtain the greatest possible revenue. This policy really throws an abnormally heavy tax upon inventors—a tax which has no counterpart in the case of copyright, or in that of any other monopoly. The average patentee is so sanguine about the merits of his own invention, and of its chances of success, that he unwittingly bears an undue load of taxation—in other words, he

Digitized by Google

is fined by the State because he is an inventor, and in some cases a great public benefactor.

We thus see how both inventors and the progress of industry are hampered and taxed. That a public department like the Patent Office should be made a source of revenue is deplorable. We hope to consider the question of the details of patent fees at some future time. We only wish to point out now the shameless way in which inventors are taxed on the one hand, and the progress of industry hindered and hampered on the other, for the mere object of raising a small amount of public revenue.

THE RECENT MOVEMENT OF TRADE AT OUR PRINCIPAL PORTS.

One of the principal matters of local interest at the chief ports of the United Kingdom is the question of how far the trade and commerce of the individual port, as represented by the entrances and clearances of shipping, or by the value of the imports and exports, is increasing or diminishing by comparison with the business done at other ports at which the same character of business is carried on. As is very well known, there is a great deal of rivalry between the various ports in reference to their facilities and resources, and most of them have expended large sums of money with a view to providing the means of attracting shipping business, and earning a larger amount of revenue therefrom at the expense of other ports. The amount of capital sunk in this endeavour in the various shipping centres of Great Britain is not very readily ascertainable, but it must be enormous. Liverpool alone has expended nearly thirty millions sterling in making the Mersey the most convenient harbour in that region, and yet, as is generally admitted, has not been altogether successful in that endeavour. In London, again, the amount of money spent upon docks, wet and dry, upon warehouse accommodation, upon loading and unloading facilities, upon the channel of the Thames, upon lights and beacons, and upon other means to the same end, must have been very large, and the capital of the dock companies alone runs into a good many millions; and so with many other ports throughout the Kingdom as a whole. There is hardly a harbour, however obscure, that has not had its quay walls extended, its area deepened, its facilities improved, and its general character, so to speak, rehabilitated, with a view to the acquisition of some share of the enormous trade that is carried on between the United Kingdom and the rest of the world.

The most important ports of import in the United Kingdom are, of course, London and Liverpool. These ports have long been engaged in a very close race for the championship of the world, as regards the extent of their shipping trade and the value of their imports and exports. The enormous population of London naturally makes the Thames a point towards which imports largely gravitate for the purposes of distribution. This is especially true of breadstuffs, and of articles subject to Customs' duties, such as tea, coffee, and wines. Liverpool, on the other hand, is the shipping centre for almost as large, if not a larger population, than even that of greater London, the promoters of the Manchester Ship Canal having calculated that there was a population of over seven millions tributary to Liverpool. The latter port, again, has this in its favour, as against London, that it is the shipping centre of an enormous manufacturing population, which draws upon the outside world for supplies of raw materials, such as raw cotton, raw wool, pyrites for the alkali manufacture, unhewn timber, caoutchouc, leather, and other imported materials that are worked up in subsequent processes of manufacture. To this extent, then, the import business done at these two several ports is distinct and characteristic. The value of the imports at each of the principal English ports in 1880 and 1889 is appended:—

Value of Imports at the Principal Ports of England and Wales in 1880 *and* 1889.

	1880. £1=1,000.		1889. £1=1,000.		Increase (+) or Decrease (−) in 1889. £1=1,000.
London	141,443	...	144,711	...	+ 3,268
Liverpool	107,460	...	111,152	...	+ 3,692
Southampton	9,205	...	8,964	...	− 241
Newcastle	6,602	...	7,618	...	+ 1,016
Hull	20,163	...	26,288	...	+ 6,125
Bristol	8,481	...	8,115	...	− 366
Cardiff	2,338	...	2,518	...	+ 170
Barrow	791	...	635	...	− 156
Grimsby	3,906	...	5,774	...	+ 1,868
Goole	3,836	...	4,803	...	+ 967
Total	304,225	...	321,578	...	+ 17,343

It will be observed that the increase that has taken place in the interval has not been much different as between London and Liverpool, and that Hull, Grimsby, and Goole are the only other ports that show a notable advance, these making up a total increase exceeding that shown by London and Liverpool, from which the inference is obvious that the Yorkshire ports are becoming more largely the distributing centres for the imported breadstuffs and other commodities required in the manufacturing towns of that county. The exports from the same ports for the same two years have been as under:—

Value of the Exports of the Produce of the United Kingdom at the Principal Ports, 1880 *and* 1889.

	1880. £1=1,000.		1889. £1=1,000.		Increase (+) or Decrease (−) in 1889. £1=1,000.
London	52,600	...	48,251	...	− 4,349
Liverpool	84,029	...	102,513	...	+ 18,484
Southampton	9,306	...	8,341	...	− 965
Newcastle	4,528	...	4,560	...	+ 32
Hull	18,572	...	16,768	...	− 1,804
Bristol	1,763	...	1,148	...	− 615
Cardiff	4,161	...	6,533	...	+ 2,372
Barrow	1,201	...	401	...	− 800
Grimsby	7,236	...	7,429	...	+ 256
Goole	3,093	...	5,556	...	+ 2,663
Total	186,489		201,763		+ 15,274

Here it will be observed that Liverpool has very largely outstripped any other port on the list, and has left London far behind, the difference in imports and exports together amounting to about 21 millions in favour of the great Lancashire port, whereas in 1880 the difference was some two millions in favour of London. Liverpool is now far ahead of every port in the world as regards the value of its import and export trade. It has outrun London, not so much because of its superior facilities, or lower dues, or better access, or nearness to other countries, as because of its geographical situation in relation to the great manufacturing centres of Lancashire and Cheshire. It is probable, also, that in the year 1889 some exporters, who would otherwise have shipped from the Thames, transferred their shipments to Liverpool, or to some other port, in order to be rid of the uncertainty and difficulty created by the dock strikes.

There is another important point in reference to which the superiority of Liverpool stands out with marked prominence. It will be observed that the import and export trade of that port almost balance each other, there being a difference of less than nine millions between them. In the case of London, however, there is a difference of some 96 millions as between exports and imports, and the difference, which amounted to 89 millions in 1880, clearly tends to increase. This means that the vessels that enter the Thames have nothing like the same good chances of outward cargoes as the Liverpool-bound ships, and that their homeward freights must consequently be higher. As regards many ships engaged in the transportation of such comparatively costly commodities as tea, coffee, and spices, there is usually a sufficient margin in the homeward freight to allow of a large provision in the way of outward ballast.

The next tabular statement shows how the shipping business of each part of the United Kingdom compares over the last five years as regards the value of the imports received into the ports generally.

Value of the Total Imports received at Ports in England and Wales, Scotland, and Ireland, 1885 *and* 1889.

	England and Wales. £1=1,000.		Scotland. £1=1,000.		Ireland. £1=1,000.		Total. £1=1,000.
1885	330,755	...	32,170	...	8,982	...	370,968
1886	315,117	...	27,919	...	6,802	...	349,863
1887	324,457	...	29,771	...	7,973	...	362,227
1888	349,147	...	31,221	...	7,232	...	387,635
1889	382,508	...	36,771	...	8,319	...	427,637

The same movement has been apparent in exports from the three divisions of the United Kingdom, England and Wales having largely improved their position during the last five years, while Scotland and Ireland, although both showing decidedly better results, have each advanced to a much less extent. More than one-half of the exports of Scotland are shipped from Glasgow, which is a large manufacturing centre, and is annually increasing the value of the machinery, &c., that it sends abroad. Of course, were the tonnage of the ships built on the Clyde to be treated as an export, the relative importance of Scotland would stand much more prominently forward:—

Value of the Total Exports of the United Kingdom Shipped from England, Ireland, and Scotland, respectively, at Different Dates.

	England and Wales. £1=1,000.		Scotland. £1=1,000.		Ireland. £1=1,000.		Total. £1=1,000.
1885	193,412	...	18,881	...	750	...	213,944
1886	193,368	...	18,248	...	816	...	212,132
1887	201,760	...	18,849	...	805	...	221,414
1888	212,150	...	20,821	...	871	...	233,842
1889	224,924	...	22,310	...	813	...	248,048

It will be understood that in this analysis we have only dealt with the principal ports and with general results. There are many smaller ports in the United Kingdom that have their own special trades, such as Stockton, Middlesbrough, and the Hartlepools, that do a large business in the exportation of iron; Blyth, Seaham, and other North country ports, that do a large business in the exportation of coal, and so on. But these ports do not, as a rule, take a large, nor a greatly varying part in the general import and export business of the country, being excluded therefrom, except to a very limited extent, by their geographical position, and by the usually insufficient character of their facilities. Newport and Swansea, in Wales, are entitled to be treated as exceptions to this rule.

INDUSTRIAL WILLS OF 1890.

The following are the more important of the industrial wills proved in 1890:—

Coal and Iron.—C. R. M. Talbot, of Margam Abbey, M.P., £1,388,617; Wm. Hargreaves, Soho Ironworks, Bolton, £586,455; Andrew Knowles, of A. Knowles & Sons, coal owners, £316,653; David Davies, Welsh coal owner, £404,000; James Nasmyth, inventor of steam hammer, £243,845; Joseph Mills, Kingswinford, Staffordshire, £140,842; Handel Cossham, M.P., coal owner, £59,127: and Daniel Adamson, Didsbury, engineering works, £41,489.

Cotton, Linen, &c.—Samuel Fielden, Todmorden, cotton spinner, £1,170,113; James Ormrod, Bolton, cotton spinner, £432,000; Henry Maden, Bacup, cotton spinner, £327,588; John Grubb Richardson, Bessbrook Spinning Company, Ireland, £226,477; Fred. Wm. Grafton, calico printer, Accrington, £215,951; James Hargreaves, Heywood, cotton spinner, £282,706; Sir Peter Coats. thread spinner, Paisley, £123,457; John Fish, Southport, cotton spinner, £99,447; and Sir John Preston, linen manufacturer, Belfast, £94,000.

Railways and Shipping.—T. A. Walker, contractor, £551,694; Arthur O. Wilkinson, Lloyd's, £100,545; Sir George Burns, Bart., Cunard Company, £91,357; and Ed. Fletcher, chief engineer, North-Eastern Railway, £75,178.

Miscellaneous Manufacturers.—Christian Allhusen, Newcastle-on-Tyne, chemicals, £1,128,852; John Noble, varnish manufacturer, £929,044; Stephen Christy, hat manufacturer, Stockport and London, £283,254; James D. Doulton, art pottery, Lambeth, £115,544; Hugh M. R. Ewing, Turkey red dyer, £108,000; George B. Kent, household implements, £61,500.

Merchants.—Bernard Hall, Liverpool, £533,552; Sir T. Edwardes Moss, Bart., West Indian merchant, £494,844; Robert Needham Phillips (of Welcombe, Warwickshire), J. A. Phillips & Co., Manchester, £428,087; Joshua M. Heap, merchant and sugar refiner, Liverpool, £330,472; George B. Blair, Balfour Bros., Liverpool, £219,129; Daniel H. Rücker, colonial broker, London, £169,895; Philip Falk, colonial merchant, London, £159,279; W. E. Baxter, of Kincaldrum, Dundee, merchant, £128,903; John Hartley Hind, J. H. Hind & Co., hemp merchant, Liverpool; Lord Addington, Russian merchant, £112,000; Edward W. Bell, merchant, Bradford, £102,000; and Henry Cox, merchant, Liverpool, £100,000.

Bankers.—Junius S. Morgan, J. S. Morgan & Co., London and New York, £2,022,054; Robert C. L. Bevan, Barclay, Bevan, & Co., £951,886; Henry Oxley, Leeds, £420,286; Edward Bolitho, £383,601; Robert Williams, Williams, Deacon, & Co., £214,147; Philip Playdell Bouverie, Ransom, Bouverie, & Co., £164,438; Edwin Henty, Worthing, £143,962; Sir Charles W. Sikes, Huddersfield Banking Company, £141,414; Thomas Lloyd, Warwick, Lloyd's Bank, £129,000; William G. Coles, Stuckley's Bank, £119,888; and Right Hon. E. P. Bouverie, Ransom, Bouverie, & Co., £91,627. We should add the name of Miss Anne Raphael, Stockwell Hall, Essex, who left £236,000, largely bequeathed to her by her brother, Edward Raphael, foreign banker in London, who died in 1888.

Stock Exchange.—Sir James Mackenzie, Bart., of Glenmuick, £659,022; Wm. Morris, of Morris & Pickle, London stock dealers, £356,000; Isaac Brathwaite, of Foster & Brathwaite, London stock brokers, £289,059; Fred. Banbury, London stock broker, £221,000; and Wm. Hy. Barry, London stock broker, £119,000. Mr. Jacob J. Astor, the American millionaire, left £290,809 in this country, and Mrs. McCalmont, Eaton Square, who left £132,873, owed her wealth to the great house of McCalmont & Co., whose head, Mr. Hugh McCalmont, died in 1887, leaving more than three millions sterling.

Printers and Publishers.—Edward Lloyd, owner of *Daily Chronicle* and *Lloyd's News*, £563,022; Sir Edward Baines, owner of *Leeds Mercury*, £165,818; George Routledge, publisher, £94,000; Ch. Ed. Mudie, London

Digitized by Google

library, £59,347; and Robert Farran, of Griffith, Farran, Okeden, & Welsh, £30,000.

Brewers, &c.—Charles Goding, Lion Brewery, £409,625; Charles Florance Young, Wandsworth Brewery, £349,915; Pickering Phipps, Northampton brewer, £263,311; Hugh Tennant, Wellpark Brewery, Glasgow, £230,226; Sir Edward P. Cowan, Irish distiller, £213,000; Mrs. Charrington, Anchor Brewery, Whitechapel, £192,204; Charles Dobson, wine shipper, London and Bordeaux, £169,940; Christopher Hall, wine merchant, Whitechapel, £127,000; James Jameson, Dublin Distillery Company, £85,588; Arthur L. Charrington, Charrington & Co., Burton-on-Trent, £75,320; and Wm. Allen Block, London wine merchant, £82,000.

QUICK STEAMING BETWEEN QUEENSTOWN AND LIVERPOOL.

On Saturday last the Cunard steamer "Umbria" made a remarkable passage between Queenstown and Liverpool. After a smart passage of 6 days 6 hours and 59 minutes across the Atlantic against easterly winds, she left Queenstown on Saturday at 2.5 a.m., in order "to catch the tide" at Liverpool. In order to avoid waiting outside the bar, advantage was taken of the clear weather to steam the "Umbria" at her best, and not only was the bar successfully crossed, but with time to spare, the run from Queenstown occupying only 10 hours and 40 minutes. It was performed at an average speed of nearly 22 knots per hour. It is supposed that this speed has not been exceeded in any passenger vessel afloat.

COAL, IRON AND COGNATE INDUSTRIES.

The Board of Trade returns for December and for the twelve months then ended have now been published. The declared value of the exports for the month is £21,384,270, and for the twelve months £263,542,500, being an increase of £382,600 and £14,607,305 respectively, as compared with the corresponding periods of the previous year. The declared value of the imports for the month is £39,434,448, and for the twelve months £420,885,695, being an increase of £1,137,240, and a decrease of £6,709,747 respectively, as compared with the corresponding periods of 1889. The total quantity of iron and steel exported last month was 263,559 tons, valued at £2,268,958, being a decrease of 51,445 tons in quantity, and £239,072 in value, as compared with the corresponding period of last year; for the twelve months the exports amounted to 4,001,579 tons, valued at £31,582,172, being a decrease of 184,603 in quantity and an increase of £2,440,043 in value. Exports of coal show no signs of relapse, and an increase in their value to the amount of £4,237,999 for twelve months is, indeed, a remarkable proof of the vitality of this branch of the coal trade during 1890.

We append our usual tabular statement:—

	Month of December.		Twelve Months.	
	1890.	1889.	1890.	1889.
Pig and puddled	£168,696	£258,777	£3,502,050	£2,988,324
Bar, angle, &c.....	172,841	127,857	1,655,081	1,624,576
Railroad.....	332,036	511,856	5,983,547	5,330,858
Cast and wrought ...	448,743	491,527	5,974,467	5,431,422
Hoops, sheets, &c. ...	329,079	336,126	3,844,134	4,133,667
Unwrought steel.....	145,582	161,588	1,904,075	1,699,010
Unwrought copper ...	263,600	219,663	2,634,803	1,536,917
Coals, &c.	1,535,230	1,245,104	19,019,989	14,781,990

A retrospect of the twelve months shows that the foreign and home trades have been subject to similar influences. In the iron trade the year opened with considerable excitement, prices in all branches having reached a point in excess of any experienced since 1875; and opinions were freely expressed by many shrewd members of the trade that a still higher level was to be anticipated. The January quarterly meetings afforded a reflex of this opinion, and much legitimate and speculative business was transacted. Taking Scotch pig iron warrants as affording a fair barometrical reading of the general industry, these were sold at 65s. per ton in the early days of last year. Directly afterwards, however, a downward tendency became apparent, and owing partly to speculative necessity, and partly, no doubt, to a diminution in immediate consumption, and to a perceptible relapse in iron-consuming industries, more particularly in that of shipbuilding, the fall assumed a continuous rapidity unprecedented in the annals of the trade. Before the close of the first half of the year warrants had fallen fully £1 per ton, and, although during the last six months some important fluctuations occurred, the year closed with warrants selling at 46s. In respect of the coal trade, for collieries near the sea board producing a good steam coal there has been a large demand throughout the year. The railway companies have had to pay much higher prices for their fuel supplies. In the house coal trade demand continued, even through the summer months, quite equal to the supply, and prices were well maintained; and during the keen frosts of the last few weeks merchants and colliery proprietors have found it quite impossible to keep their customers fully supplied. It is only in the land-locked centres, where collieries are worked in conjunction with iron works, a large proportion of their output of fuel being consumed in the melting and manufacture of iron, that, owing to the heavy fall in the value of that commodity, great difficulty is experienced in meeting the increased cost of production. Miners' wages have been generally advanced during the year 20 per cent.

Letters to the Editor.

OUR BIG GUNS, AND HOW THEY ARE MADE

To the Editor of "Industries."

Sir,—The letter in a recent issue by Lieutenant Gubbins directs attention to a matter which ought to have been fully considered by our military authorities long ago, especially after the opinion of such a high authority as Sir William Siemens on the point. Any one who thinks about the matter must see that the present method of shrinking on the rings of guns, which are subsequently to be expanded by heat when used, is wrong, and after a certain number of charges the guns are sure to crack, the number depending, to a very large extent, on the state of stress of the different parts of the body of the gun. The method suggested by Sir William Siemens, and which, I believe, was carried out by the Government of the United States in the manufacture of cast-iron guns with highly satisfactory results, may be a little more complicated in practice than the present one, but that would be more than balanced by a distribution of stress which would be highly advantageous to the guns.

Perhaps some of your readers who have had practical experience in the manufacture of guns will say whether there are any great difficulties in carrying out Sir William Siemens' suggestions, and then you may be in a stronger position to call upon the authorities to explain why they have so long ignored them.

Yours, &c.,
London, 7th January, 1891. C.E.

IMPROVEMENTS IN THE MANUFACTURE OF NITRIC ACID.

To the Editor of "Industries."

Sir,—I am much obliged to Mr. Guttmann for his reply to my inquiries, and fully appreciate the advantages which his process possesses. My interest in the matter has led me to refer to sundry German technical journals, and look up the criticism of Mr. Andersch, which I find appeared in the *Zeitschrift für Angewandte Chemie*. Pursuing my investigation, I came across a reply by Mr. Guttmann to that criticism in a later number of the same paper; but in that reply the main point at issue between the disputants—namely, the saving to be effected by the process—is not satisfactorily settled. Its success must depend on its cost, and when one finds Mr. Andersch asserting that the plant on which Mr. Guttmann proposes to save 80,000 marks costs only 30,000 marks altogether, and, getting no more conclusive answer to this statement than is given by a doubt being cast on the adequacy of the plant, and therefore on the accuracy of the estimate, one is naturally desirous of more definite information.

Yours, &c.,
Bertram Blount.
Laboratory, Broadway, Westminster, S. W.,
8th January, 1891.

THE TRIPLE EXPANSION ENGINES OF THE S.S. "CITY OF PERTH."

In our two-page supplement this week we give illustrations of the triple-expansion engines of the s.s. "City of Perth," constructed by Messrs. John & James Thomson, Glasgow. These engines indicate 2,250 h.p., and have cylinders 26½in., 44in., and 72in. diameter, and 48in. stroke. The working pressure is 160lb. per square inch, and the steam is supplied by two single-ended boilers fitted with Howden's system of forced draught. The boilers are 14ft. 6in. diameter by 11ft. 6in. long, with three furnaces each of 42in. diameter. The total fire-grate area is 99 square feet, and the total heating surface 4,260 square feet. The air for the forced draught is supplied by one of Messrs. Drysdale's 60in. fans driven by a belt from a vertical engine made by the same firm. There is also a spare engine. The main engines are fitted with Morton's valve gear, and the valve casings are on the cross-centre lines of each engine, thus making the engine as compact as possible. The high-pressure engine is fitted with a piston valve; the intermediate engine, a double-ported slide valve; and the low-pressure engine is fitted with one of Thom's double-ported Trick valves. The condenser has a surface of 2,701 square feet. The circulating water is drawn through the tubes by a double-acting pump, which, along with the air-pump, two bilge and two feed pumps, is worked from the intermediate engine by levers. The feed pumps are arranged to pump either direct to the boilers, or to one of Weir's patent feed-water heaters, from which the feed water is discharged into the boilers by a pair of direct-acting pumps. There is also a Weir's 14-ton evaporator to supply any loss of feed water. The crank shaft is 13¾in. diameter, and is made of wrought iron with steel crank pins. It is in three pieces, and is supported by four bearings, the outer two of which are 1ft. 8in. long, and the inner ones 2ft. 6in. long. The cylinder castings are of cast iron, but the pistons are of steel, and are fitted with Lockwood & Carlisle's rings. The high pressure and intermediate cylinders are fitted with hard close-grained liners, and the intermediate cylinder has a loose valve-face. The cylinders are supported on the front of the engine by four wrought-iron columns, to which the upper shaft brackets are fastened. These brackets are of steel. The starting engine is made by Messrs. W. H. Allen & Co., of London, and has a cylinder of 10in. diameter by 16in. stroke, and is found very efficient. The thrust-block has six rings of the horseshoe type, and is provided with very ample surface.

The "City of Perth" was built by Messrs. Workman, Clark, & Co., Ld., of Belfast, for Messrs. Geo. Smith & Sons, Glasgow. Her dimensions are:—Length, 361ft. 7in.; breadth, 42ft. 7in.; depth, 26ft. 4in., with a gross tonnage of 3,427 tons. She is classed 100 A1 in Lloyd's Registry, and is built considerably above their requirements. The vessel is of the three-decked type, having two steel decks, the upper being sheathed with teak, and having a poop bridge and topgallant forecastle. The officers are housed under the forecastle, the engineers in wing-houses under the bridge, and the crew in the poop. The ship has five cargo holds, and is divided into eight water-tight compartments. The vessel is fitted with Harrison's steam steering gear and Harfield's windlasses, Sir Wm. Thomson's standard compass and patent sounding machine. Electric light is fitted throughout by Messrs. Paterson & Cooper, of London. The holds are provided with seven steam winches and derricks for the working of the cargo. Captain Anderson's "hold-handy ladder" is fitted for examining the hold and for assisting in stowing the cargo. On a recent trial trip against the tide the speed was at the rate of 12 knots per hour, and with the tide 12½ knots.

THE PHENOMENA OF THE DEPTFORD MAINS.

By J. Swinburne.

II.

(*Concluded from page 40.*)

Among those who have discussed this subject, Mr. Kapp alone holds that the resonator effect occurs at all periods, so that I have dealt with that point separately. The other cases, alleged to be possible, have been gone over more than once, both by Mr. Glazebrook and Dr. Fleming, so that it will be better to discuss the explanations in order.

In the first place, the *Electrical Review* suggests that the Deptford transformer is wound wrongly. This is an eminently commonsense explanation, which commends itself to any one who has made transformers, and knows how frequently errors arise in practice. Even experienced gas-meter inspectors continually make mistakes in taking the indications of revolution counters, and such a reading as 399 is frequently put down as 499 or 409. I do not think, however, in this case that there can be such an error.

Digitized by Google

Turning, therefore, to effects due to capacity and resistance, we may best begin by finding exactly, or approximately, what quantities we have to deal with. Dr. Fleming* gives the specific inductive capacity of the dielectric, brown paper and ozokerite, as 3·5. This seems very high, as paraffin wax is generally given as from 1·9 to 2·5; it would be interesting to learn how this was obtained, as absorption may have interfered with the accuracy of the readings. We may assume, however, that Dr. Fleming's values are correct, as his carefulness is well known. The resistance given is high, being twice that due to the copper, which goes to show that the joints must be bad. I do not know whether the resistance due to bad joints would not fall when there is a current, but we may again take Dr. Fleming's figures as accurate. Arranging them for reference, we have for a seven mile trunk main—

Self-induction.....	0·002	henry.
Resistance	2·275	ohm.
Capacity	2·057	microfarad.
Frequency	67	periods per second.

Professors Ayrton and Perry have often lamented that electrical engineers have so little idea as the values of self-inductions met with in practice; I think there is the same want of familiarity with capacity.

Take first the case with the pressure of 10,000 volts at the London end. First suppose the circuit at London open, so that there is no load. The current into the cable is 10·8 amperes. The self-induction of ·002 and the capacity are both distributed, but even if put in series, the self-induction would only account for 9 volts out of 10,000. I think, therefore, the self-induction of the main may be neglected. To give 2,000 volts, which is, I understand, about the rise observed, demands a self-induction of 0·44 henry.

This self-induction is enormously great for such a circuit. It would have to be in the transformer or in the dynamo. Professor Ayrton stated that the rise was confined to the London side of the Deptford step-up transformer, so this enormous self-induction would necessarily be somewhere in the leads, as a transformer cannot alter its ratio of transformation at ordinary frequencies without an alteration of the primary current. It is easier to believe Professor Ayrton was misinformed than to find any explanation for the alleged phenomenon.

It might be said that self-induction of half a henry or so is lurking in the transformer. Supposing the transformer to be wound one to one, and neglecting the exciting or magnetising current component, the primary and secondary current would be equal and opposite. It would then make no difference if the circuits were joined in series in opposite directions, so that the transformer was like a choking coil with half its turns arranged backwards. It would then act as a choking coil to the very small extent due to the waste induction. This waste induction always exists in a transformer, and causes a "drop." The "drop" in a well-designed transformer for fifty lights or so should be a fraction of 1 per cent., in a very large transformer it should be much less. It can be easily calculated, but I have not the dimensions of the transformers under discussion. Assuming the drop to be 0·25 per cent., at a full load of 300 amperes, which is what the mains carry, according to Mr. Ferranti the transformer would behave as if it had a self-induction of 0·006 henry in the 10,000 volt circuit. The transformer cannot, therefore, produce the effect.

As to the dynamo, there is either armature reaction or self-induction. If there is armature reaction, which accounts for the variation of pressure, the theory as given in my Physical Society paper, is correct. Even if the armature reaction is disguised under the name of self-induction, this theory remains correct. If it is desired to call it self-induction, we can, of course, find a value, which, at this particular load, would give the same external results as armature reaction. To produce a rise of pressure of 500 volts when the machine is excited to give 2,000 volts in open circuit needs, with a capacity current of 43 amperes, a self-induction of 0·0275 henry. That the effect is due to the dynamo thus seems quite possible and reasonable. It also accounts for the effect disappearing when the dynamo is excited up to 10,000 volts, and coupled direct to the mains. The percentage rise is then only one-sixteenth of what it was before. This is Dr. Fleming's case (I.), and Mr. Glazebrook's case, giving R_2 an infinite value. Mr. Kapp also discusses it with reference to his Fig. 10, except that his values for L C and R do not apply. He says, however, that the dynamo self-induction cannot be large enough to have this effect. It may, however, be "somewhat" increased by the use of a step-up transformer. He appears to regard a step-up transformer as adding to the self-induction of the circuit as if it were a choking coil. It cannot do this perceptibly, and it cannot increase the "self-induction" of the dynamo, but by multiplying the armature current with a given capacity by four, and necessitating weak fields, there results an arrangement which admits of great armature reactions.

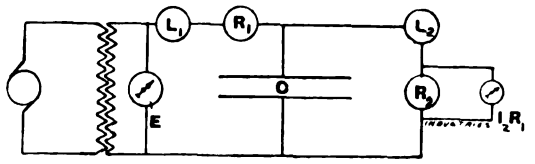

Fig. 1.

Take now the case with, say, 2,000 30-watt lamps on in London. This is equivalent to a resistance of 1,666 ohms put across the London end of the main. This corresponds to Dr. Fleming's case (II.), and Mr. Glazebrook's case with $R_2 = 1{,}666$. The self-induction in the London transformers is not as small as at Deptford, because there are two sets of step-down transformers. We may, therefore, go so far as to write L_2 as equivalent to 0·02 henry put in the high-tension circuit. If there are 10,000 volts on R_2, i_2, the current which is transformed down and used on lamps is 6 amperes. The pressure needed to overcome the self-induction L_2 is then 50 volts, and the pressure on the mains, or on the condenser, is only increased one-tenth of a volt in 10,000. L_2 might as well have been taken as zero. The condenser current is still 10·8 amperes, and, taking L_2 as zero, the total current i_1 at Deptford is 12·3 amperes. The step-up transformer being taken as before, we still have only the dynamo to come upon. If it has a self-induction $L_1 = 0{\cdot}0275$, which acts as 0·44 in the high-pressure part of the circuit, the rise of pressure is only 76 volts less than before. Taking 25 amperes used at London, which is about the full load of the machine when used with a four to one step-up transformer, we have 4,820 volts spent on the "self-induction" of the armature. The modulus of 8,000 and 4,620 is 9,236, so there is still a rise of 764 volts.

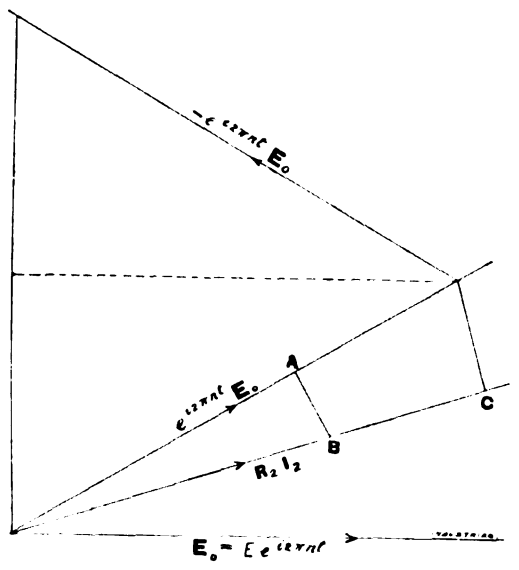

Fig 2.

Mr. Glazebrook merely gives a general statement of the theory of two parallel circuits, each with self-induction and resistance, with a condenser in shunt to them, and an alternating electromotive force in one of them. His working may be simplified by translating into vector or quaternion methods. Let E Sin $2\pi nt$ or E Cos $2\pi nt$ be the instantaneous electromotive force in one of the circuits, say, the pressure at Deptford. If the effective pressure is 10,000 volts, the maximum value is 14,140 = E (Fig. 2). Represent this by the vector $E_t = Ee^{i2\pi nt}$. When $t = o$ suppose this vector is E_o, differing in direction but not in length. Then if the instantaneous electromotive force follows a sine law, $E \text{ Sin } 2\pi nt = E\frac{1}{2}(e^{i2\pi nt} - e^{-i2\pi nt})$. To get this add $Ee^{-i2\pi nt}$, which reaches to Y, then $1/2\ \overline{OY} = E \text{ Sin } 2\pi nt$. E Cos $2\pi nt$ is similarly found. The numerical relation between the pressure on the lamps, or R_2, to that at Deptford, is given by Mr. Glazebrook thus:—

$$E = \Big[(R_1+R_2)^2 + (2\pi n)^2(L_1+L_2)^2 - 2C(2\pi n)^2 \Big\{ R_1^2L_2 + R_2^2L_1 + (2\pi n)^2(L_1+L_2)L_1L_2 \Big\} + C^2(2\pi n)^2(R_1^2+(2\pi n)^2L_1^2)(R_2^2+(2\pi n)^2L_2^2)\Big]^{\frac{1}{2}} I_2,$$

which may be altered into

$$E = (R_1+R_2+2\pi in(L_1+L_2)+2\pi inCR_1R_2+(2\pi in)^2 CR_1L_2+(2\pi in)^2CL_1R_2+(2\pi in)^3CL_1L_2)I_2.$$

Separating the coefficients of I_2 with odd and even powers of i we have

$$E = \Big\{ R_1+R_2-(2\pi n)^2CR_1L_2-(2\pi n)^2CR_2L_1+i\big(2\pi nL_2+2\pi nCR_1R_2-(2\pi n)^2CL_1L_2+2\pi nL_1\big)\Big\} I_2.$$

Taking R_2, the lamps, as, say, 1,000 ohms, and L_1 as ·001, most of the components of E become inappreciable, and we have a simple case of condenser and resistance in parallel on a dynamo. If the dynamo has armature reactions, which are equivalent to ·44 henry under the particular circumstances, we must treat the case as if $L_1 = ·44$. We then have

$$E = (802 + i \cdot 190)\, I.$$

Along E_t mark off O A = 802 in any convenient scale; from A draw A B = 190 in the direction $-i\,\overline{OA}$; from the end of E_t let fall a perpendicular on O B produced, meeting it at C, then $\overline{OC} = R_2I_2$. If we want to see the effect of varying any of the values, such as the capacity of the condenser, we can first find R_2I_2, when C = O, and then operate again on this vector by means of the terms involving C.

Mr. Glazebrook's case of infinite value of I_2 cannot occur at Deptford. It is when R_1 R_2 are each equal to zero, and when

$$C = \frac{L_1 + L_2}{n^2\, L_1\, L_2}$$

This is merely the case of the resonator again, with two self-inductions in parallel with the condenser instead of one. Two self-inductions coupled in parallel act as one self-induction, whose value is found like that of two conductivities coupled in series. I think Mr. Heaviside has called the reciprocal of the inductance "permittance"; to get the joint permittance of two permittances placed in parallel we add them like conductivities. I do not remember, however, whether permittance is the reciprocal of inductance or of impedance; whichever meaning is given, permittances can be combined like conductivities.

Mr. Glazebrook goes on to say that Mr. Mordey's difficulties with his armature may be accounted for by his having values which cause resonance. I think Mr. Glazebrook can hardly have any idea of the quantities dealt with. The resistance in circuit with a Mordey machine is, say, 100 ohms, and the capacity of the coils of the armature, if such an expression can be used, is infinitesimal. The strip, if unwound, has a total area of only a few square feet, and neighbouring turns are separated by only a volt or two. It would seem more likely that the armature breaks down more easily than the average coil, just as a chain breaks more easily than the average link. Similarly the capacity of the transformers may be left out of account as quite inappreciable in comparison with two or three microfarads.

Beyond giving a complete statement of the case of two parallel circuits with a condenser in shunt to them, I cannot see that Mr. Glazebrook's paper explains the Deptford phenomena at all. No appreciable value of L_1 can be found, unless the armature reaction is called self-induction, and it is then merely a general statement of the theory given in my Physical Society paper.

Dr. Fleming goes over the same ground in a different way, but does not show the existence of any appreciable L_1, unless it is taken as in the dynamo. He also discusses the case of capacity, resistance, and inductance distributed along a main, and gives an equation taken from a paper of Mr. Heaviside's. I have not this paper at hand, and object to working with any formula until I have worked it out for myself. As given by Dr. Fleming, the formula conveys no meaning, as G, H, and θ make their appearance without any introduction.

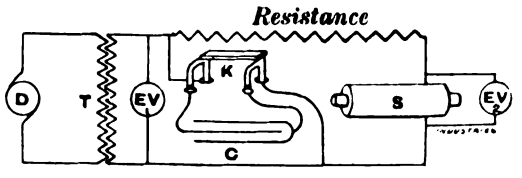

Fig. 3.

Professor Ayrton gives the diagram, shown in Fig. 3, and says that when the condenser is put in circuit the reading on the voltmeter EV1 is not increased so much as that on EV2; and says he is glad to find Mr. Glazebrook agrees with him. Mr. Glazebrook's paper does not in the least bear out the results of such an experiment as that given by Professor Ayrton. The London voltmeter is connected across a self-induction S instead of a resistance. The result is impossible also. The reading of the Deptford voltmeter, placed as shown in the diagram, is to that of the London voltmeter as the modulus of R and $2\pi nL$ is to L, and this ratio remains constant whether the condenser is on or not. I can only suggest that Professor Ayrton has confused an equal percentage increase of reading with an equal increase, or that the speed altered, or that his readings or instruments are inaccurate.

THE KIOTO CANAL, JAPAN.

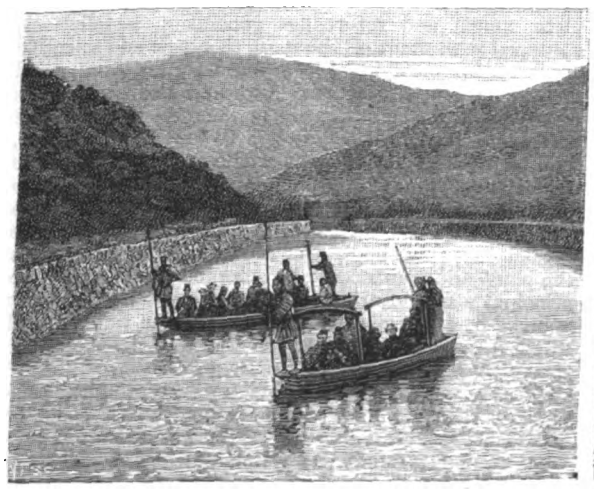

Fig. 1.—Entrance to the Canal from Lake Biwa.

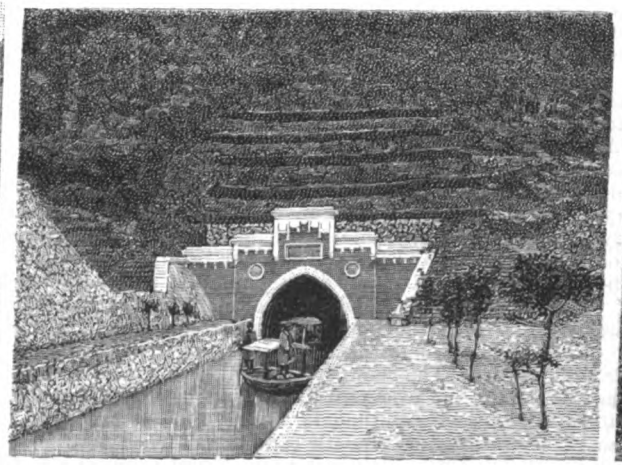

Fig. 2.—Entrance to No. 1 Tunnel.

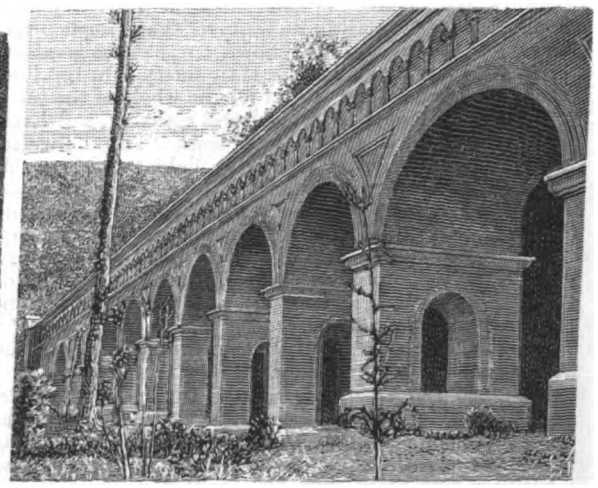

Fig. 3.—Aqueduct Carrying Canal across a Valley

THE KIOTO CANAL, JAPAN.

Early last year (see *Industries*, Vol. VIII., page 80) we published a map showing the district between Lake Biwa and Kioto, and the line of the Kioto Canal, together with a general description of the undertaking. Since that time the construction of the canal, which has occupied almost five years, has been completed, and we are now enabled to give three views of the completed canal, for which we are indebted to our contemporary, *La Nature*. Fig. 1 shows the entrance to the canal at the extremity of Lake Biwa. This entrance to the canal was formed by reclaiming about 1,000ft. of the lake, and forming a breakwater to protect it and ensure still water.

The canal, which has a length of 6⅜ miles, has to pass through several ranges of mountains, and this is effected by means of three tunnels, the length of which are 2,680, 137, and 934 yards respectively. These tunnels are of the section shown in Fig. 2, and have a breadth of 16ft. and a height of 14ft. They are lined throughout with masonry. Fig. 2 shows the entrance to No. 1 tunnel, and is the second longest in Japan. At a distance of about 5¼ miles from Lake Biwa the canal is divided into two portions, one joining the River Kamagawa, and the other leading northwards to Kogawa, the northern extremity of the city of Kioto. The second portion of the canal, after passing through a tunnel 150 yards long, crosses the valley of the Imperial Tombs by a handsome aqueduct, which we show in Fig. 3. This aqueduct is 300ft. long and consists of fourteen arches. For a more detailed description of this canal we would refer our readers to the former description given in *Industries*.

THE PROGRESS OF ELECTRICAL ENGINEERING IN 1890.

II.

(*Concluded from page* 41.)

The various dynamo makers have been very busy supplying plant for stations at home and abroad.

The Brush Electrical Engineering Company have been turning out large numbers of Mordey alternate current machines. Their works at Belvedere Road have been fully occupied, and the Falcon Ironworks, of Loughborough, are also in full swing making engines, tramway carriages, and everything connected with electrical engineering, as well as with the original province of the business before it was taken over by the Brush Company.

Messrs. Siemens have been supplying numerous large drum armature machines for station work. Some of these, such as those recently supplied to the St. James's and Pall Mall Station at Mason's Yard, are particularly fine machines. These have air ventilation through the bodies of the commutators.

Messrs. Crompton & Co. have been confining their attention to direct current dynamos. They have supplied several large machines to many of the London electric light companies and a large four-pole machine for smelting work. This firm have, as is well known, a private electric power station for lighting the town of Chelmsford. There are two systems in use, one with alternate current parallel supply and transformers, and a high tension direct current for series arc lamps. Messrs. Crompton & Co. also fitted up a tramway along Southend Pier within a month from the date of order, which is decidedly quick work. The Crompton-Howell battery has been making great strides, and has succeeded beyond the expectations of the most sanguine.

Messrs. J. H. Holmes & Co., of Newcastle-on-Tyne, have been kept extremely busy, their output in dynamos being about double that of any previous year. They have sold during the past year 152 dynamos, having an average output at usual speeds of 18,000 watts each, or a complete output of nearly three million watts. The demand for these machines has increased so rapidly that, although the works have been doubled in size during the year, the firm have been obliged to decline some urgent orders. Messrs. J. H. Holmes & Co. have, in addition to supplying other electrical engineers with dynamos, completed sixty-six installations of electric light in mills, factories, residences, and steamships.

Messrs. Johnson & Phillips have turned out a large number of dynamos both for continuous and for alternating currents. Among the former have been machines for the Duke of Northumberland, the General Post Office, Birmingham, the National Museum and Libraries, Dublin, Madame Tussaud's Exhibition; whilst among the latter may be mentioned complete sets for the Hong Kong Central Station, a machine for the extension of Keswick Central Station, and several others which have been exported to the Continent. Eleven sets of the Kapp central station continuous current dynamos are in various stages of erection for St. Pancras, and will be delivered early this year. The accumulator and vulcanised rubber cable departments have been kept full of work, and extensions have been found necessary to both. The business in the Brockie-Pell arc lamp department has been highly satisfactory, and shows a very large increase over the previous year.

Messrs. Laurence, Scott, & Co., of Norwich, have been well supplied with orders for dynamos and motors, and among others nearing completion is a large dynamo to generate 2,500 amperes, to be used in the reduction of aluminium, also a 40 unit continuous current transformer just completed for the Chelsea Electricity Supply Company, and a large 600 lighter dynamo for Messrs. J. & J. Colman, of their city. They have within the last few months introduced a specially-wound accumulator dynamo that will charge cells and supply constant e.m.f. to lamp mains independently or at the same time. These are said to work well. They have also worked out a meter which is soon to be on the market. Their installation department has also been kept fully employed.

Messrs. Paterson & Cooper have been supplying large numbers of dynamos for installation work, their output being greater than in any previous year. They have also worked out an alternate current arc lamp of which reports are favourable. Though most of their dynamos are supplied to contractors, they have themselves carried out several important installations.

Messrs. Royce & Co. have slightly more than doubled their plant during the past year, and have been running night and day. They have supplied many machines for ship lighting and colliery work, and for private installations.

Messrs. C. A. Parsons & Co. have during last year turned out plant of no less than 1,400 electrical horse-power, consisting of direct and alternating current dynamos, and their well-known turbine electric generators.

Messrs. Browett, Lindley, & Co. have been extremely busy with engines for electric lighting, and among these were five pairs of 100 h.p. compound condensing engines for lighting a large city abroad, as well as about forty other installations of electric light, many of them for ship-lighting. The business has been turned into a limited liability company, to enable the proprietors to extend their facilities for production, as they have for a long time had more orders offered than they could accept, chiefly for electric lighting.

Messrs. Ransomes, Sims, & Jefferies have supplied a number of engines for various private installations, and have also made a 30 h.p. compound engine for Fareham, as already mentioned. One of this firm's long-stroke 10-horse engines was employed for driving the exhibit of Messrs. Norman & Son at the recent Edinburgh Exhibition. They have also done a considerable export trade in engines for India and elsewhere.

Messrs. Robey & Son have had an increased business in electric light engines for ship, private, and central station work. They now make their well-known triple-expansion Corliss engines up to 1,000 h.p.; 200 or 300 h.p. is, however, the favourite size, and these smaller engines are to be seen in the Newcastle Central Station and elsewhere.

Messrs. Tangye have supplied numerous engines for station and ship lighting. They make a fast-running vertical engine, which meets with considerable favour for direct driving.

Installation Work.

There has been great pressure in the wiring of houses during the last year, as so many companies are growing rapidly, and the increase of customers has been very great.

Messrs. Drake & Gorham have been busily employed in installing isolated plants. For instance, they have put electric light plant in the new police buildings, capable of supplying 1,500 lamps of 16 c.p. They have also lighted Madame Tussaud's. A gas engine and Kapp dynamo were used. The foundations present some novelty in the way they are arranged to prevent any noise from the gas engines. They have also carried out some twenty private installations.

Messrs. Paterson & Cooper have carried out a large number of ship-lighting installations. Amongst the vessels have been the "Peruvian," "Brazilian," and "Parisian," belonging to the Allan Line; the "City of Vienna," the "City of Venice," the "City of Perth," and "City of Dundee," for the City Line; and the "Arranmore" and "Tuska," for the Clyde Shipping Company. They have now in hand the lighting of the "St. Nicholas" and "St. Dunmow," the "America," and the new boats for the Manchester, Sheffield, and Lincolnshire Railway Company.

The Liverpool Electric Supply Company have fitted up a very large number of lights for private installations, and have equipped several ships, one of the most important being the White Star steamer "Majestic," which has about twelve hundred 16 candle-lamps, with four combined sets of engines and dynamos, each capable of supplying 400 lamps at one time.

Messrs. Woodhouse & Rawson have been very busy. In the Yorkshire district alone forty-two installations have been carried out by their Bradford branch. In the Lancashire district they have also been very busy. In London they have done work for the Savoy Mansions, Crosse & Blackwell, Clowes & Sons, Smith & Sons, and many other well-known firms.

General Work.

Messrs. Spagnoletti & Crookes have done a large business, consisting of the manufacture of railway, telegraph,

Digitized by Google

and block instruments, and general railway appliances, together with many sets of C. E. Spagnoletti's patent electric locking block apparatus. This system has been employed on the Metropolitan, Great Western, and other railways, and has recently been fitted upon the City and South London Electrical Railway, so that people may travel on this line with the knowledge that the greatest precaution has been taken for their safety. On this line they also secured the contract for the whole of the telegraph arrangements, both block and speaking, and have had the greatest success with the work. They have also made a great quantity of electric light requisites. A considerable amount of work has been done for the trade in railway instruments, fire alarms, &c. Many thousands of battery cells have been made in their factory during the past year, and this trade seems to be a very increasing one. They have manufactured a fair share of ship-lighting plant, and supplied measuring and test instruments for cable work.

Messrs. Sharp & Kent, Woodhouse & Rawson, the Electrical Fittings Company, the General Electrical Company, and the various firms who supply instruments, switch boards, lamp fittings, lamps, carbons, and all the thousand and one accessories, have been busy trying to keep pace with the demand. On the whole, last year has been very prosperous, and there is a general feeling that this year will be even more so.

Messrs. Berend & Co. have been doing a large business in the various measuring instruments made by Messrs. Hartmann & Braun. The demand for these is very rapidly increasing. These instruments are all carefully designed to meet the actual requirements of electric light engineers. They also find increase of business in enamelled reflectors and the numerous electric requisites which they import from Germany.

Messrs. Woodhouse & Rawson have been developing rapidly. They have purchased a large engineering works at Kidsgrove, near Stoke-on-Trent, for boilers, large dynamos, cranes, &c. They have also taken over the launch-building business of Mr. W. S. Sargent, of Chiswick. There they have built several of the best electric launches. Their supply department has also been kept exceedingly busy, providing every conceivable article needed by engineers.

Messrs. Goolden & Co. have supplied Messrs. Sharp & Kent with 160 h.p. dynamos, engines, boilers, &c., and eight underground mains to the Houses of Parliament. They only had three weeks to complete this order, and did so with success. They have also supplied dynamos to the Westminster Company, as already mentioned, and boilers for the St. John's Wharf Station. They have also large orders in hand for Brighton and elsewhere. Messrs. Sharp & Kent are contractors for these.

The General Electric Power and Traction Company have for their main object electric traction and general power work, but they in no wise confine themselves to these branches. Mining work has been exceptionally brisk, and installations have been erected in England, Wales, Scotland, the Continent, Asia, Africa, and Australia. Without going into details, it may be mentioned that almost the whole range of mining work has been successfully accomplished by the "Immisch" plants, winding, hauling, pumping, fan driving, rock drilling, &c., having been carried out in different pits, and in nearly all cases the plants have been arranged on the compound parallel system so as to be adapted for both lighting and power. The aggregate horse-power supplied during 1890 in dynamos and motors for this purpose is very nearly 1,000. During the past summer the company had launches both on the Thames and on the Union Canal at Edinburgh during the late Exhibition. The total number of passengers carried at Edinburgh was 100,000, and the result commercially was thoroughly satisfactory. On the Thames some twelve launches were kept for hire, and, although the season was a bad one, they were patronised by the public to a large extent. The general work of the company during 1890 was far in excess of that of the previous year, and shows a large increaes in the demand for motors suitable for central stations, and motors for special machine tools have been in fair demand.

THE LONDON SMOKE AND FOG PLAGUE:

ITS ORIGIN AND DANGERS, AND A PROPOSED SOLUTION FOR ITS REMEDY.

By B. H. Thwaite, C.E., F.C.S., A.M.Inst.C.E.

II.

(*Concluded from page 42.*)

Year by year the fertilising value of our coal resources is lost to the nation. This loss is enormous and deplorable, and if the familiar adage that "wilful waste makes woeful want" is applicable to nations, our future will be woeful indeed. The nitrogen in its compound form as ammonia sulphate is extremely valuable to agriculturists, but, in flagrant violation of the great natural order of the conservation of energy, tens of thousands of tons of this fertilising agent are annually thrown into the atmosphere of London whilst we ransack Chili and Peru for the mineral substitute. The annual value of the mineral sodio-nitrate imported for the fertilisation of our soil may be taken to equal 650,000 tons, of the value of 6½ millions sterling. Doubless much of this is re-exported to the Continent and elsewhere. But if, instead of this agent being imported, we abstracted the nitrogenous treasures of our coal deposits, a great part of this 6½ millions sterling would be saved. Even were the nitrates recovered from the twelve million tons of coal used annually in London, this would be almost equal to half the amount of the foreign nitrates imported. It may be taken as a fair ratio that there is recovered from 16 tons of coal one ton of ammonia sulphate, so that the London coal consumption carries with it at present the burden of a national loss of 750,000 tons of fertilising agents, less that recovered by the gas companies. The manurial value of this artificial fertiliser recovered from coal was proved by the remarkable Rothamstead experiments. They showed that under fairly satisfactory climatic conditions the artificial fertilisers (ammonia salts) are capable of giving a much larger crop, both of grain and straw, than the farmyard manure.

Besides the nitrogenous loss there are the recoverable tar compounds, which possess—thanks to the discovery of our chemist Perkins—valuable constituents. The weight of tar lost by the annual London coal consumption, deducting coal used by the gas companies, may be estimated to equal 400,000 tons, of an approximate value of £400,000.

The weight of fuel lost in transmission by rail and by sea would not be over-estimated at ½ per cent. of the weight, or 60,000 tons, equivalent to a money loss of £45,000. It is impossible to estimate the wear and tear of the rolling stock in carrying coals, but it is very considerable, as the trucks have to travel both loaded and empty. The cost of carrying the twelve million tons of coal to London by rail and by sea is, however, not great. It may here be stated that the rate for railway carriage of coals fixed by Parliament is so low that, taking into account the double journeys to be performed, the profit on this class of goods cannot be very great; indeed, in the instance of the Great Western Railway, the carriage of coal is said to involve a positive loss of 0·4d. per ton per mile. The charge for carriage may be reckoned at 0·838d. Taking the average distance over which the coal has to be transmitted to be 100 miles, then the amount paid for railway carriage of coal to London equals £2,780,000.

By sea the annual cost of shipment of the 4,000,000 tons assumed to be carried at the rate of 7s. per ton, and with a cost of 5d. per ton unloading, will equal £1,566,000. The cost of shipment is great because, as in the case of transport by rail, great wear and tear are involved, and the cost has, in both instances, to cover the expense of the return journey.

If we attempt to calculate the profits of the various merchants, middlemen, and carters, adding 3s. per ton for the former and 2s. 6d. per ton for the latter, the cost of the 8,000,000 tons used, in addition to the 4,000,000 tons used by the gas companies, would be equal to £2,200,000.

We can now approximately estimate the expense of merely transmitting the twelve million tons of coals to the inhabitions of the London metropolis. It reaches the colossal figure of £6,591,000 annually. If to this we add the value of the nitrogenous and tar or hydrocarbon constituents of the coal now wasted, the total expands to £9,535,400.

The Solution.

The solution of the problem is to supply London with gas generated in the coalfields of South Wales, South Yorkshire, and Staffordshire.

A great part of the enormous annual expenditure in bringing coals to London would be saved by carrying out in its entirety the project first suggested in the author's lectures at Sheffield, Manchester, and Halifax, on the subject of "Gaseous Fuel." This project is an adequate imitation of the natural gas system of distribution in use in Pennsylvania and Ohio. The gas issuing from the natural gas wells at pressures equal to 500lb. to the square inch, is led by pipes to distances of 70 miles from the place of production—indeed, the mains for supplying this gas for industrial and domestic purposes exceed 2,000 miles in length. The advantage of gas for all purposes where heat is required is fully appreciated in the area of the natural gas distribution, and its displacement of solid fuel or coal in Pittsburgh has transformed the atmosphere of this industrial centre. That there should be no difficulty in distributing the gas will be evident from the fact that in London alone there are 4,000 miles of gas mains.

Instead of the natural gas, which the author has reason to believe may yet be discovered in England, it is proposed to erect on the coalfields, in a central position, in South Yorkshire, Staffordshire, and South Wales (as shown on the map given on page 67), complete cupola and retort gas generating installations, equipped with plant of the most economic and scientific character for purifying the gas and for recovering and treating the hydrocarbons (tar) and the nitrogenous constituents. The gas would be compressed by special machinery into storage cylinders to very high pressures, and from these cylinders it would be supplied to the steel trunk mains of suitable capacity and strength to lead the gas without loss to the Metropolis. In the first instance, the mains would be only of adequate capacity to fully supply the Metropolis, but afterwards the plant and mains could be enlarged so as to feed the principal manufacturing centres traversed by the trunk mains. The velocity with which the gas would travel would depend upon the sectional area of the mains, but the velocity would not exceed 4ft. per second.

All the proved arrangements for regulating the pressure of the supply in use in Pennsylvania could be adopted. The arrangements of the gas generator, purification, and residual extraction stations would be as follows:—

On an appropriate accessible and central position in the Yorkshire coal fields a plant would be erected capable of converting 3,000,000 tons of coal per annum for lighting purposes, and 1,500,000 tons of coke and 2,500,000 tons of coal per annum for heating and industrial purposes. On the Staffordshire coalfield, appropriately situated and connected with the main trunk line of pipes, there would be constructed a fuel or heating cupola gas generating plant capable of dealing with 4,000,000 tons of coal per annum. In a central position in the South Wales coalfield, and within a short distance from a petroleum storage plant, which would be placed in such a position that the oil could be run direct from tank steamers, there would be erected an enriched water gas generating plant, using the Welsh anthracite for this purpose, and crude American or Russian petroleum oil. This gas would be enriched sufficiently to raise the gas from the Yorkshire station to the required photometric standard.

The main trunk line for leading the illuminating gas from Yorkshire would be joined to the South Wales trunk pipe somewhere in the neighbourhood of Coventry. In the distance between this position and the Metropolis the enriched South Wales gas would be diffused with the poorer illuminating gas generated at the Yorkshire station.

Near the Metropolis, containers would be provided for storing the fuel gas at carefully selected positions, by which the heating gas could be distributed where required in separate and high-pressure mains. The existing gas holders could be utilised for storing the illuminating gas. In all industrial operations, where coke is required for manufacturing and industrial operations, cheap heating gas could be provided, which would be equal to, if not much superior, to coke. For all domestic purposes—for heating and cooking, and for gas engines, &c.—the use of a cheap fuel gas would be a priceless boon; it would relieve the household of one of its most trying difficulties, and command the gratitude of the housewife, whilst it would give the workman facilities for obtaining cheap power that might convert his struggling life into a prosperous one. In fact, the abundant supply of cheap fuel gas would mean a saving, in hard cash, of nearly ten millions sterling a year, and convert this city of smoke and fog, after a few years, into one of the most magnificent cities in the universe in point of architectural grandeur.

Then, as to its hygienic advantages, the system would destroy the edge of the scythe of King Death in his costume of fog and smoke, and instead of the London citizen hurrying off to the Riviera and expending his wealth to support foreigners, he would stay at home. Apart from the one great blot of smoke, the sanitary arrangements of London are very good, and better than those of any Continental city.

What will the Project Cost?

The following is an estimate that will give a sufficiently approximative idea of the cost of the project. It will probably be found to be rather over than under the mark:—

Yorkshire installation	.....	£4,400,000
Staffordshire „	.....	3,140,000
South Wales „	.....	2,140,000

The total cost of the plant for dealing with twelve million tons of fuel per annum would, therefore, not exceed £9,680,000.

The cost of the main trunk lines and metropolitan distributing pipes is more difficult to estimate. It is approximated as follows:—

Digitized by Google

Land	£1,500,000
Two sets of trunk lines	1,112,500
Metropolitan distributing lines	1,612,500
The total cost would therefore equal	£4,225,000

Some idea of the magnitude of the existing London and suburban gas companies may be obtained from a consideration of the following salient and startling statistics.

The capital actually invested amounts to close on £17,000,000 sterling, of which nearly £15,000,000 sterling represents the capital invested in the Metropolitan companies. The annual income of these companies amounts to about 5,000,000 sterling, of which £1,500,000 represent net profits. Assuming these companies were brought out at the market value of to-day, taking into consideration the increasing development of electric lighting, the price paid would probably reach £30,000,000 sterling. The purifying and retort and residual recovery plant could be bodily removed to the new coalfield generating stations, which would mean a reduction in the cost of generating installations of at least £2,000,000 sterling.

The actual expense of the scheme can now be fairly realised, and stands as under :—

Amount payable for the Metropolitan gas undertakings	£30,000,000
Cost of coalfield generator installation, less £2,000,000 for present or existing plant	7,680,000
Cost of main trunk lines land, and Metropolitan distributing mains	4,225,000
The total cost of undertakings will therefore amount to	41,905,000

It was calculated that the annual and avoidable cost to the dwellers in the Metropolis of the present system of coal consumption equalled £9,535,400. If this annual amount was equally divided between the corporation that carried out the project proposed and the London County Council or the consumers, as might be decided, the remaining £4,767,700 would alone enable our interest to be paid on the capital expended. To enable the scheme to be easily accomplished, the shareholders in the existing gas companies might be given the preference in the coalfield gas scheme.

Although the amount required appears to be a very liberal one, it is a mere fraction of the capital that has been expended in the trunk railway lines connecting the Metropolis with the North, and it scarcely bears comparison with the capital that has been rapidly raised in the City for loans to untrustworthy foreign Governments.

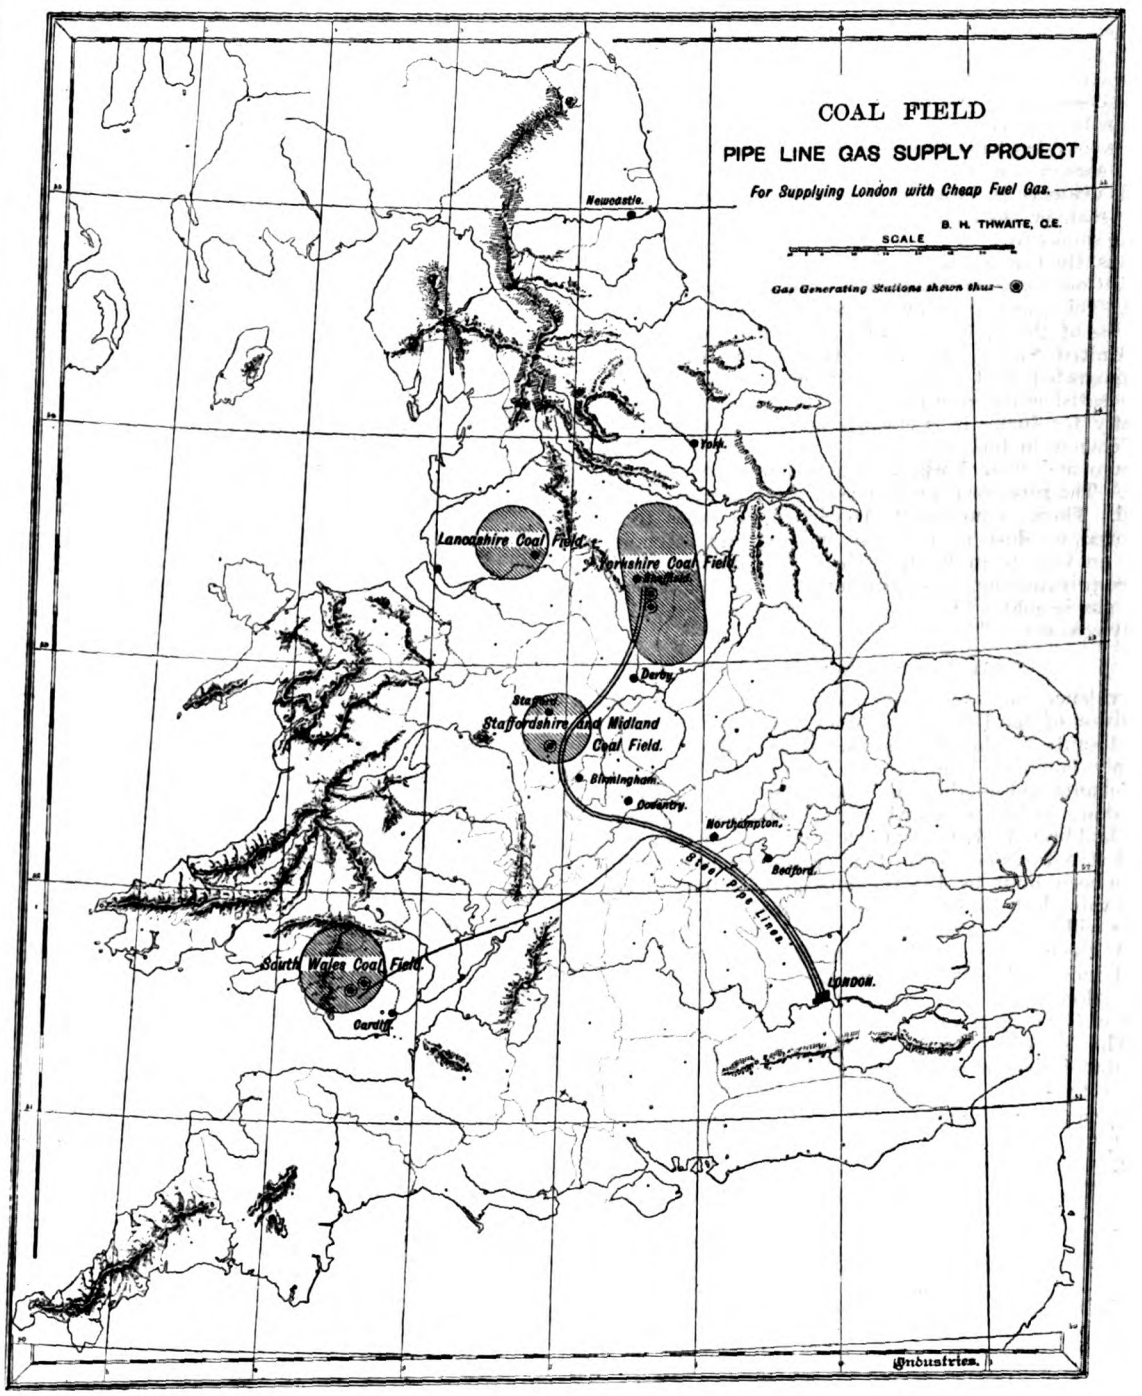
It is a scheme that deserves the serious attention of all those who love London, and of all those who realise the enormous enterprise by which this modern Babylon, this wonder of the world, has been raised stone by stone, inch by inch, until it gathers and rears under its walls a population equal to that of Scotland and of Wales put together.

An Alternative Scheme.

If the project were carried out independently of the existing gas companies, leaving to the latter the distribution of the lighting gas, and as much heating gas as they chose to supply, the expense of the project would be much reduced, as it would not be burdened with the £30,000,000 sterling necessary to buy up all the interests of the existing gas companies.

Besides, this alternative scheme would not interfere with the existing demand for the four to five million tons of Durham seaborne coal—which is principally converted into gas at the London gas works—and the carriage of which by sea is cheaper than by rail.

The cost of this alternative project to deal with 8,000,000 tons of coal, would be made up as follows :—



Yorkshire installation		£3,270,000
Midland and Staffordshire installation		1,670,000
South Wales installation		1,425,000
Distributing system, land	£1,500,000	
Two sets of trunk lines	1,112,000	
Metropolitan distributing lines	1,600,000	
		4,212,500
		£10,577,500

The cost of the project would therefore approach 10¾ millions sterling. When this is compared with the 26 millions expended in London improvements since 1856, and with the 15 millions sterling expended on existing London gas plants and distributing mains, it does not appear such a serious obstacle.

The saving in carriage by rail alone would equal £2,780,000. The value absorbed by merchants, carters, and middlemen may be estimated at £2,200,000. The value of the nitrogenous and hydrocarbon residuals may be taken at £1,975,000. The total saving, therefore, equals £6,955,000.

This annual saving would, therefore, more than equal, in two years from the time of completion, the entire cost of the project.

No doubt a revolutionary project of this character will meet with the usual opposition of vested interests. It is stated that many millions sterling are invested in rolling stock—rail and roadway—for the transmission of the coal, which, when once converted into a gaseous condition, will flow like water from its source of emission from the earth to the place of use, and in its gaseous condition—as proved by the experience of the enviable inhabitants of Pennsylvania—it is most advantageous, whether on hygienic or economic grounds. It enables the maximum heat efficiency of the fuel to be obtained, and in such a manner as to be in harmony with the laws of Nature, and were the scheme once carried out London would be adequately provided with a supply of fuel suitable for generating heat and power, without involving an accompaniment of the black demon, smoke.

APPENDIX.

Since the foregoing pages were written, London has been visited with a fog of almost incomparable density, and for weeks trade and industry have been harassed, and the fog has involved the production of untold misery on thousands of poor people. The shopkeepers in the West End have been great financial losers, the shipping trade and railway and 'bus traffic have been dislocated, and the street casualties have been increased. Altogether the fog has been the cause of misery to an untold number of people, whilst the mortality increase is represented by a death-rate during every week the fog lasted of nearly 300 persons more than the average.

In an article on this, last February, the *Lancet* remarks :—

"In considering these gloomy winter clouds, one primary idea which commonly presents itself is that of smoke. Our tingling eyes and our offended sense of smell alike protest against this contact of carbonaceous matter out of place. Analysis confirms the sensible fact. Surely among so much that is foul, though greatly diluted, there is also the means of mischief. There is no question as to the injury to health, fatal too often, which the fog annually brings."

A famous London correspondent writes as follows :—

"From morning to night many millions of people had to breathe as best they could an atmosphere that seemed to be composed of frozen particles of soot and sulphur. Only those who passed the long hours of the dark days in the midst of the terrible fog can realise the suffering which it brought with it. In the streets, in the omnibuses, in the railway carriages, the people seemed to be positively benumbed by the dreadful visitation. They cowered together in speechless misery. Existence itself was painful. No wrappings could keep out the fog, and many hundreds of people were poisoned by it, as certainly as though they had drunk prussic acid or a solution of arsenic."

Another of the journalistic craft writes :—

"Everybody is railing or swearing at or sighing over the fiendish fog that has kept London in its grip during the last fortnight ; the thick darkness has reached a climax ; the trains as they pass across the bridges are exact representations of Mirzah's vision on the hills above Bagdad as they emerge from a mysterious misty region. The palatial halls of the West End are utterly

Digitized by Google

deserted. In one of the largest and best known drapers shops in the West End the attendants complain that 'business is at a standstill, and the season's trade is practically lost.' The flower, confectionery, and jewellery trades are also great sufferers by the fogs. It drives the tradespeople to depair, and every where one refrain is repeated — 'The fog is disastrous—ruinous.' The three weeks' fog has done more harm to the tradesmen than a season of industrial depression."

This evidence is valuable as showing in a more adequate manner the enormous loss to Londoners entailed by the smoky fog.

"Gas, the Coming King," is the headline of the *Pitsburgh Commoner*, of December 20th, 1890, recently to hand. This paper gives a very interesting account of the progress of the application of gas for fuel purposes in the United States. It states that—"Experience has demonstrated that coal manufactured into gas gives more satisfactory results than when the coal is used directly for fuel. It is cheaper and more convenient. The change in fuel amounts to a revolution in Boston, Chicago, and New York, and bids fair to do so even here. The superior convenience of gas is readily recognised. There is no coal to be carried, no ashes to be removed, no dust, no noise in building and attending fires, no trouble in lighting them. In Boston, Mass., where private companies furnish the gas, especially cheap fuel gas is sold. Every day sees the carting away of many coal stores."

The London Coal Dues.

Evidence has lately been adduced to prove* that the abolition of the London coal dues has not benefited the inhabitants of the Metropolis, but that the dues have simply fallen or been diverted into the pockets of the merchants and middlemen. The value of these dues to London may be realised when it is stated that, including the building of St. Paul's Cathedral, most of the important structures erected in London since the fire of 1666 have been built by the amounts levied as dues on coal. The value lost to London by the abolition of the coal dues will thus be realised.

By the carrying out of the project outlined the London coal dues would not be lost to Londoners. This advantage alone is a strong argument in favour of the carrying out of the project suggested.

The following is a brief summary of the salient advantages that would follow the carrying out of the project:—

1. The saving of the cost of railway carriage.
2. The saving of the cost of cartage.
3. The saving of the middlemen's profits.
4. The recovery of the valuable nitrogenous and hydrocarbon constituents.
5. Avoidance of loss of coal in transit.
6. Reduction of loss of heat value of coal by exposure to the weather.
7. No labour required in clearing away ashes.
8. Prevention of smoke, and with it the obnoxious characteristics of the London fog.

The carrying out of the project would require six years. By that time London would probably be lighted by electricity, so that the city would be transformed from one of the dirtiest to one of the cleanest cities in the universe.

Notes.

THE INSTITUTION OF NAVAL ARCHITECTS.

In order to encourage the preparation of papers for the Institution, the Council of the Institution of Naval Architects has decided to present a gold medal to any member or associate of the Institution, not being a member of Council, who shall at the forthcoming spring meetings read a paper which, in the judgment of the Council, shall be deemed of exceptional merit. It is to be hoped that this arrangement will help to draw some good papers, as we understand the Council has for some time had some difficulty in obtaining the necessary supply. The ordinary dates for the annual meetings will fall on the 18th, 19th, and 20th of March.

RAILWAYS IN PORTUGUESE WEST AFRICA.

According to an official report the three first sections of railway, from Loanda to Cassoneca, of 88 miles, have been completed and are in actual use. Including the termini there are in all nine stations, and the average rate of running is 12 miles an hour. According to the report, the other sections, which are ultimately intended to join Loanda with the Zambesi, are being actively pushed forward, hundreds of labourers being at work upon them, under the superintendence of Portuguese engineers. Of the fourth section, 25 miles, the embankments and cuttings have been completed. The work on the fifth section of 25 miles is being carried out at twelve different parts by an army of workmen. Work has also been begun on the sixth and seventh sections, and if all this zeal is maintained without flagging there ought by the end of the year to be 180 miles of railway in running order from Loanda towards the interior. There are, we understand, about 3,000 natives employed on the line.

* Report of the Corporation of London Corn, Coal, and Finance Committee, December, 1890.

GENEROUS ACTION OF A JAPANESE SHIPPING COMPANY.

As an argument for Mr. Plimsoll, we cite the following from the *Japan Gazette*:—"The Directors of the Nippon Yusen Kaisha, the largest shipping firm in Japan, have acted very generously towards Mrs. Frahm, widow of the captain, and the other relatives of those foreigners who went down with the steamer 'Musashi-maru.' Mrs. Frahm has been voted the sum of $2,000, and the rest varying amounts." This, the *Japan Gazette* remarks, "does not bring back the dead, but it is a recognition that may in some measure soften sorrow and an instance of substantial and voluntary generosity."

THE MELBOURNE CENTENNIAL EXHIBITION.

The balance sheet of this Exhibition has at last been published. The total receipts from all sources (except, of course, the Government) were £100,241 16s., and the gross cost was £338,026 10s. 8d. Therefore the bill the Victorian Government had to pay amounted to £237,784 14s. 8d. The total cost of the temporary annexes was £125,177 16s. 7d., and they realised only £14,886 10s. 1d. More than £46,000 was spent in alterations and decorations to the permanent buildings. The electric light cost £77,000, and the plant sold realised about £21,000, while gas and gas fittings cost over £8,000. The orchestra and chorus cost over £28,000, and the receipts for admission were just over £9,000. Medals and certificates cost under £7,000.

THE "ELECTROCUTION" OF INSECTS.

A kind of moth or butterfly is said to have become so troublesome and destructive in a forest in Bavaria, that it was necessary to destroy it. Children were employed to collect the caterpillars, and were paid so much per bucketful. This was found expensive and ineffective, so enormous fly papers were tried. These also had no appreciable result. Finally, it is said, that an electric search light in connection with a blowing fan was designed. The insects are attracted by the light and fly near the lantern; they are then drawn into the suction pipe by the air draught, and carried to a sort of mill, which mixes them with a little flour. The resulting compound is then used, we understand, for poultry food.

THE GERMAN SPIRIT TRADE.

Potato spirit forms an important article of German commerce, but the trade is not as flourishing as it used to be. An official report from Dantzig states that the trade in spirits is much hampered by the duty law of 1887, and a general shrinkage of business has taken place since that year. The potato crop in the province of West Prussia in 1888 was a bad one, causing a smaller production of potato spirit in 1889 than in the preceding year. The foreign markets opened unfavourably in the year, and Dantzig's best customer, Spain, is deserting it, the export to that country in 1889 being only about a fifth of what it was four years ago. The new spirit duties imposed in Spain benefited the home production in that country, but did not fill the Spanish treasury, as they were expected to do. After the understanding come to by the German and Spanish Governments with regard to spirits, the export to Spain revived again, but speculative transactions have led to loss.

DOCKING ACCOMMODATION AT NAGASAKI.

The want of good docking accommodation in China and Japan has hitherto been one of the greatest difficulties the owners of large steamers trading to those countries have had to contend with. Now, however, we learn that good accommodation is to be had at Nagasaki, Japan, in the docks belonging to the Mitsui Bishi Company. Recently the British steamer "Afghan" was taken into the docks and scraped, dried by means of torches, given two coats of anti-fouling paint, and made ready for floating out again within ten hours of entering the dock gate. In order to form some idea of the amount of work involved in these operations, it may be mentioned that the "Afghan" is 320ft. in length, and of 2,206 tons gross register. On coming out of dock she commenced to take in Takushima coal, and ten hours afterwards she was ready for sea with a full cargo of 2,818 tons on board, bound for Sydney. For vessels engaged in such a trade accommodation of this kind is of the greatest importance.

IMPROVED POSTAL ARRANGEMENTS.

With the New Year commenced a large reduction in the postal rate to India and the colonies, a boon which will be of great advantage to our industry and commerce. In future a half-ounce letter will be carried for twopence halfpenny between this country and all the British possessions in India and the Eastern group of colonies—Australia, from New South Wales and Victoria down to Fiji and New Guinea, South Africa, the West Indies, and the West Coast of Africa. The relief extends to post-cards as well as letters so far as the Australian colonies are concerned, the rate being twopence instead of threepence, although it is difficult to see why the area for these should be restricted. Greater uniformity and a reduction of charges have also been introduced in the case of unstamped or insufficiently stamped letters. It is impossible to say how far the changes will affect the revenue of the Post Office, but that is sufficiently flourishing to allow of some reduction. It is probable, however, that the increase in the number of letters sent will compensate for the reduction of charges.

MANUFACTURE OF OXYGEN AND HYDROGEN BY ELECTROLYSIS.

At a recent meeting of the Société de Physique Commandant Renard made a most interesting communication relative to the electrolytic production of oxygen and hydrogen for commercial use. Allowing a volt and a half as necessary, and allowing even an efficiency of 50 per cent., 144 c.c. of hydrogen can be produced per watt hour. This means 6,930 watt hours per cubic metre at 3d. per 1,000 watt hours, which makes the cost 1s. 9d. per cubic metre, or, roughly, 50s. per 1,000 cubic feet. This estimate assumes the oxygen to be waste. The two gases come out at 33s. per 1,000 cubic feet. All that is necessary to make the gases on a large scale is to use a large dynamo and large vats. No further experiment is necessary. M. Renard proposes to use caustic soda as electrolyte, as this admits of iron electrodes. Dilute acid would need platinum or lead plates, and lead plates take a high electromotive force to decompose water. Each plate is encased in a porous gas collector, so that the gases are kept separate. M. Renard has already used hydrogen prepared in this way for inflating balloons.

ELECTROSTATIC MEASURING INSTRUMENTS.

There would seem to be some kind of prejudice against the use of electrostatic measuring instruments. Generally, in an alternating current station, we find the high-pressure leads connected to transformers reducing to 100 volts or so, and a hot wire voltmeter employed to read by. The transformer takes, say, 30 watts, probably more, and the voltmeter another 30. This means 500 kilowatt hours per annum wasted. At 2½d. this comes to £5 a year, which is the interest on from £50 to £100. A laboratory electrometer was used in electric engineering by Joubert in 1881, and others have been used occasionally since by Professors Ayrton and Perry, Ryan and Monnier. Sir William Thomson has, however, introduced a number of electrostatic instruments, reading from 100 volts upwards, and engineers who use them do not revert to electromagnetic or hot wire voltmeters. Electrostatic instruments not only take no power, but have no temperature errors, and do not need corrections for frequency, and no doubt they will eventually be cheaper than other forms. They cannot well be used as ammeters, but it is rumoured—with what foundation we do not know—that Dr. Fleming will soon bring out an electrometer wattmeter. Of course, as shown by Professors Fitzgerald, Ayrton, and Perry, a quadrant electrometer can be used to measure power, but unless the fall of potential over the shunt resistance in the current circuit is small, difficulties arise. Probably the electrostatic wattmeter of the future will have a split needle.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

1st January, 1891.

1. Goad & Redman ..... Appliance for use in dyeing, &c., clothes.
3. Wood, W. ..... Apparatus for removing quarry "barings."
4. Pollock, J. F. M. ..... Hydraulic and other high-pressure valves.
6. Moore, J. T. ..... Variable speed gears.
9. Gehrling, J. F. C. ..... Machines for setting tubular rivets.
19. Syer, M. ..... Waste-preventing valve.
21. Reddaway, F. ..... Apparatus for stretching machine belting.
25. Knowles & Stephens ... Snow ploughs.
34. Robinson, T. N. ..... Wood-working machinery.
36. Pankhurst, J. F. ..... Steam ash ejectors. (16th June, 1890.)
42. Thom, J. ..... Steam boilers.
45. Dodd, W. ..... Boat-lowering apparatus.
46. Hornsteiner, R. ..... Cramp keys for securing wheels, pulleys, &c.
57. Granger & Dalby ..... Lace machines.
64. Reed, Smelt, & Ainley... Water taps.

2nd January, 1891.

69. Strudwick, H. ..... Railway fouling bar.
71. Parsons, C. A. ..... Steam boilers.
73. McFerran & Pirrie ..... Ring and traveller frames for spinning wet yarns.
74. Verreker & Yeates..... Starting gear for tramcars.
75. Letalle, L. ..... Loom for the manufacture of chenille.
84. Mayer, C. G. ..... Refrigerating apparatus.
85. Mayer, C. G. ..... Gas pumps.
108. Pinkney, C. W. ..... Hydrocarbon engines.

3rd January, 1891.

110. Carling, J. ..... Gas engines.
112. Williams, H. (of the Illuminating, Heating, and Power Gas Company, Ld.)..... Exhausters and blowers for gas or air.
113. Fey, W. A. ..... Lifting appliances.
120. Martin, J. T. ..... Tools for punching and cutting.
131. Pullman & Smith ..... Apparatus for treating hides or skins.
136. Bayly, J. P. ..... Pulley (*Magers*).
142. Bayly, J. P. ..... Car coupling (*Fish & Cole*).
148. Bayly, J. P. ..... Wood-working machine (*Burrell*).
147. Bayly, J. P. ..... Rotary engine (*Worley & Davis*).
148. Bayly, J. P. ..... Rivet-making machine (*Danks*).
151. Bayly, J. P. ..... Apparatus for cleaning boiler flues (*Smith*).
164. Horn, W. W. ..... Air brakes (*Guillemet*).
167. Popp, V. ..... Air pressure engines.

ELECTRICITY.

1st January, 1891.

12. Bennett & Hides ..... Terminals for telephones, &c.
40. Hookham, G. ..... Electricity meters.
49. Wensky, W. ..... Producing constant electric currents.

2nd January, 1891.

96. Bardot, E. ..... Printing telegraphic apparatus.
100. Johnson & Phillips ..... Suspension insulators for electrical conductors.
105. Haselwander, F. ..... Lightning arresters for electric conductors.

3rd January, 1891.

128. Lee, J. L. ..... Automatically regulating electric currents.

CHEMISTRY.

1st January, 1891.

37. Alzugaray, J. B. ..... Fluxes for use in treating metals, ores, &c.
44. Fewson, H. ..... Treatment of sewage.
59. Wilkinson, H. ..... Purification of oils and fats.

2nd January, 1891.

86. Bedford, C. S. ..... Process of dyeing on cotton.

MISCELLANEOUS.

1st January, 1891.

2. Lapage & Bruce ..... Steering compass.
5. Shapley, F. ..... Apparatus for mitigating the force of railway collisions.
15. Setten & Durward ..... Manufacture of compasses or dividers.
23. Spong, J. O. ..... Apparatus for obtaining chromatic illumination from gas.
24. McFerrand & Pirrie ... Winding wet spun yarns of flax, &c.
65. Jaques, J. ..... Ships' propellers.

3rd January, 1891.

109. Freemantle, G. ..... Pipes and tubes.
117. Noton, W. ..... Bolsters, bushes, and steps of ring spindles.
126. Gorse, F. W. ..... Split cotters or lynch pins.
157. Faber & Joseph ..... Railway chairs.
158. Faber & Joseph ..... Railway chair combined with fish plates.
165. Sailler, A. ..... Manufacture of metal plates hardened at one side.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1890.

179. Styles.
558. Wheeler.
1146. Drake & Gorham.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Jacquard Machines.—*W. Hardaker, Great Horton, Bradford.*—This improvement consists in substituting for the ordinary "neck cord" a single or double wire for attaching the harness to the upright hooks of the machine. This wire has a loop formed at one end, which is passed over the bottom hook of the upright wire of the machine. The wire is then passed through the bottom board in the usual manner, and the lower end, on which a second loop is formed, is connected to the harness. It will thus be seen that by the use of the above arrangement the friction in the bottom board is much less than with the usual "neck cord," there is less wear and tear, and as the loop of the wire is closed on the neck of the harness, there is no risk of their catching each other. Claims: The use of a wire in place of the ordinary "neck cord" usually employed in jacquard machines in the manner and for the purpose set forth.—No. 2072. February 8th, 1890. 4*d*.

Process of Galvanising Tubes and Bars.—*T. L. Thomas & J. B. Hillman, both of Princes End, near Tipton, Staffordshire.*—According to this invention tubes, rods, and the like, after being immersed in the liquid zinc, are withdrawn and as quickly as possible passed between a pair of asbestos dies, so cleaning off all the superfluous metal and forming a smooth surface. The articles are then immediately dipped into cold water. The asbestos dies are fixed respectively to an upper and lower wood block, the latter of which is fixed to a frame or bracket, which is itself fixed to one end of the galvanising bath, and the former is carried by a lever or vertical slide, by which it can be raised or lowered to suit the diameter of the rod or tube. The dies are formed so as to, between them, embrace the entire circumference of the tube or bar, and the one die preferably overlaps the other to some extent at the base, when the dies are closed up, so as to avoid a gap at the joint between them. Six claims are made, embracing the process as described, together with the apparatus and various modifications thereof.—No. 8572. June 3rd, 1890. 8*d*.

Looms.—*J. & R. Lindsay, Dundee, Forfar, N.B.*—This patent has reference principally to the let-off mechanism of looms for weaving. Fig. 1 is a sectional plan, and Fig. 2 a sectional elevation, of that part of a loom showing the modifications according to this invention. A lever A, the upper end B of which touches the warps on the beam, is kept in contact with the warps by a weight C. This lever is fast on a rocking shaft D, as also is a toothed sector E which gears with a pinion F on a shaft G carrying at each end a specially shaped cam H which acts on a link I jointed to a radius lever J and connected to a rod K arranged to transmit the pressure from a weighted lever L to the

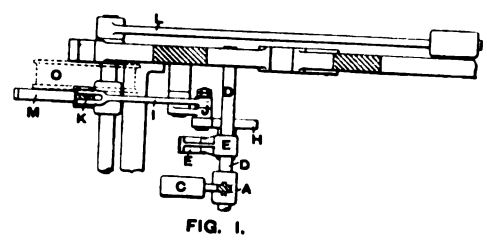

FIG. 1.

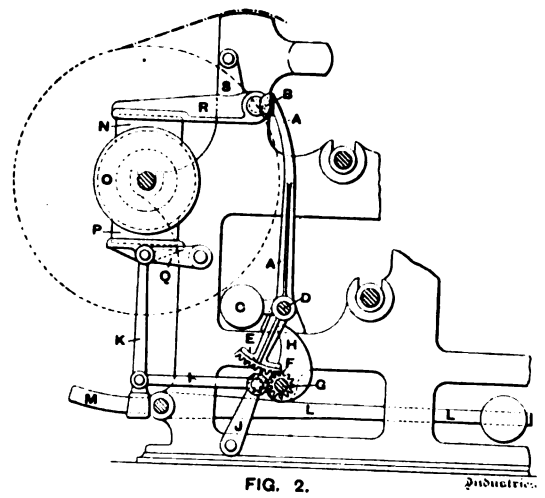

FIG. 2.

frictional appliance. The action of the cam H moves the rod K gradually further from the fulcrum of the lever L as the diameter of the warps on the beam diminishes, and thereby causes the effective pressure on the frictional appliance to be diminished in a manner to keep the tension of the warps practically uniform. The rod K has its lower end fitted to slide upon a curved arm M fixed on the rocking shaft carrying also the weighted lever L. An improved frictional appliance is used, consisting of a fixed brake block N, arranged with an elastic connection, above each friction pulley O, combined with a movable brake block P below, the latter being pressed upwards by L through arm M and rod K, which last has its upper end jointed to the brake block P. The upper end of the rod K is also connected to the framing by a radius link Q. The block N is held by an arm R centred on a stud fixed in the framing to allow of its being raised when placing or removing a warp beam, the arm being locked in position by means of a cod-piece S. To turn back the warp beam, the levers M being relieved, the blocks, beam, and pulleys O descend clear of the blocks N, and the beam rests in end journals in the bracket bearings of the loom framing so that it can be easily turned. Three claims are made, embracing the apparatus as described, with modifications.—No. 1916. February 5th, 1890. 8*d*.

Tubular Shafting.—*G. C. Marks, Birmingham.* (*G. H. Ogilvy, New York, U.S.A.*)—The process of forming tubular shafts embraced by this invention is as follows:—A bar of iron or steel of suitable length, breadth, and thickness is formed, by rolling or otherwise, into a half tube. The edges are then planed or machined until they make a level surface with each other, and at certain intervals along each edge are formed recesses by cutting away the metal below the level surface of the tube edges, so that these edges, when completed, consist of a series of elevated and depressed surfaces. A second tube is then formed in a similar manner, and the two placed together, the depressions of one half receiving the elevated portions of the other. The whole is then temporarily secured together by suitable collars placed over them, and after being turned other rings or collars are shrunk on. Claims: (1) The construction of hollow circular shafting substantially as described; (2) the construction of circular shafting, with bearings or journals shrunk upon same. —No. 1911. February 5th, 1890. 8*d*.

Digitized by Google

WATER GAUGES.—*R. Klinger, Vienna, Austria.*—The gauge constructed according to this invention consists of a suitable metal plate having centrally along its length a U-shaped groove. Clamped to the front of this recessed plate is a second plate having a long narrow slot formed centrally in it, which slot is covered by a suitable plate of glass pressed by means of the plate against the flanges or edges of the U-shaped plate, so closing the U-groove, from each end of which the usual pipes connecting the gauge to the boiler project. That part of the back of the glass which covers the U-groove has facets formed in it causing the reflection of the rays of light when only steam is in the U-groove. The rays of light, however, falling on the glass, will penetrate through that part of the gauge where water, which has a greater refractory power, takes the place of the less refractive steam. Claims: In gauge glasses the arrangement of suitable facets, adapted to allow the rays of light to penetrate that part only of the glass which contains liquid to make the colour of the background visible, so that that part of the gauge not containing or in contact with the liquid may have the rays of light entirely or partially reflected on the facets, presenting a bright transparent surface substantially as and for the purpose described.—No. 18273. November 13th, 1890. 6*d.*

GAS ENGINES.—*A. E. Tavernier & E. Casper, both of London.*—This invention has for its object a method of cooling the cylinders and pistons of gas and other engines operated by an explosive mixture. In the annexed illustration is shown a vertical section of a cylinder and piston constructed to embrace the object of this invention. The cylinder A has formed on its outer periphery ribs B, which strengthen the cylinder and at the same time provide a greater cooling surface to be acted upon by the water in the annular space formed by the flanges at each end of A and the cover C formed in halves and clamped together as shown at D (Fig. 2). E is the explosion chamber fixed to A by screws F. G is the piston, which is made hollow as shown, and H are the flanges therein to increase the cooling surface. I is the hollow piston-rod communicating at one end with the interior of the piston by the orifice J and provided at the other end with an arm K, having nozzles L and M, to which flexible tubes or the like for the circulation of the cooling liquid are attached. The arm K is provided with a channel W communicating at one end

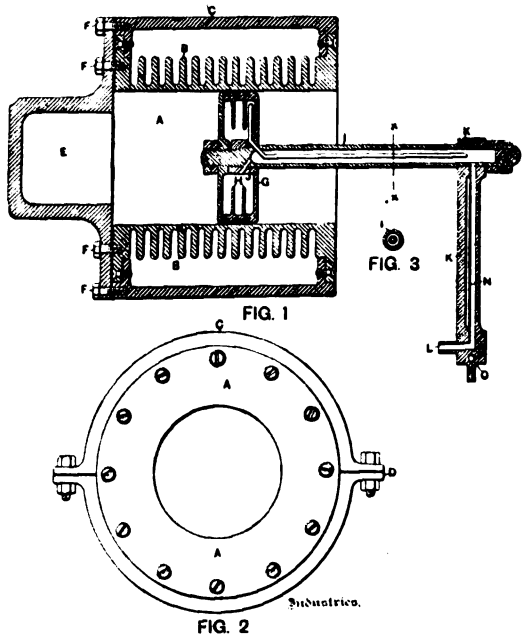

FIG. 1

FIG. 3

FIG. 2

with the interior of the rod I and terminating at the other end in the nozzle L, so that the cooling liquid can pass through the said channel and the rod I into the piston G by the orifice J. The return current passes through a tube arranged in the rod I and connected by a channel O in the arm K behind the channel N to the nozzle M. Claims: (1) An engine cylinder having formed upon its exterior a series of flanges affording a large area of cooling surface; (2) an engine cylinder having formed upon its exterior a series of flanges and surrounded by a jacket substantially as described; (3) an engine piston provided with means whereby a cooling fluid may be passed therethrough; (4) an engine piston having a series of internal flanges, and provided with means for causing a current of cooling fluid therethrough substantially as and for the purpose described.—No. 1586. January 29th, 1890. 8*d.*

STONE SAWING MACHINERY.—*S. Dearden & W. Dearden, both of Nelson, Lancashire.*—For the above purpose the inventors construct a suitable framework of wood or other material. At the top of this framework is mounted a crane for raising and lowering the saw frame, which is suspended at each corner from radius rods attached to chains passing over suitable pulleys and operated by the crane. Opposite one end of this framework is a horizontal driving shaft running in a framework of its own, and having at each end a crank disc, the cranks of which are connected by means of connecting rods to suitable sliding bars sliding in guide-ways formed in a stretcher fixed to the uprights of the framework. To the outer extremities of these slide-bars are fixed vertical heads, which are connected to the saw-frame by means of suitable slide brackets and links. Suitable tension rods are connected to the ends of the vertical reciprocating heads and the slide-bars to render the heads more rigid. Claims: (1) In combination with a horizontal saw-frame, reciprocating heads, horizontal slide-bars operating together with crank and crank-arm device as described; (2) in combination with a horizontal saw-frame, reciprocating heads, and horizontal bars radiating at the lower extremity of radius arm and actuated from the crank and crank-arm device as described; (3) in combination with a saw-frame, a reciprocating head actuated from a steam ram.—No. 2021. February 7th, 1890. 8*d.*

APPARATUS FOR THE PRODUCTION OF CARBONIC OXIDE GAS.—*T. Williams, London.*—In the annexed illustrations Fig. 1 is an elevation and Fig. 2 a plan of a complete apparatus for the above purpose, and consisting of a working cylinder A operating a gas supply pump B and a vacuum pump C. The pump B supplies impure gases from the source of supply to three tanks D, provided with a cupreous chloride solution through perforated openings in pipe E. This solution absorbs the carbonic oxide gas, and they then pass to a second set of tanks D^1. From D^1 the unabsorbed gases escape by pipe F, and the solution charged with

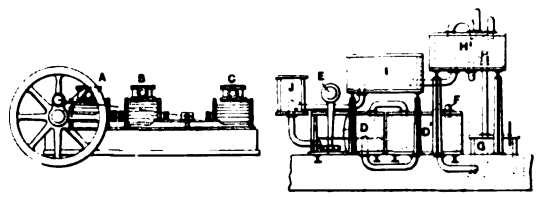

FIG. 1

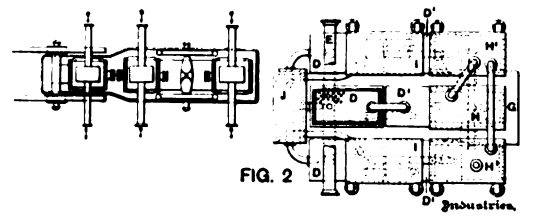

FIG. 2

carbonic oxide flows into a storage tank G. From G, by means of the vacuum pump C, the solution is drawn up into a tank H, and is distributed equally into two other tanks H^1, the pure carbonic oxide gas being freed by the action of the vacuum therein and escaping through the vacuum pump. From H^1 the cupreous chloride solution passes to two other tanks I, and, passing through a cooling tank J, returns by gravity to the tanks D, in which it again commences its work of absorption of carbonic oxide gas from the gases. Claims: The improved means and appliance for the production of pure carbonic oxide gas from coal, coke, or like fuel, the arrangement of tanks, pipes, and machinery constituting a plant, shown in the above illustrations, the parts operating in the manner and for the purposes set forth.—No. 19096. November 27th, 1889. 8*d.*

STARTING MECHANISM FOR TRAMCARS.—*J. Hewins & C. Hardy, both of Great Grimsby.*—The invention consists in machinery for stopping and starting tramcars, to be used instead of tyre or other brakes. On each of the two car axles is a friction wheel adapted to be brought into respective engagement with one of two corresponding friction wheels on shafts journalled in the respective ends of a swinging frame. On each of these shafts are also four pulleys, two geared by two cross chains with respective pulleys on the other shaft, and two having connected to them chains adapted to be wound thereon by action of the friction wheels when the latter are in engagement respectively with one or other axle friction wheel, and so bring into tension springs attached to the other ends of said chains. Lever gear is provided to be operated by the driver to move the frame, so as to bring the friction wheels into respective engagement. The springs, tensioned by the action of the friction wheel of one axle, may thus be made to operate for assistance in starting the car by engagement of the friction wheel on the other axle. Claims: The arrangement substantially as described.—No. 549. January 11th, 1890. 6*d.*

PRINTING MACHINES.—*A. Paton, Leeds, Yorkshire.*—The invention relates to the application of ink-distributing cylinders instead of inking tables in lithographic and letterpress printing machines. In the annexed illustrations, Fig. 1 shows the spring frame with the cam for raising and lowering it, in combination with the inking rollers and ink-distributing cylinders; Fig. 2 is a partial end view of the same, and Fig. 3 details of an apparatus for this purpose. A are the ink-distributing cylinders, having a continuous revolving motion and a transverse motion. B are the

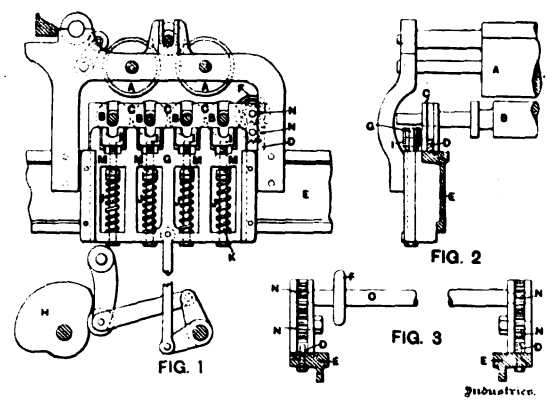

FIG. 1

FIG. 2

FIG. 3

inking rollers in the ordinary bracket C, which has the new method of removing it out of position in order to clean or change the rollers, namely, a rack D, which is placed inside the bottom of the roller bracket the whole length and fastened to E, the side frame of the machine. Two pinions geared into the rack and set inside the end of the roller bracket over the rack are used, so that by turning the hand-wheel F the brackets with the rollers can be removed from underneath the ink-distributing cylinders. G is the rising and falling frame, actuated by the cam H, so that when the frame is raised to the full extent the half-bearings I hold the inking rollers up against the ink-distributing cylinders, having the elasticity of the springs J coiled round the spindles K, which move loose in the frame, being screwed into the half-bearings I, and having adjustable nuts M to give more or less pressure to the inking rollers. Fig. 2 shows the rising and falling frame G as outside the ordinary inking roller bracket C. In Fig. 3 N are the pinions geared together and into the rack. The top pinions are fixed on to the hand wheel shaft O. It is evident that by turning this hand wheel the brackets will be carried along the rack. Claims: (1) The frame G with springs or any elastic matter, or balance weights as the substitute for springs, in combination with the ordinary inking roller brackets and ink-distributing cylinders as described; (2) the frame G acting as a roller bracket and rising frame in one; (3) in combination with the frame G the application of the rack inside, and under the ordinary roller brackets, with pinion or pinions to slide the brackets over the top of the rack as shown in Fig. 3.—No. 20701. December 24th, 1889. 6*d.*

APPARATUS FOR COATING HOOP IRON WITH TIN.—*T. H. Johns, London.*—For the above purpose the inventor arranges a flat perforated tube in a long trough through which the hoop iron is passed, the tin or other metal being kept in a molten state in the trough. The mouth of the flat tube is slightly funnel-shaped for the easy entrance of the hoop iron from the feed rollers, and the outlet of the tube is just below the level of the molten metal, the grease being above. Just outside the delivery end of the trough another tube, having a slot in it, is arranged as a scraper to act upon and scrape both sides of the hoop iron as it emerges from the trough and is carried forward, by means of two pairs of V-shaped and revolving rollers, in housings, in which they can be adjusted by means of set screws. Claims: (1) The apparatus as described, for enabling iron hooping bands and other widths or lengths to be coated, scraped, and drawn from the scrapers without the flat surface being touched after leaving the scrapers; (2) the system of coating hoop and like iron in lengths, consisting in passing it through a tube or guide in a bath of molten metal, then between scrapers, and finally between rollers, which do not touch the flat surfaces during the drawing forward and cooling processes, substantially as described.—No. 1522. January 28th, 1890. 6*d.*

SHIPS' DAVITS.—*W. H. Penligen, Hull.*—The object of the invention is to provide davits by means of which the ship's boats may be more readily and easily lowered. The davit constructed according to this invention consists of a suitable standard carrying a horizontal shaft mounted in suitable bearings, and upon which turns a semi-circular frame, partially toothed upon its circular and lowermost edge. This frame has an upward extension or bracket, to which, as well as to a portion of its lower circular edge, is riveted the davit proper, this davit being curved at the top in the usual manner and braced thereat by means of a diagonal bar. The standard carrying the horizontal shaft carries upon a lateral extension, as well as on its centre, the axis of a worm wheel gearing with the teeth of the semi-circular frame, and actuated by means of a suitable crank handle. Suitable tackle falls and sheave blocks are provided to hoist and lower the boat. Upon the upper part of the semi-circular frame chocks are formed in which the boat may be set, the outer sides of the chocks being so arranged that when it is desired to release the boat these sides may be caused to fall flat, so freeing that side of the boat. Claims: (1) The improved ships' davit arranged and constructed substantially as described; (2) the mechanism for turning the boat overboard without hoisting, consisting of a toothed semi-circular frame gearing with a pinion actuated by a handle in combination with a standard; (3) in ships' davits holding the boat between a fixed and movable chock, the latter being actuated by a crank lever pivoted on the shaft upon which the davit turns.—No. 6822. May 2nd, 1890. 6*d.*

AUTOMATIC LUBRICATOR.—*J. McDonell, Limerick, Ireland.*—The lubricator constructed according to this invention is for use with semi-solid lubricants, and consists of a cylinder of suitable dimensions provided on its inner circumference with two spiral grooves, forming a double-threaded screw, and within this cylinder is arranged a diaphragm, the periphery of which is provided with spiral projections, corresponding with and engaging in the spiral grooves in the cylinder. On the upper end of the cylinder is arranged a suitable box containing a coil spring, one end of which is secured to the box and the other end to a central spindle. The latter extends through the top of the box, and is fitted on its outer extremity with a lever handle, while its inner end, passing through the bottom of the box, is connected with the diaphragm by means of a hinged rod, so that, as the spindle is rotated by the spring, the diaphragm will also be rotated, and so, following the spiral grooves in the cylinder, caused to descend and force the lubricant out of a central hole in the bottom of the cylinder. The bottom end of the cylinder is fitted with a movable cover for inserting the lubricating material; this cover also forms a shank for fixing the apparatus in position. Claims: The use and application of an apparatus for lubricating purposes, constructed, arranged, and operated in the manner described.—No. 49. January 2nd, 1890. 6*d.*

PILE-DRIVING MACHINERY.—*H. C. Lobnitz, Slip Dock, Renfrew, Renfrewshire, N.B.*—The object of the invention is to provide a reliable device for engaging and disengaging the rams or strikers for pile driving, rock cutting, and similar machinery. For this purpose a weight, externally of a rectangular or other suitable shape, is used. This weight is made with a cavity at its lower end, the cavity having a wide bottom mouth and inclined sides converging to an upper narrow part so that when the weight descends the inclined sides of its bottom cavity causes it and the head of the ram to assume proper and concentric positions relatively to each other. A deep slot is formed across the top of the weight and in it is placed a lever-hook centred on a pin fixed across the slot and passing through the sides of the weight. Embracing this pin at each side of the lever is the bridle by means of which the weight is raised. The straight part of the lever hook extends out horizontally, when the opposite or hooked part is engaged with the bridle of the ram or striker, and an eye is formed in the end thereof for the attachment of a rope for operating the hook. The hook of the lever is made with a tail inclining downwards, and works in a continuation of the slot in the weight, and its end encounters a part at the bottom of the slot and acts as a stop to limit the inward movement of the hooked part of the lever. A spring is applied to the horizontal part of the hooked lever to tend to keep the lever hook in the closed position. When the weight descends the inclined inner sides of the tail formed on the hook encounters the strap on the ram or strikers, and the action of the strap causes the tail or the hook to be pressed outwards and the top of the strap on the ram

Digitized by Google

enters upon the hooked part of the hooked lever. As soon as this takes place the spring causes the lever hook to close again, and the engagement is thereby affected. Claims: Hooking or disengaging mechanism for rock cutting, pile driving, and analogous purposes, such mechanism having, in combination with a lever hook, a spring, or counter-weight to close same, an inclined tail formed on the lever hook for opening it, and a weight to which the lever hook is jointed and which is made with an incline-sided cavity, the parts operating together as and for the purpose set forth.—No. 17978. November 8th, 1890. 6*d.*

PRINTING MACHINERY.—*A. Paton, Leeds.*—The invention relates to the shortening of lithographic or letterpress printing machines by the application of a smaller cylinder than hitherto used, on to which the sheet is fed. Grippers are used for this purpose which bite the sheet out independently of the cylinder, the grippers standing out almost in a straight line from the centre of the cylinder and biting the sheet there. These grippers are opened and closed by a segment of a wheel toothed and fixed on the end of the gripper shaft, and geared into a larger segment working on the end of the cylinder, which has a gripper-pulley on it to run on a path which is raised or lowered at the proper times by a cam or eccentric, thereby opening and shutting the grippers. As the cylinder is coming to a stop the grippers are made to stand out to a position almost in a line from the centre of the cylinder, the grippers being apart so as to receive the sheet to be printed. The top gripper then closes, and the grippers holding the sheet are, as the cylinder revolves, gradually brought closer to the cylinder until they touch same at the top. Claims: (1) The method of feeding a sheet on to the side of a printing cylinder horizontally with its axis, with a double gripper standing out of the cylinder and biting the sheet there clear of the cylinder as described; (2) the combination of a path-bar with two segments and a cam as described; (3) the application of springs to the double grippers to hold them together while biting the sheet, and a tail-piece to keep the grippers apart while the sheet is being fed.—No. 20683. December 23rd, 1889. 6*d.*

MINING MACHINES.—*W. B. Brain & F. Baker, both of St. Kilda, near Melbourne, & A. J. Arnot, Melbourne, Victoria, Australia.*—The invention consists principally in the employment of a number of elastic bands or springs, as connections between a reciprocating collar, to which the primary motion is given, and the spindle of a percussive drill spindle to prevent undue shocks to the machine. In the annexed illustrations Fig. 1 is a vertical section, and Fig. 2 a plan of a mining machine so fitted. The

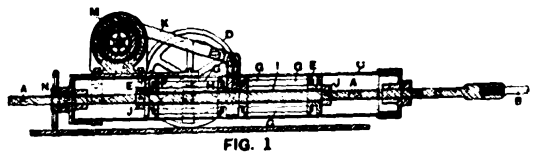

FIG. 1

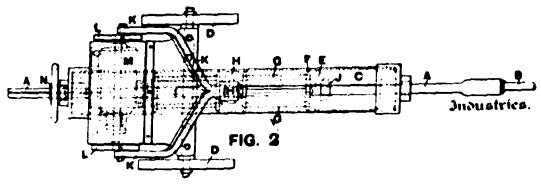

FIG. 2

spindle A carrying the mining tool B is mounted centrally in a bearing in each end of a tube C carried by two wheels D. Fixed at a suitable distance apart upon a tube I fitted on A are two collars E, having radial T lugs F, around which pass elastic bands G, whose opposite ends are secured to similar T lugs on a collar H sliding loosely upon the tube I. At each end of I are collars J fixed to A. The collar H has an upwardly projecting arm H^1 projecting through C and connected by a forked rod K to crank discs L on each end of an electric motor M fixed to C and suitable framework carried by the wheels D. The spindle A can be revolved so as to cause the operating tool B to cut a circular hole by means of a wheel N carrying a suitable feather which slides in a longitudinal slot in A. From the above it will be seen that the motive power from M is transmitted through the elastic bands G to the spindle A, so preventing shocks. Claims: (1) In a mining machine the combination with a reciprocating drill spindle of a collar adapted to slide freely to and fro upon such spindle, together with a number of elastic springs connecting said sliding collar with a pair of collars secured upon the spindle in such a manner that the latter is free to turn in said collars, whilst at the same time it is prevented from sliding longitudinally through them, for the purpose described; (2) in a mining machine the combination of a cylinder, through which can slide the spindle of a reciprocating drill with an electromotor mounted upon said cylinder in such a manner as that the centre of inertia of said motor is immediately over the axial line of the drill as described.—No. 12998. August 19th, 1890. 6*d.*

PORTABLE DRILLING MACHINES.—*W. Settle, Darcy Lever, near Bolton.*—The object of the present invention is to construct a portable percussive drill for boring or "holeing" in mines. The apparatus consists of an electromotor of suitable power upon the shaft of which is fixed a cam or tappet-wheel, which works against a projection upon a rod sliding in suitable bearings in a cylindrical casing and carrying at its outer end the drilling or "holeing" tool. Between one end of this casing and an enlargement on the sliding rod is a spiral spring, which, as the rod is raised, is compressed, and when the rod is released forces same forward, so causing it to act percussively. A handle is fixed to the upper end of the sliding rod so that the latter can be revolved. The cylindrical casing is carried and fed forward in the following manner:—A suitable iron framework is clamped to a horizontal shaft, carried in any suitable manner. Running in bearings in this framework is a vertical screwed rod which can be revolved by means of a worm-wheel fixed to one end of it, and into which gears a worm, actuated by means of an ordinary crank-handle running in a bearing in a bracket fixed to the framework. An internally screwed lug projecting from the cylinder embraces this screwed rod, so that by revolving the latter, the cylinder, together with its sliding rod, can be fed forward as the hole is cut. Four claims are made.—No. 1264. January 24th, 1890. 8*d.*

ELECTRICITY.

FIRE INDICATOR.—*T. R. Douse, London.*—Fig. 1 is a part sectional elevation, and Fig. 2 a general view of a fire indicator constructed according to this invention. A metal ring A fixed to the ceiling of the room in which the indicator is placed carries an insulating ring B, in which are placed the two binding screws C C^1. The screw C is electrically connected with a screw D fixed in A, and projecting downwards in B until nearly in contact with a concentrically corrugated metallic diaphragm E held between the end of B and a metal bridge F. Carried by means of a screw G passing through the lower central part of F is a hermetically closed metallic box composed of two thin concentrically corrugated discs H, connected at their outer peripheries by band

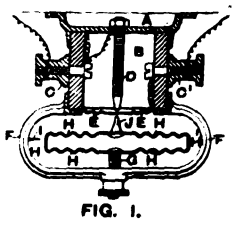

FIG. 1.

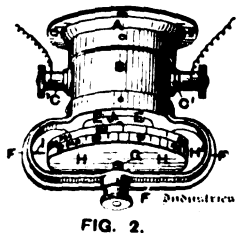

FIG. 2.

H^1. In the centre of the upper disc H is a point J, which can be brought near to or further from E by revolving the box H, and so turning the screw G in F. Fixed on F is a pointer I, by means of which and divisions on the band H^1, the distance of the point J from E can be regulated according to the temperature at which it is desired that the apparatus shall be operated. The screw C^1 is electrically connected with E and the bridge F. It will thus be seen that as the air in the box H expands by heat, the point J will force the diaphragm E into contact with D, so completing the circuit from C to C^1 and ringing the bell, or bells, in said circuit. Four claims are made.—No. 15741. October 4th, 1890. 8*d.*

AUTOMATIC ACCUMULATOR SWITCHES.—*W. S. Boult, Liverpool.*—This switch is designed for use especially in connection with electric accumulators or secondary batteries, its purpose being to maintain a nearly constant pressure in the mains in connection with the accumulator by varying the number of cells of the latter included in the electric circuit so as to compensate for variations of electromotive force in the battery. Fig. 1 is a plan not including either the "switch proper" or the pressure-meter, Fig. 2 a side elevation of the same, and Fig. 3 a front elevation showing also a "switch proper." B is a switch shaft held in bearings C and carrying loose sleeves shown by dotted lines (Figs. 1 and 2). Each sleeve carries rigidly attached to it a bevel wheel D, ratchet wheel E, and three-toothed ratchet wheel A. A chain wheel F runs freely between A and E, and carries a pawl G engaging with the latter. F is thus free to move in one direction for "winding up" without turning the sleeve, &c.,

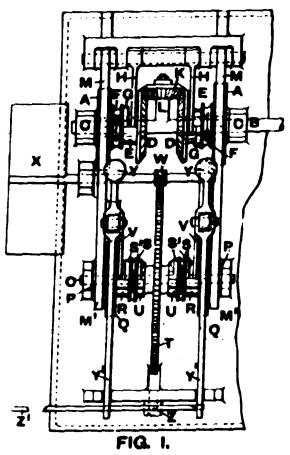

FIG. 1.

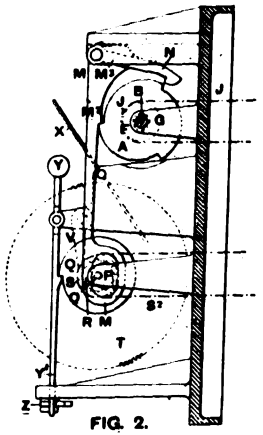

FIG. 2.

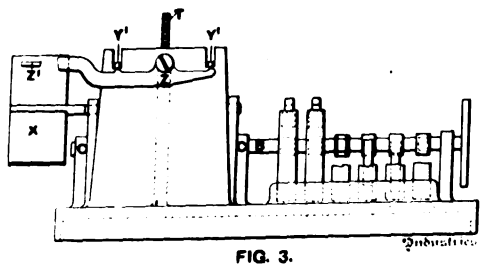

FIG. 3.

while, in the direction of the arrow, it carries these latter with it. A pawl H engaging with E permits motion only in the direction of the arrow. Chains J engage with the wheels F, which, by means of suspended weights, they tend to turn with the arrow. In gear with wheels D is a third one K carried on a stud L. M M^1 are levers pivoted at the end M, and having a slot or fork M^1 at the other end. A projecting tooth M^2 is formed to engage with ratchet wheel A, and a shoulder M^3 serves to lift off the pawl N. O is a fixed shaft on which, free to revolve, are the two eccentrics P, the two single-toothed ratchet wheels Q, the two ratchet wheels R (in each case, P, Q, and R being rigidly connected together), the two chain wheels S with pawls S^1, and the large toothed wheel T carrying the two ratchet wheels U. V V are pawls engaging with ratchet wheels R. This arrangement permits of the "winding up" of chain S^2. Wheel T is in gear with pinion W and rotates fly X. Y Y^1 are pawls for holding wheels Q carrying balance weights Y at one end and lengthened out as shown at Y^1. Z Z^1 is a lever for lifting the pawls Y^1, pivoted at Z and having its outer end Z^1 connected with the solenoid core above mentioned. The action of the apparatus is as follows:—Suppose the electric pressure in the mains gets too high. The end Z^1 of the lever Z^1 Z is lowered, the right hand pawl Y^1 is lifted, releasing wheel Q. Chain wheel S (driven by the chain S^2) now rotates, carrying with it T, U, R, and P. As P rotates, it lifts M^2 and allows N to be pressed by a spring against A. When Q has made nearly half a revolution, M^2 clears A, which, driven by F, at once flies round until the tooth just released by M^2 is arrested by N. Q, completing one revolution, again displaces N, at the same time pushing in M^2 immediately in front of the next tooth of A. Thus, as A is fixed to D, the latter is revolved one-third of a revolution, so rotating B through one-sixth of a revolution, and forces a contact arm on B out of contact with one of the terminal plates connected to one cell of the battery, the arms on B being spaced helically around same. When the pressure falls too low the other pawl Y^1 is lifted, and the other half of the apparatus generally is brought into play. Seven claims are made.—No. 1026. January 20th, 1890. 8*d.*

ALTERNATING CURRENT METERS.—*H. H. Lake, London.* (*E. Weston, Newark, New Jersey, U.S.A.*)—In the annexed illustrations Fig. 1 shows a plan, Fig. 2 a central section at right angles to Fig. 1, and Fig. 3 a detail section at right angles to Fig. 2, of a meter embodying the principle of this invention. A is the base of the instrument suitably recessed to receive the two bobbins B, placed end to end and surrounded by coils of fine insulated wire connected in series. The bodies of these are

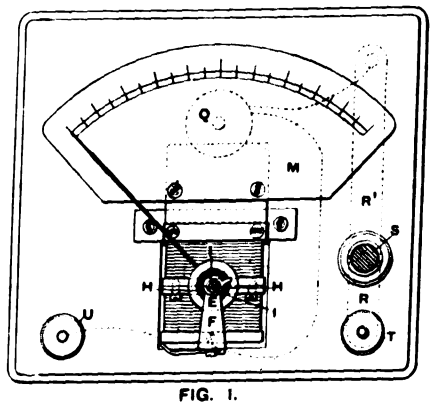

FIG. 1.

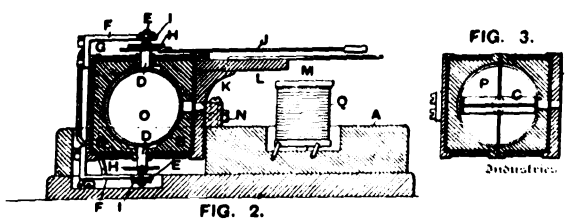

FIG. 2.

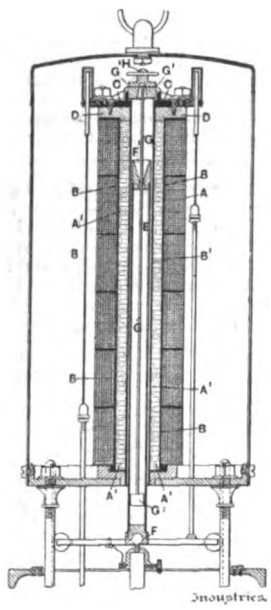
FIG. 3.

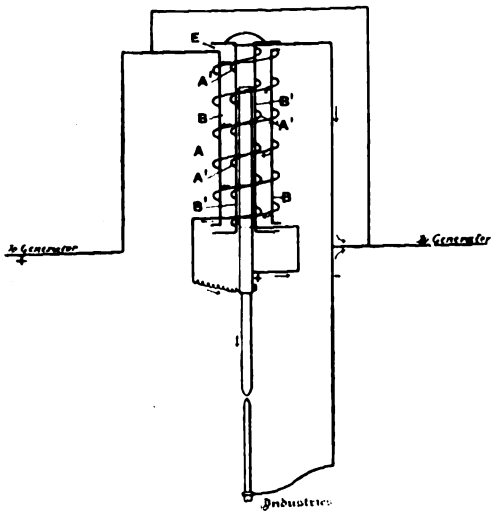
hollowed out to form a spherical cavity (Fig. 3). C is a circular frame of insulating material, on which is wound a coil of fine wire, the terminals of which are connected to the pivot pins D secured to said frame. These pins are journaled in the bodies of B, and have their bearings in adjustable steps E, supported upon the metal arms F. These arms are secured to an outer cover G. Surrounding the pivot pins D are spiral springs H, the inner ends of which are connected to said pivot pins, and the outer ends of which are connected to arms I, pivoted at the extremities of F. By turning these arms on their pivots the springs H H^1 may be contracted or expanded. Supported on the upper pivot pin is a light metallic disc, which carries an indicating needle J. The covering plate K carries a horizontal plate L, to which is secured a scale plate M, the whole being fixed to A by cross-piece N. Within the ring C is a sheet of mica O. This sheet passes through an opening in a diaphragm P of non-conducting material, held between the spools B, and extending diametrically across the spherical cavity in the latter. Q is an ordinary resistance coil, supported as shown. The two springs R R^1 of the contact push S are connected to binding post T and to Q as shown. The circuit of the instrument proceeds from binding screw U, through the coils of B, thence through movable coil on C, and from thence through Q to spring R^1. It will thus be seen that any reversal of the current will take place in all the coils, hence the needle will always be deflected in one direction. Claim: The meter substantially as described.—No. 12221. August 5th, 1890. 6*d.*



ELECTRICAL PRIMERS.—*A. Longsden, London.* (*F. Krupp, Essen, Germany.*)—The primer constructed according to this invention consists of a metal plug of cylindrical form, and having formed on its outer periphery, about equal distances from each end, a screw thread of a length equal to about one-third of the entire length of the plug. One end of this plug is enlarged, and is milled, and answers the purpose of a handle, the other or inner end being reduced in size to allow it to pass through the screwed hole in the breech block or other part of the gun. The plug has formed through its centre a hole, which is enlarged at its inner end. Passing through the smaller hole is an insulated wire connected at its inner end to an enlarged end of a cylindrical metal rod, which passes first through a suitable primer, pressed into paper and fitting the enlarged hole in the plug, and then nearly through a charge of powder. Around

Digitized by Google

the inner end of the smaller hole is a suitable ring of pasteboard, which forms a perfect tightening against the powder gases. A platinum wire is connected to the inner end of the plug, and projects upwards through the powder charge, and is connected to the end of the metal rod. To fire the gun, therefore, after the plug has been fixed, it is only necessary to connect one wire from the battery to the insulated wire passing into the plug and the other wire to another part of the gun. The electricity will be thus compelled to pass through the platinum wire, so heating it and exploding the powder charge. The inventor also describes a primer of a modified construction, in which the powder charge is fired by frictional electricity. Two claims are made.—No. 16534. October 17th, 1890. 6*d*.



ARC LAMPS.—*H. Harper, London.*—The invention relates principally to electromagnets or solenoids adapted for use with arc lamps. In the accompanying illustrations Fig. 1 is a vertical section of an arc lamp (one of a set connected in "series") embracing the principle of this invention, and Fig. 2 is a diagram

FIG. 1.

of the winding thereof. The solenoid proper consists of two bodies A A^1 of wire arranged concentrically but wound so as to conduct the current in opposite directions. The outer "series" coil A in the circuit of the lamp is wound upon a brass tube B. The inner "shunt" coil A^1 of fine wire is also mounted on a brass tube B^1; this coil, however, may be dispensed with when the lamp is connected in parallel. The upper part of B^1 is connected direct to a metal carrying plate C, and the tube B is also connected thereto by means of an insulating plate D. The core E consists of a soft iron tube of about the length of B. This tube is closed at the lower end by means of a plug F, and is provided at its upper end with a funnel-shaped and axially-perforated plug F^1 through which works a rod G. This rod is freely suspended at its upper extremity on a transverse pin G^1 mounted in a cap H above the carrying plate C, whilst attached to the lower extremity of the rod is a plunger G^2, preferably of barrel

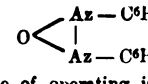


FIG. 2.

shape and fitting loosely within the tube E. Through the funnel-shaped plug the tube E is charged with glycerine or other suitable liquid, which acts as a dash-pot to prevent flickering in the lamp. The various connections are made substantially as shown in Fig. 2, and it will thus be understood that the attractive force of the solenoid upon the core varies inversely with the resistance of the arc. Five claims are made.—No. 13389. August 24th, 1889. 8*d*.

CHEMISTRY.

COLOURING MATTER.—*J. Imray, London.* (*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis & Dr. Chapuis, all of Paris, France.*)—The invention relates to the production of soluble blue colouring matter of the induline series derived from para-azoxyaniline—

The general mode of operating is as follows:—A mixture of azoxyaniline, hydrochlorate of aromatic amine and amine is heated to 160°-180° C. When cooled it is treated with water and hydrochloric acid, and the hydrochlorate of induline thus formed is precipitated by salt and zinc chloride. Example: 1 kilo. para-azoxyaniline, 0·7 kilo. dry hydrochlorate of aniline, and 0·4 kilo. free aniline are heated gradually to 160° C., and kept for one hour between 160° and 180° C. The mass is poured into water, then treated with boiling water and hydrochloric acid and filtered. The solution is precipitated by salt and zinc chloride. Claims: The production of soluble colouring matters of the induline series by fusion of para-azoxyaniline in admixture with hydrochlorates of amines and aromatic amines, substantially as described.—No. 1874. February 4th, 1890. 4*d*.

MISCELLANEOUS.

MEASURING TAPS.—*J. Baker, Oldham, Lancashire.*—In the accompanying illustrations Fig. 1 is sectional elevation, Fig. 2 a plan, and Fig. 3 a transverse section of a tap constructed according to this invention. The casing A is connected to the supply pipe through hole B, and has connected to it a delivery cock C opening into a recess A^1 in A. Working in A is a hollow plug D, large enough to contain the maximum quantity of liquid to be measured. Formed in D is a supply opening D^1 and escape slots D^2 formed substantially as shown in Figs. 1 and 3. Fixed in the top of D is a plug containing a valve E, through which the air is expelled as the liquid rises in D, until the ball float F, which normally rests upon wires G, is raised by the liquid and closes said valve. Also fixed to D is a handle H, by means of which the former may be revolved, so cutting off the supply from B, and bringing one of the slots D^2 opposite the recess A^1, so allowing a definite quantity of liquid to escape. The handle H also carries a segmental rack I, which gears with wheel J operating the registering apparatus K, and also a pin L, which is forced by means of a spring against the outer periphery of a ring M, fixed to A, and in which are formed notches, so situated that when the pin L becomes inserted in one of them the plug D will be so situated that one of the slots D^2 will be opposite A^1. Three claims are made.—No. 11215. July 18th, 1890. 8*d*.

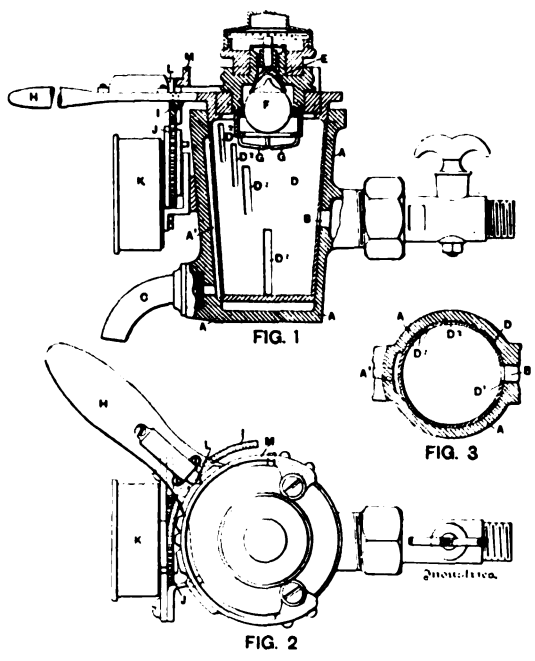

FIG. 1

FIG. 3

FIG. 2

PRESSURE GAUGES.—*W. M. Jackson, Manchester.*—It is well known that when testing the pressure in a closed vessel, containing compressed gas such as oxygen, hydrogen, &c., by means of a pressure gauge, the gas occupying the tube of the gauge is, when the cock which allows of communication between the vessel and gauge is opened, suddenly compressed and correspondingly heated, and so often causes an explosion. To prevent this the inventor introduces into the foot or other part of the shank of the gauge a suitable check or diffusing medium to prevent the sudden passage of the gas to the gauge, so that the pressure therein rises gradually. The checking plug for this purpose may be of any suitable form, one form being a metal plug screwed into the shank of the gauge. This plug has drilled centrally through it a fine hole, and has placed upon the top of it a number of alternate discs or layers of copper wire gauze or perforated metal and felt cloth or other pervious textile material. Claims: As an adjunct to pressure gauges interposing compressed layers of packing of suitable material in the conduit connecting the gauge to the compressed gas cylinder as described; (2) in pressure gauges an adjustable needle valve for the purpose as set forth.—No. 2314. February 10th, 1890. 8*d*.

COMPOUND ARMOUR PLATES.—*J. E. Bott, Eyam, Derbyshire.*—This invention relates to the manufacture of compound armour plates by casting steel or alloy of steel with other metals on to a base of wrought iron. The wrought-iron portion of the plate is first made in the usual manner, and after being cleaned or pickled, is coated with nickel, aluminium, or other slowly oxidisable metal or alloy by electrical deposition. The said plate is then placed in a suitable mould after being raised to a welding heat, and steel or alloy of steel and other metal is then cast on. If it is desired to give the plate a still harder coating, a hard steel face is cast on the top of the compound plate as follows:—The plate is heated to a welding heat and the required amount of steel poured on if the said plate has had a coating of steel or alloy having a percentage of nickel or other alloy which is sufficient to prevent oxidisation. If it has not had such a coating, the plate is pickled and then coated with nickel as before. Claims: (1) The process of manufacturing compound armour plates by preparing a wrought-iron plate, cleaning same, coating it with nickel or other slowly oxidisable metal, heating it to a welding heat, and casting thereon a coating of steel or alloy of steel and other metal; (2) the process, after the above operation, of again cleaning, coating with nickel and heating, and then casting a second and harder coating of steel thereon; (3) the employment in the above operation of the process of plating with nickel or other metal as described.—No. 20380. December 18th, 1889. 4*d*.

MANUFACTURE OF COPPER.—*T. Twynam, London.*—This invention relates to improvements in the production of blistered and refined copper from copper mattes, coarse metal, cupola metal, and other cupriferous material containing a large percentage of iron. For the above purpose the inventor uses a Siemens furnace or an ordinary reverberatory furnace, furnished with a lining of chrome iron ore made coherent, as described in patents Nos. 8358 and 8359 of 1886. Suitable silicious material is charged with the copper "mattes," or coarse metal, to form an easily fusible silicate of iron slag. For this purpose silicious copper ores or slags are suitable. When a reverberatory furnace is used, an air blast should be used to assist the oxidation of the iron. The silicious slag is skimmed off from time to time, more silica being added if required to carry off the oxidised iron as silicate. When the iron is removed the copper is in the state of white or pimple metal, the addition of silicious material is stopped, and the silicious slag removed, the air blast being continued, and a little lime or limestone added to form a basic slag. The charge may be tapped when so converted into blister, or it may be worked into refined copper in the same furnace. Claims: The treatment of coarse metal, cupola metal, and other copper mattes, in furnaces lined with chrome iron ore in presence of a silicious slag with subsequent treatment in presence of a basic slag, substantially as described.—No. 560. January 11th, 1890. 4*d*.

JOINING LEAD PIPES.—*C. H. Smith, Irk View, Rhodes, Middleton, & B. Cooper, Manchester.*—To effect the above the inventors form on the respective ends of the pipes to be joined a right or left hand thread respectively, or both, the two being then joined together by means of a white metal coupling, the interior of which is correspondingly screw threaded. When the ends of the pipes are formed with a thread of the same sense, they are brought to bear against each other by means of suitable lock-nuts. When forming the pipe ends respectively with a right and left hand thread the ends are bevelled off so as to fit against a corresponding surface formed in the interior of the coupling. Instead of bevelling the ends of the pipes a rubber or leather ring may be employed, against which the ends of the pipes are screwed, so effecting a perfect joint. To effect the screw threading of the ends of the pipe the inventors first reduce the ends of the pipes by means of a reducing die formed with a cylindrical hole, the mouth of which corresponds with the diameter of the pipe before compression, and the inner end with that after compression, there being a conical shoulder formed between the two diameters, which effects the gradual compression of the lead pipe on the die being forced thereon. After reducing the end of the pipe the reduced end is placed in a die screwed internally with a thread corresponding to the thread to be formed in the pipe. The end of the pipe is then expanded by driving a conical plug into same, so forming a thread on the outer surface thereof, as will be understood. Claims: (1) The method of forming a thread on the respective ends of lead pipes by compressing and afterwards expanding the same, or by expansion only; (2) the lead pipe compressing or reducing die formed with a cylindrical hole of two different diameters substantially as set forth; (3) the expansion die formed internally with a thread, against which the pipe ends are expanded by suitable means as set forth; (4) the expansion die in combination with a conical expansion plug substantially as described.—No. 8942. March 13th, 1890. 8*d*.

APPARATUS FOR TREATING ORES.—*T. Young, Glasgow.*—The apparatus constructed according to this invention is for the purpose of treating ores to obtain precious metals. The apparatus is combined with an ordinary filter tank, into which the ores, after treatment with chlorine and the solution formed thereby, are emptied from a chlorinating vessel. The solution passes through a filter bed into a space beneath a false bottom at the lower part of the tank, and this lower space is put, by means of a pipe, in communication with an air-tight vessel, made preferably of iron or steel, protected internally by rubber. The air-tight vessel is fitted with an inlet pipe and stop-cock for steam, an outlet valve for air, and a pipe dipping down to or communicating with the lower part of the vessel, and leading to a position where it can be connected to a filter press. When a charge of material is about to be dealt with a vacuum is formed in the air-tight vessel by blowing steam and allowing it to condense, protosulphate of iron having been first put into the vessel either in solution or in crystals to be dissolved by the steam blown in. A stop-cock on the pipe communicating with the filter tank is then opened, and the chlorinated solution is rapidly drawn through the filter bed and into the air-tight vessel, in which the precious metal is precipitated by the action of the protosulphate of iron. When the reaction is completed steam is again admitted to the upper part of the air-tight vessel, so forcing the liquid and its suspended precipitate through the communicating pipe to the filter press, where the precipitate is separated from the solution Claim: The process of treating ores to obtain precious metals substantially as described.—No. 20181. December 16th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

PORTABLE HAULING AND WINDING ENGINES.

CONSTRUCTED BY MESSRS. JOHN WILD & CO., LIMITED, FALCON IRON WORKS, OLDHAM.

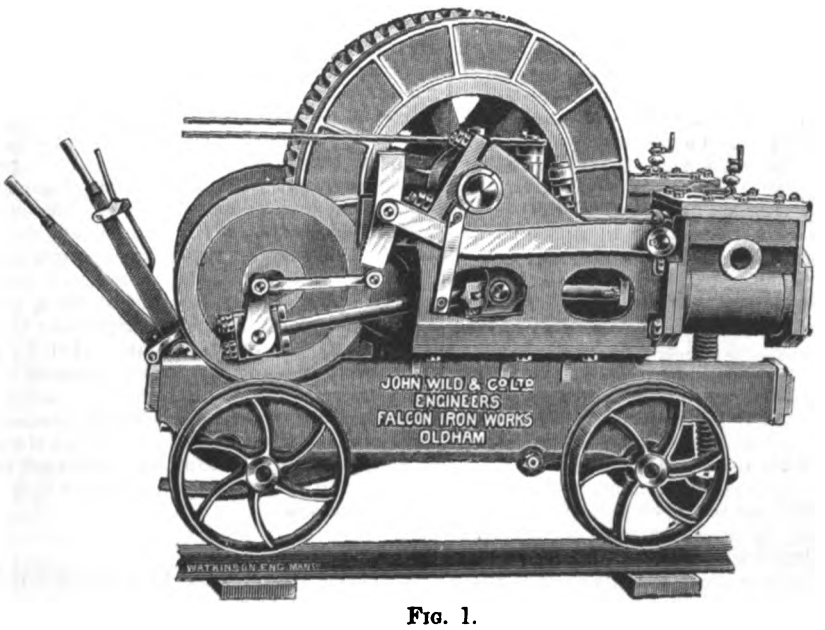

FIG. 1.

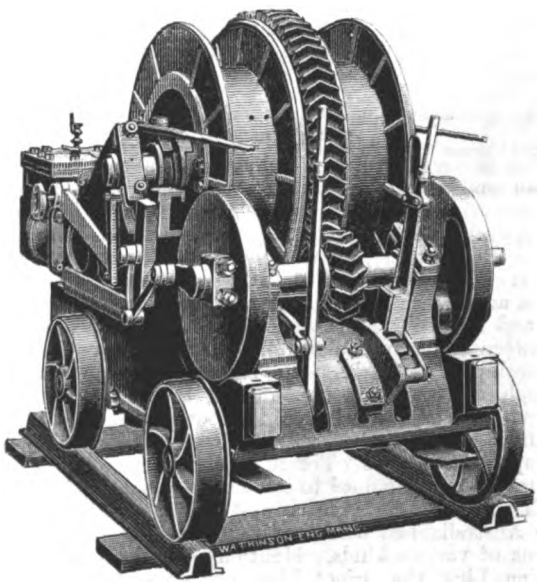

FIG. 2.

PORTABLE HAULING AND WINDING ENGINES.

THE accompanying illustrations, Figs. 1 and 2, represent front and end elevations respectively, and Fig. 3 a diagrammatic illustration of the valve motion of a compact pair of portable hauling and winding engines, as made for the Glamorgan Coal Company by Messrs. John Wild & Co., Falcon Iron Works, Oldham. They have been specially designed for underground work, and to stand rough usage by unskilled workmen. The leading dimensions of these engines are:—Height, 4ft. 6in.; length, 5ft. 4in.; and width, 3ft. 3in. The gauge of the road is 2ft. 9in., the diameter of the cylinders 7in., with a stroke of 10in., and the diameter of the winding drums is 2ft. It will be noticed, by referring to Figs. 1 and 2, that there is an absence of eccentrics, and that the slide valves receive motion by means of return cranks, actuating slotted links. This is a simple arrangement, and one which, we understand, gives very satisfactory results. Referring to Fig. 3, O represents the centre of the crank-shaft, C D the return crank, A the travel of the crank-pin, B the travel of return crank-pin, and the points F H E the travel of the pin in the link. As regards the brake, it consists of a cast-iron ring turned and fitted into a suitable recess in the drum, and arranged so that when pressure is applied to the lever the ring is expanded, so as to cause frictional contact with the drum. The slide valves are of an improved balanced type. These engines, we are informed, are made in various sizes.

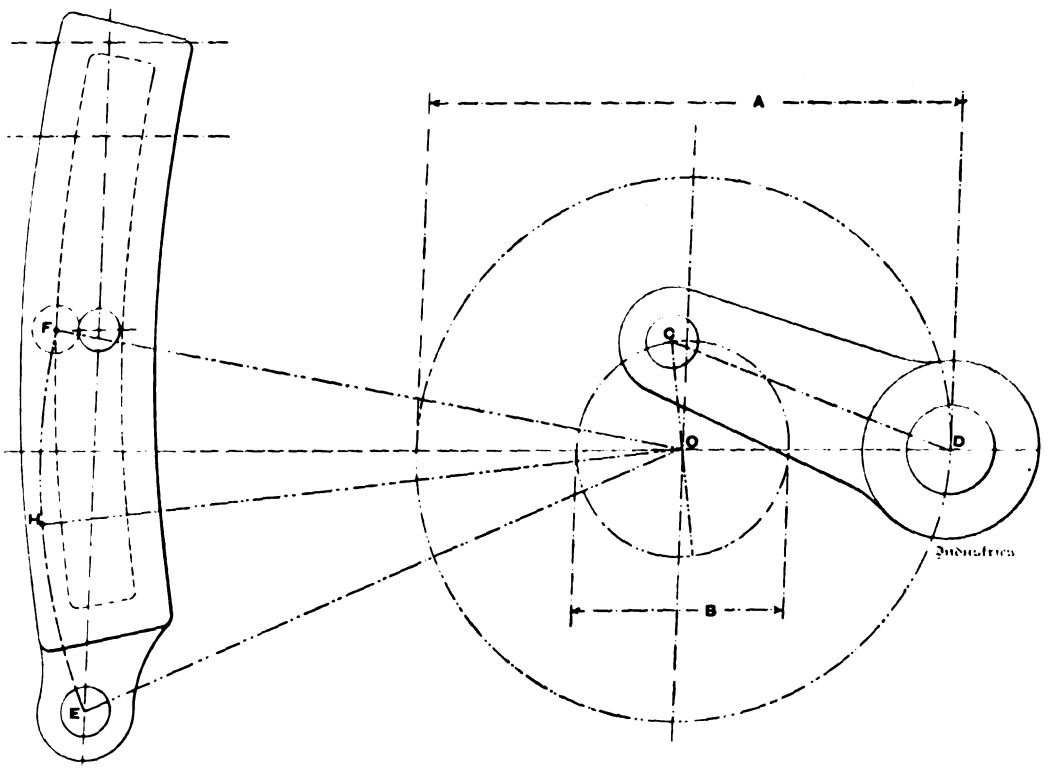

FIG. 3.

THE INSTITUTION OF CIVIL ENGINEERS.

AT a meeting on the 13th inst., Sir John Coode, President, being in the chair, a paper was read on "Auxiliary Engines in Connection with the Modern Marine Engine," by Mr. William Henry Allen, Assoc.M.Inst.C.E. The paper dealt with the early introduction of auxiliary engines for marine engines, beginning with the year 1870, when the surface condenser was fairly established and the marine engine had assumed the form of the twin compound engine.

Circulating Pumps.—Descriptions were given of the form of circulating pump used first in the "Arizona," which reached its maximum size in the engines on board the "Umbria," and also of the pumps which had been adopted for the large triple-expansion engines of the North German Lloyd fleet, and it was shown that the quantity of water required for condensing purposes had been reduced from 20lb. per i.h.p. per minute in the compound engine to 11lb. in the triple-expansion engine. The author recommended that the speeds for centrifugal pumps for large vessels should be 150 revolutions per minute, so that the machines should be fairly light, and yet possess full security from breakdown. The custom of duplicating had fallen into disuse, and most of the boats at the present time were fitted with single engines. Cast iron was to be preferred for centrifugal pumps in lieu of gun-metal, experience having shown that it was proof against the action of sea water. So far as the author knew, no experiments had been carried out on the condensing plant of marine engines, and consequently the data for regulating the size of the machines must be those obtained from practice. The author had found the friction of the condenser tubes, together with the velocity of entrance, as well as the friction of the circulating pipes themselves, to be equivalent to a head from 5ft. to 10ft.; that was to say, that in calculating from the speed of the centrifugal pump, as well as the quantity of water known to be delivered at this speed, from 5ft. to 10ft. of water was the pressure against which he had found it necessary to work. Comparing the quantity discharged with the indicated horse-power, the efficiency, with this head and with the moderate number of revolutions at which these pumps were operated, was found to be 50 per cent. This result was with a velocity of water of from 9ft. to 10ft. per second through the circulating pipes, which was usual in ordinary merchant steamers. In the Navy much higher velocities had been used—in some instances 15ft. per second, at which speed the duty of the centrifugal pump would be considerably diminished. The above efficiency must be considered fairly good when the large range of power for which the engines were constructed was taken into consideration. In twin-screw steamers safety of working was in a large measure assured by cross-connecting the circulating pumps, so that in case of emergency either of them could be employed for condensing the steam from both engines. This method had been recently carried out in the new mail boats, "Empress of India" and two sister vessels, for the Canadian Pacific Railway Company. In this ship the circulating pumps were attached to both condensers by cross-connections, with a system of valves. Each pump was provided with two engines, either of them being powerful enough to provide water for its own condenser for circulating, and the two together capable of working the pump at a sufficiently accelerated speed to provide water for both condensers. This method had the advantage of keeping down the area of the cylinders for circulating, while still retaining full power for bilging also.

Separate Air Pumps.—The practice of entirely disconnecting the air and feed pumps from the main engines and working them by their own steam cylinders was one which had not been universally adopted, but there were several instances of such separate sets of engines at work, giving great satisfaction. They

Digitized by Google

consisted of inverted cylinders working the necessary air pumps direct, and having connections to feed, bilge, and sanitary pumps on the cross-head, the strain acting through the piston rod and cross-heads directly on the pumps, an intermediate three-throw crank of ordinary description and fly-wheel on either end making the complete machine. These had been found to work very satisfactorily in the "Normannia" and other steamers of this class where they had been employed.

Fans for Forced Draught.—Fans for forced draught had been introduced on a large scale, in the City of Dublin Mail Steam Packet Company's Line running between Holyhead and Dublin, in the year 1883, and had since then been fitted to the vessels of the following lines:—The boats running between Belfast and Glasgow, the Liverpool and Isle of Man boats (4), Liverpool and Llandudno (2), Holyhead and Dublin (4), City of Dublin Steam Packet Company's (5), London and North-Western new steamers (2), Great Western boats running between Weymouth and the Channel Islands (3), Brighton and South Coast boats running between Newhaven and Dieppe (2), Chatham and Dover boats running between Dover and Calais (3), and the Netherlands Steamship Company's boats running between Queenborough and Flushing (4). From this list it would be seen that all the principal lines of passenger steamers running from England to neighbouring shores had been supplied with fans. Forced draught, however, had by no means been confined to coasting steamers, as recently all the Atlantic liners, as well as some boats trading to Australia, had been equipped with assisted draught fans of various kinds. Mention was made of Holt's China Line, the Orient Line, and also of the "Majestic" and "Teutonic," in which fans for assisted draught were applied. At present the pressures for forced draught varied from ½in. of water upwards according to the system, but until further progress was carried out in high-pressure boilers the author was of opinion that a pressure exceeding ¾in. of water in the ashpit was not advisable, as it involved leakage in the tubes and other troubles. Experiments made both in England and abroad showed that the large variation in the quantity of air required in the different systems made it almost impossible to give any proper rule. An instance of this might be found in the introduction of forced draught. The fans supplied to the later Queenborough and Flushing boats were some 18in. less in diameter than those of the earlier ones, and gave equally good results. These fans were employed only for assisted draught, but considerable benefit had been obtained with them, particularly when the wind was abaft the funnel, as the stokers then found the greatest difficulty in maintaining the pressure. The same might be said of steamers which travelled in the trade winds. All these fans were driven direct from their own engines, as it was impossible to work a high-speed belt properly when it was placed longitudinally with the ship, which was generally the most convenient way of arranging the fans. This, together with the proximity of dust and grease, rendered the system an unsafe one. All fans for high-speed engines should be secured to a substantial foundation. To bolt a high-speed fan against a thin plate bulkhead, without supports, would largely increase vibration, and possibly fracture the base-plate. The speed proper for the fans depended upon their diameter and the amount and pressure of air required; but as these had to be accommodated to the maximum speed which could be obtained without excessive wear and tear, for quick-running engines a speed of from 250 to 350 revolutions per minute might be regarded as the most satisfactory for long voyages. The efficiency of the combined fan and engine was not high, the best results obtained by the author being only 42 per cent., with fans of from 4ft. 6in. to 6ft. in diameter, suitable for steamship purposes. It was highly desirable to keep up the areas of the cylinders, so that, in the event of the steam pressure dropping, the cylinders should be sufficiently large to maintain the full speed required by the fan, and thus recover the pressure. For calculating the areas of the cylinder, an efficiency of 35 per cent. would ensure the engines being of ample power.

Reversing Engines.—At about the time centrifugal pumps were introduced, the auxiliary engine employed for the purpose of operating the reversing links of the main engines came into use. The form of engine first employed, and which was now in common use on small steamers, was that known as the "round-about engine." It had a cylinder of from 5in. to 8in. diameter, working the ordinary wheel motion. The crank on the second shaft was connected either to the weigh shaft of the main engines or to the links themselves, and arranged so that the links might be reversed ahead and astern. The reversing action took place by turning the steam into the exhaust by the ordinary central valve. For engines up to 150 i.h.p., where there was plenty of room, this arrangement answered the purpose well. It was also useful for heating up the main cylinders before leaving port by starting at slow movement, when a small volume of steam would be admitted on both sides of the main piston by the fact of the reversing engine bringing the links backwards and forwards from ahead to astern. While this form had been generally adopted for small engines, it had been almost entirely superseded in large ones during the last ten years by the direct-acting reversing engine. This was known as the hydraulic reversing engine. It consisted of a steam cylinder, the movement of the piston of which was controlled by an oil cylinder. These reversing engines were always fitted with automatic cut-off gear, so that the movement of the small hand-lever which controlled the steam valve was followed by the motion of the reversing engine only so far as was necessary, the automatic gear cutting off the steam and oil at the position corresponding to that in which the engineer placed the handle. This automatic cut-off controlling gear consisted of a set of differential wheels and levers which were positive in action; they were either connected to the weigh shaft or to the cross-head of the reversing engine, and by links and levers to the valves on the reversing engine. The operation of altering or reversing the position of the links having been accomplished, the hydraulic cylinder took upon itself the function of a locking gear, a valve preventing the oil from passing from one side to the other, and so securing the piston in the required position. The liability to thrusting of the link blocks was greatly lessened by the employment of the oil cylinder.

Electric Lighting Engines and Dynamos.—These were among the latest additions to the engines placed under the care of the sea-going engineer, but they had come into use so rapidly that it was now the practice to fit up cargo steamers, as well as passenger steamers, with them. The difference in the comfort of a ship furnished with electric light, instead of oil lamps, could only be judged by those who had had experience of both. A paper on this subject was read before the Institution by Mr. Jamieson, in 1884, since which time considerable advances had been made in perfecting the engine and dynamo for ship work. In the interval, nearly every variety of engine had been tried—turbine, three-cylinder, rotary, single and double acting, open and closed, high and low speed; but the general opinion appeared to be that the double-acting engine, specially constructed for driving dynamos, was the form which would find the most favour for marine work. At the present time, electric light machinery might be classed under two heads—viz., that specially suitable to Admiralty purposes, where the highest economy and efficiency were the principal qualities required; and that appropriate for ordinary merchant steamers, where a good, practical engine and dynamo were looked for before economy, except in some of the best Atlantic liners, where combined engines of economical form might be found. The question of driving dynamos direct from engines or by rope gearing had, the author thought, been settled by the general adoption of the direct-working machine, the advantages of dispensing with belting and gearing where oil, grease, and water were sure to be present being very great.

The author was of opinion that progress had been largely accelerated by the close specifications issued by the Admiralty, without which latent ability would not have been developed and such great improvements effected in so short a time. The economy of engines and dynamos had been improved, both by increasing the efficiency of the dynamo and by reducing the quantity of water required by the engine itself. Naturally, with a higher pressure of steam, combined with the use of the condenser, considerable reduction could be made by way of economy. It would also be seen that open engines had in themselves several advantages over closed engines—namely, accessibility, simplicity, and fair economy, combined with the all-important point of durability. It must not be forgotten that the twin-engine with cranks at opposite angles, such as was exclusively used at the Admiralty, had the advantage of working with considerably less vibration than the single-cylinder engine. For the mercantile marine, however, an altogether different type seemed to be preferred. With the exception of some of the largest liners, nearly all vessels were at present being fitted with single-cylinder direct-acting engines and dynamos, the object of the owners being to secure a machine which should run constantly without repair or breakdown, and one which could be readily understood by ordinary marine engineers, and repaired by them when necessary. The ship-lighting dynamo had been greatly improved during the last year or so, and the drum-wound armature machine was one which had been found to work satisfactorily. The armature consisted of a cast-iron hub mounted on a steel spindle, having laminated plates for the core, the whole being drum-wound on the outside. Every part at all likely to get out of order was visible, and could be readily repaired by those in charge of the machine. The voltage at which the author had found it most convenient to work in merchant ships was 60 volts, which was suitable for glow lamps as well as for projectors. Bearing in mind that the electric light engine had generally to work harder and longer than any other in the ship, the light being required both when in port and at sea, the matter of economy was of some importance. The efficiency of ordinary ship-lighting dynamos, such as those which had been constructed by the author with double-acting engines, was in some cases as high as 83 per cent. It would be observed from the table given that the efficiency of dynamos of the ordinary mercantile form was over 81 per cent. This result had been obtained from a number of machines of similar size, the curve showing the efficiency of engine and dynamo combined, from no load to full load.

The above description of auxiliary engines did not by any means exhaust the list of those which were to be found in the marine engine-room of the present day, as mention might be made of the present form of feed pump, which was generally of the duplex pattern without fly-wheel; also the evaporator with Weir's hot-water feed pumps; refrigerating apparatus, which had generally the horizontal compound engine with air pumps opposite to same; the steering gear, which was sometimes placed in the engine-room; the small engine for turning the engines round when in port; the distilling machinery; the air compressors employed when the cabins were ventilated by nozzles; and the ash hoists. The paper had, however, extended so far that it would be impossible to embody all the details of these engines, and the author had preferred to confine himself to the four classes of engine which were within his own experience.

A NEW PROCESS FOR GENERATING AND CUTTING THE TEETH OF SPUR WHEELS.*

The theory of the interchange system of gearing according to the solution first given by Professor Willis, in his treatise on the "Principles of Mechanism," is, "that in a set of wheels of the same pitch, having a constant generating circle for the flanks and faces of the teeth, any two wheels of the set will work correctly together;" and as a rack is a gear so infinitely large that its periphery forms a straight line, it follows that, if the rack teeth are also described with the same circle as that used for the wheels, any one of the set will run correctly with the rack.

The diameter of the generating or describing circle which gives one of the best forms of teeth for a set of wheels is equal to the radius of the pitch diameter of a 15-tooth pinion, making a 7½in. generating circle for one diametral pitch. The flanks of a 15-tooth pinion being radial, a 12-tooth pinion, which is the smallest generally used in practice, will have the flank of one tooth nearly parallel to that of the tooth following, thus allowing the space between the teeth to be cut with the regular gear cutter.

It was thought at the time this system was first brought out that its use would be very limited, as in the case of change gears for lathes and where it was found necessary to construct a train of gear wheels, but time has shown that it has many advantages over other equally correct systems not on the interchangeable plan, and it has been constantly growing in favour, until it is now almost universally adopted, especially among those using cut gearing.

Professor Edward Sang has also solved the same problem in another way, by taking the rack for the foundation of all curves for a set of interchangeable gear wheels. In the Sang theory, instead of using a constant describing circle, the rack acts as a constant generator, and the faces and flanks of all teeth throughout the whole set of wheels are described by it; therefore it is evident that, if the constant generating circle which is used for a set of wheels according to the Willis theory is also used to form the teeth of a rack, this same rack can be used in accordance with the Sang theory to generate another set of wheels, and any gear of one set will work correctly with the other.

For many years, one of the foremost mechanical problems in gearing has been to reduce these well-known theories to practice, and produce gear teeth having contours that correspond as nearly as possible to the theoretical curves. At first the teeth were drawn on paper or sheet metal, using arcs of circles which approximated the true curves, and then templets were made to these drawings by which the cutters were shaped; but it was found that cutters made in this way would not give as good results as desired, and afterward curves which were very much nearer the theoretical lines than arcs of circles were laid out by means of Professor Robinson's "Templet Odontograph," and cutters made from them with much better results. Later, the curves of coarse pitch teeth were laid out, and sheet-steel formers shaped to the lines as nearly as possible. These formers were then placed in a pantagraph machine, and cutters of the different pitches made from them; but it was found impossible, even with the large drawings, to make the formers sufficiently accurate. The epicycloidal milling engine was then constructed for generating and milling the curves of one diametrical pitch upon a steel plate, and, with these formers as a basis, cutters of any pitch were made. Thus step by step the process of making gearing with special cutters for each wheel, according to the Willis theory of the interchange system, has been brought to great mechanical perfection.

In the new process, which is the subject of this paper, instead of making all gears so that they will run in a rack, the rack is transformed into a cutting tool, and by it the teeth of wheels of any diameter are generated and cut at the same time.

Fig. 1 illustrates a gear-generating and cutting engine, designed and constructed by the writer, for the purpose of reducing to practice the principles of this process. The cutters are shown in position as they appear in the machine when the teeth are cut

* Read by Mr. A. Swasey before the American Society of Mechanical Engineers. The illustrations are taken from our American contemporary the *Engineering and Mining Journal*.

Digitized by Google

partly across the face of the wheel. The cutting spindles and the main spindle which carries the wheel are connected by means of change gears, the number of teeth to be cut in the wheel determining the proportion between the two on the same principle as the change gears of an engine lathe, which gives the cutting spindle as many revolutions to one of the main spindles as there are teeth in the wheel.

The cutting tool is composed of a series of cutters rigidly connected, which revolve and at the same time move longitudinally or endwise at right angles to the axis of the wheel to be cut; and, at the same speed, it is continually revolving at the pitch line, the motions being the same as in the case of a rack engaging with a revolving gear.

As it would be impracticable to continue moving the whole series of cutters endwise, they are bisected, and these segments are connected in series forming two sections, which revolve upon a common axis, and each section is given an independent endwise motion by means of a cam. When one section is engaged in cutting, it is carried endwise in the same direction and at the same velocity that the pitch line of the wheel is revolving, until disengaged from it, when the cutters, while continuing to revolve, are carried back by the cam to their original position, ready for the next tooth. By means of both sections, as they continually revolve and alternately slide forward while cutting, and back when disengaged, there is a continuous cutting and generating process of the teeth in the revolving wheel. The head carrying the cutters is automatically fed across the face of the wheel, and when the cutters have proceeded once across the gear is completed.

Fig. 2 is a side elevation of a bisected cutter, and Fig. 3 shows a series of six cutters, the end one being in elevation and the others in cross-section—these having cutting portions, which in cross-section represent the teeth of a rack, with the addition to the diameter of a given proportion of a pitch by which the clearance and fillets at the bottom of the teeth are made. If their cutting portions are formed of cycloids, then the whole set of gear wheels cut with them will be of the epicycloidal or double-curve system. If they are formed simply of straight sides, then a set of involute or single-curve gears will be generated and cut, or their cutting portions may be composed of both straight lines and cycloids and produce Professor McCord's recent system of gearing, which has composite teeth with the contours partly involute and partly epicycloidal.

All the cutters in a series are made exactly alike and interchangeable, the thickness of each or the distance from the centre of one to the centre of that adjoining being equal to the pitch of the gear to be cut. As indicated in Fig. 2, the two segments of the cutter are first made whole, with four holes in equal distance from the centre through which the rods pass that fasten them together. After the cutters are nearly completed, they are bisected with a narrow tool, leaving two holes in each segment.

Fig. 5 is a cross-section of the head, showing the mechanism for revolving and reciprocating the cutters. The rods which extend through the cutters serve not only to hold them firmly together, but to revolve them, and at the same time act as slides for the reciprocating motion. The spindles on both sides of the cutters through which the rods extend, are revolved independently and at the same speed by means of a parallel shaft having a pinion at each end which engages with a large gear on each spindle. By this means the four rods carrying the two cutter sections are revolved from each end, thus avoiding the torsional strain which would result if driven from one end only. The pair of rods for each section, after passing through one of the spindles, terminate in semi-cylindrical blocks. From these blocks studs extend, on which are journaled rolls, which engage with a cam held rigidly on the head. This cam is shown in Fig. 4, the working portions being made in the form of a screw thread, which, if extended all the way round, would have a lead equal to the thickness or pitch of the cutter. As each section of the cutters engages with the wheel only three-fourths of a revolution, the thread portion of the cam which carries the cutters forward extends only three-fourths of its circumference, leaving the other one-fourth for the reverse curves of the cam to bring the cutters back to their starting point. Provision is made for adjusting one section of cutters so as exactly to coincide with the other, making the spaces and teeth of the wheel equal, or, as is often necessary, the space can be made wider than the teeth by setting one section past the other. The variation of the spacing from one tooth to another is reduced to a minimum as the series of cutters act upon both sides of a number of teeth at the same time, and serve to average and eliminate any local inaccuracies in the division of the index and driving gears; also to obviate any tendency to crowd the wheel from one side to the other. The forward motion of the cutters and the revolution of the wheel at the pitch line being constant, the process of generating and cutting the teeth goes on continuously and uniformly around its entire periphery, so that one part is not heated more than another, but all the teeth are cut under exactly similar conditions, and when the revolving cutters have once passed across the face all the teeth in the gear are completed and given the correct form for each diameter of wheel, and as by the Willis theory all gears are cut to run in a rack, so by this process the same theory is put into practice and a rack is made to cut correctly all gears.

MECHANICAL AND CHEMICAL EQUIVALENTS.*

Mechanical Equivalents.—The expression "mechanical equivalent" is very frequently used, but imperfectly understood. This may arise, in part, from the fact that the term is incapable of definition. The next best thing to a definition is a good example. But it is not even possible to give an instance of a mechanical equivalent, which would be of universal, or even of general application. A device which is a mechanical equivalent in one combination may not be so in another.

The subject of "mechanical equivalents" should be approached in two distinct ways. The doctrine is applicable for two purposes only:—(1) On questions of infringement; (2) on questions of subject matter—viz., to raise a presumption that there is no invention required sufficient to support valid Letters Patent.

* Abstract of a paper read by Mr. G. R. Ellis, Solicitor and Patent Agent, before the Institute of Patent Agents on the 17th ult.

Dealing for the moment with the first branch of the question (that of infringement), there can be no doubt that a man who makes an invention consisting of a combination is entitled to restrain not merely persons who take the whole combination, but also others who take certain parts, and for the omitted parts substitute mechanical equivalents. A patentee need not, in his specification, claim mechanical equivalents expressly. Accuracy in claims is greatly to be desired; in fact it is impossible to bestow too much care or attention on the draftsmanship of claims. At the same time no amount of accuracy will be able to cover the inventive genius of the infringer. The inventor states how to carry out his invention. The infringer usually has another mode of doing the same thing. Moreover, a claim for a combination cannot do much more than claim the combination. A claim can direct the attention of the public to the features of the invention; but it is no province of the claim to describe the parts or their mode of action. The description of the parts and their action belongs to the specification; hence it is a well recognised rule, when dealing with claims for combinations, to make reference to the specification itself to ascertain what the invention is.

One of the most difficult problems that come before our notice is the question whether one combination is an infringement of the combination described and claimed. One difficulty lies in the fact that a claim for a combination cannot satisfactorily express the invention described. Another difficulty in our way, when determining whether a combination is an infringement or not, is due to the state of public knowledge. It has been said that in the construction of specifications regard must be had to the state of manufacture. It follows from this, therefore, that equivalency depends upon the state of public knowledge. At one time, and with one state of public knowledge, a combination might be held to be an infringement, whereas at another time, and with a different state of public knowledge, it might be held to be no infringement. Where an invention consists in an entirely new manufacture, devices which effect substantially the same object would probably be held to be within the ambit of the claim and to be equivalents of the devices used. Where, however, an invention consists in improvements on an old machine, the claim is more strictly limited to the devices specified, and the doctrine of equivalents has little or no bearing. In a certain sense, the question whether one device is a mechanical equivalent of another, is a question of fact; but it will be seen that, in reality, it is a mixed question of fact and law. It becomes a matter for the Court, eventually, to decide whether or not the alleged infringement is substantially the invention described in the specification, and *claimed* in the *claim*.

It has been judicially remarked that few infringers take the exact combination. The aim of an intelligent infringer is to take the substance of the invention, but to vary it in *form* and *detail* as much as practicable. In a recent case an infringer stated in open Court in support of his case (and utterly regardless of the rules of evidence), "I told my man not to make it *like* the patented machine." This remark would not be worth recording except for the fact that it exemplifies one view of the subject, namely, that a patent (at the least) covers all those modifications which a mechanic could make, merely using his mechanical knowledge. A change in form often alters the appearance of a combination. When, in addition to an alteration in form, there is an entire omission of certain parts and a substitution of mechanical means for effecting the same object, difficulties arise in determining whether there is an infringement or not:—

The following suggestions will materially assist in determining whether the combination be an infringement or not.

(1) In the first place study the specification and ascertain exactly the invention *claimed*.

(2) Examine the infringement and compare it *part by part* with the invention claimed.

If there be identity in the several parts the question is solved. If not, a further investigation must take place, namely:—

(3) Are the omitted parts material?

(4) Are the substituted parts in the infringement material?

(5) Do the material substituted parts perform the same function as the omitted parts?

It may be that the substituted parts not only perform the functions of the omitted parts, but either perform them better or perform others in addition. This does not make it the less of an infringement, although it might form the proper subject matter for a subservient or dependent patent. It would be a false deduction to say that a device is necessarily the equivalent of another merely because it effects the same result. An illustration will, I think, demonstrate that this is the case. There have been in recent years many inventions relating to "feed heaters," yet, from the mere fact of their performing the same work, it would be hasty to conclude that one was the equivalent of the other. I am, of course, using the word "equivalent" in its strict legal sense from a patent lawyer's point of view. The question is not so much whether the whole combination effects the same result, as whether the substituted parts perform themselves the same function in the combination as the parts that are omitted. It will be seen from this that the question of mechanical equivalents has an intimate relation with the parts in which they are combined, and this is the reason why it is impossible to give an illustration of a mechanical equivalent which is capable of wide application. In some combinations a spring and weighted lever would be mechanical equivalents, and in other combinations they would not. Or, again, in some combinations, toothed gearing and pulleys and straps would be mechanical equivalents, whilst in others they would not be so. If a universal instance were possible, it would probably be found that the two devices would cease to be mechanical equivalents, but would be found to be identical.

Subject Matter.—A favourite mode of impugning the validity of a patent is to allege that the patented invention is the same as one previously described, or differs therefrom merely by the substitution of mechanical equivalents. It will readily be seen that there is a great distinction in the doctrine of mechanical equivalents when viewed from the standpoint of infringement and that of subject matter. In the former case the principal question is, Does the substituted part effect the same result? The question in the latter case is, Does the substituted part, although performing the same function, perform others in addition, or render a combination generally more useful or of wider application, and was there any invention in making the substitution? There are many inventions which, although infringements of existing patents, are themselves proper subject matter for Letters Patent. In fact, all inventions for improvements must be infringements of the patented machine of which they are improvements.

Chemical Equivalents.—As you are aware, the law relating to mechanical inventions differs in many important respects from that relating to chemical inventions. These differences occur

Digitized by Google

more with respect to the "subject matter" of Letters Patent than to infringement. What I have said with regard to mechanical equivalents and their application to infringements applies also, in some measure, to chemical equivalents. There can be no doubt that in patents for chemical processes the substitution of chemicals which are known to chemists to have the same result would constitute an infringement of the patented process. It is possible, however, to give an instance or two of chemical equivalents which may be said to have a universal application. For instance, if in the prescribed process the use of an alkali was prescribed, say potash, an infringer would not be able to use the process merely substituting soda. In nine cases out of ten the two substances can be substituted in a process. Again, in some processes where treatment of sulphuric acid, for example, is directed, you find express directions to heat or keep heated at, say, 100° for four hours, with acid of a specified strength. It is well known that by using a stronger acid the operation will be completed in less time; or by using a weaker acid, the same result can often be obtained by an increase in the time employed; or in the same time by an increase of heat. This really amounts to mere compensation; and an infringer cannot escape the charge of infringement by altering a process in this way, even although, by his so doing, the product may be a superior one. I am assuming in this instance that the product of the reaction is the same or substantially the same. It sometimes happens that a variation of temperature, proportion, or strength of acid produces a different result; for example, a disulpho acid in lieu of a monosulpho acid, or a disulpho acid isomeric with the one originally described.

Dealing now with chemical equivalents, I should like to mention for discussion the question of "isomeric" bodies, and how far a claim for one isomer will cover another. I will state two problems with a view to discussion. An inventor X brings into existence, after many experiments, a *new acid*, which we will term A; which acid is capable of acting on a whole series of organic bodies, which, for convenience, I will refer to as B^1 to B^{12}. The result of the reaction in each case being a colouring matter. We will assume that A is an entirely new chemical substance at the date of the specification. Other investigators in chemistry are attracted by this discovery. One of them, Y, ascertains first that A is not a single chemical body, but is composed of, in reality, two substances, which I will call A^1 and A^2; and he describes means for separating these two bodies, and states that A^2 is comparatively useless, and that A^1 when combined with B^1 to B^{12} gives very fine colouring matters. Another investigator (Z) ascertains that there are bodies isomeric with A^1 and A^2, and which also yield colouring matters when brought into chemical relation with B^1 to B^{12}. Two questions arise in each case. Are the inventions of Y and Z patentable, and, even if patentable, can the use of them be restrained by A? In one sense (but a limited one) isomers are chemical equivalents—equivalent in the sense that analysis cannot show them to be different. Morphine and piperine are both represented by the formula $C_{17}H_{19}N.O_3$. Their action on the human body is, of course, very distinct.

IRON AND STEEL CONSIDERED AS BUILDING MATERIALS.

A PAPER was read before the Society of Architects on the 13th inst., by Mr. T. Claxton Fidler, M.Inst.C.E., on the above subject. In introducing his subject the author said that, while in relation to house building iron and steel have only occupied a subordinate position, yet in greater structures they have often been selected as the only available materials for the work to be performed. These structures, though designed by the engineer, properly belong to the domain of architecture, and often, in overcoming the structural difficulties, and properly proportioning the members to resist the stresses brought upon them, the designer has sinned grievously against the rules of æsthetic propriety. The property of strength, which is that which renders iron and steel so valuable to the engineer, is a complex thing. In this respect the various descriptions of iron differ widely, and though this variety is formed by the presence or absence of certain chemical impurities, yet chemical analysis does not adequately explain the widely different mechanical properties. Indications upon this point are to be found in the appearance of a fractured specimen. In a great measure, the capacity for enduring stresses is imparted to the metal by the mechanical work which is done upon it. With regard to the resistance of bars to direct tension, it is found that it varies from about 7 tons per square inch in cast iron to ten times that amount in strong steel. This, however, does not take into account the capacity of the metal of yielding to the stress without breaking, and if the ultimate breaking weight be multiplied by the yield and expressed in inch-tons, a bar of very mild steel will come at the top of the new list of strengths. First-class Yorkshire iron will run this steel closely. In dealing with rectangular beams, another circumstance has to be taken into account—viz., the difference between the results of experiments, and the assumptions as to what these should be as deduced by the most careful calculations from the known elastic stretching produced by directly applied stress. Theory failed to solve this problem, but experiments undertaken have led to the adoption of flanged girders, the metal being thus employed in a more economical fashion than when in solid beams. A new series of conditions again obtain in columns or other members subject to direct compression, the strength of short cubes of any material giving little indication of the resisting power of long columns of the same, on account of the tendency of the latter to bend. Beginning with the cubes, those of the hardest steel are found to be the strongest, but these are unsuitable for ordinary constructional purposes, and, omitting them, good cast iron is found to take the highest place, with a resistance of 35 to 40 tons per square inch, and then the medium and milder forms of steel—the lowest place being taken by wrought iron, which will only withstand some 16 tons per square inch. But, in a long column, cast iron is found at the bottom instead of at the top of the list, and the reason for this is found in its low resilience. The power of resisting direct compression, however, is always important, except in the most slender columns, and these should be avoided. This can be most readily and economically done by removing the metal from the centre and spreading it out as far from the axis as possible, either in the form of a thin tube, or in four legs braced together, when its efficiency will be found to be increased from tenfold, to fiftyfold, or even more.

The author said that, in considering the application of these materials to the construction of buildings, it is not only the utilitarian point of view from which they have to be studied, but also the æsthetic; and a few commonsense rules may be laid down, the first and most prominent being that untruthfulness of construction should be avoided, such as the copying of forms applicable only to brick and stone in this widely different material. This fault, however, is an old one, as may be well seen in the Lycian tombs, where the forms of an earlier timber construction are found to be copied in the unyielding stone. Similar things were done with iron when it was first introduced, but this is already being changed, though the transformation has hitherto been dictated entirely by scientific, and not by æsthetic, considerations. The construction, though, which has been worked out by the engineer, is evidently that which is most fitted to the material, and the iron architecture of the future will not be an architecture of masses or of broad surfaces, but one of lines, marking and emphasising the principal lines of stress, as similar lines were similarly marked in the stone architecture of the mediævalists.

POWERFUL CORLISS MILL ENGINE.

OUR illustrations on page 77 represent a side elevation and plan of a horizontal single cylinder Corliss engine of very large dimensions, constructed by Messrs. Robert Wetherill & Co., Chester, U.S.A., for driving a new beam train at Messrs. Carnegie, Phipps, & Co.'s Homestead Steel Works, Pittsburgh, U.S.A., which works we recently illustrated in connection with our description of the visit of the Iron and Steel Institute to America. The cylinder is 54in. diameter, with a stroke of 72in., and the estimated power of the engine is 3,500 h.p. The bed-plate is of the Tangye type, having the plummer block cast in the bed. The crank shaft, which is an open-hearth steel casting, is 27in. diameter in the journals and 30in. diameter in the wheel seat. The journals are 48in. in length, and are provided on either side of the shaft with adjusting wedges and screws. Power is transmitted directly from the engine shaft to the rolls by clutch couplings, which are also open-hearth steel castings. The fly-wheel is 27ft. in diameter, weighs 80 tons, and is made in segments planed and fitted together. An idea of the proportions of the engine may be obtained from the dimensions of the crank disc, which is 9ft. 4in. diameter, with a crank-pin 16in. diameter. The guide surfaces are cast independently of the bed, and bolted on. The cross-head is an open-hearth steel casting with a pin of forged steel. The trip arrangement is of an improved type, reducing the effort on the part of the governor in releasing to a minimum. The valve gear is proportioned for the unusually heavy service for which the engine is used. A distinctive feature will be observed in the arrangement of the valve levers connecting to the steam and exhaust valves, all of which are of the double-arm type, thus avoiding overhanging pins. For closing the steam valves vacuum pots are used, mounted on brackets secured to the steam cylinder. For convenience in starting and stopping the engine a by-pass valve is attached to the side of the main stop-valve chamber. The main stop-valve is fitted to an 18in. steam pipe. The exhaust opening in cylinder is made for a 20in. pipe. The valve-gear and valves being too massive to be moved conveniently in starting and stopping by the usual method of a lever entering the wrist-plate, a hydraulic attachment is connected to the wrist-plate for moving the valve gear, and in the event of the material fouling in rolls the engine can be stopped and reversed by the same attachment. The open-hearth steel castings used in the construction of the engine were furnished by the Standard Steel Casting Company, of Thurlow, U.S.A. We are indebted to our American contemporary, *The Iron Age*, for our illustrations.

A NEW LEAD PIPE JOINT.

WE illustrate herewith a new and ingenious method of making lead pipe joints, which has been patented by Messrs. Smith & Cooper, and which is likely to be extensively used. It is being introduced by Mr. B. Cooper, of Rhodes Mill, Middleton, Lancashire. The joint is made by forming on the two ends of the piping to be joined right and left handed threads, and then joining them by means of a coupling nut. To accomplish this a small case of tools, which can easily be carried in a workman's pocket, are provided. These consist of a diminishing tool, having an internal conical recess, which is driven

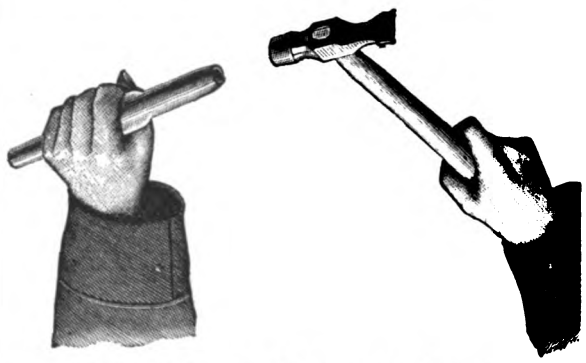

FIG. 1.—PROCESS OF DIMINISHING LEAD PIPE.

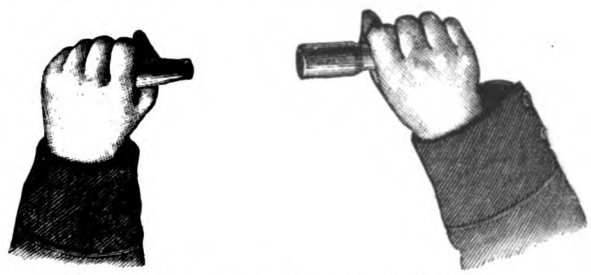

FIG. 2.—SKETCH OF LEAD PIPE DIMINISHED.

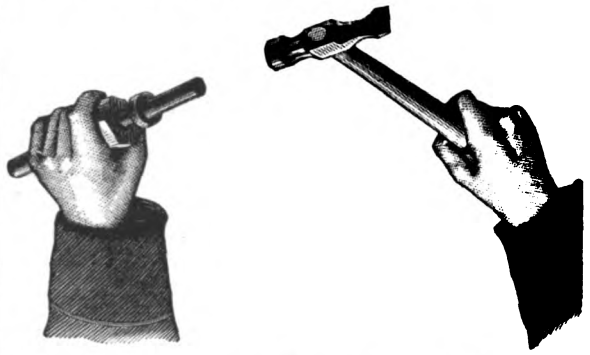

FIG. 3.—PUTTING THREAD ON LEAD PIPE.

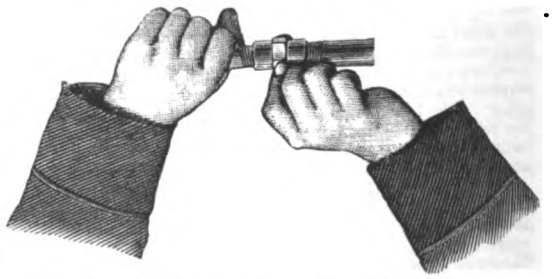

FIG. 4.—SHOWING JOINT WHEN COMPLETED.

upon the end of one of the pipes as shown in Fig. 1, thereby compressing it into a diminished conical shape, shown in Fig. 2. An internally screwed nut of the required size, and open at both ends, is placed on the taper end of the pipe, and into the latter a plug is driven (Fig. 3), which forces out the sides into the thread of the nut, thereby moulding a similar thread on the pipe. This process is repeated with a left hand threaded nut on the end of the other pipe, and afterwards the coupling is applied, as shown in Fig. 4. The maker claims that by this means a joint may be made in about one-fourth of the time required by the soldering process, that it does not require a skilled workman, and that the total cost of the new joint is considerably less than joints made by any other process. For removal purposes the joint may be uncoupled and remade by simply unscrewing or screwing up the nut. We are informed that the Manchester, Salford, and Heywood Corporations have granted permission to use these joints, in connection with their water supply.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 20th January, 1891.

Iron.—Little or nothing has been done in the iron trade here during the past week, and reports from the provinces testify to a general state of lethargy. The Paris Syndicate at their last meeting established the price for bars at 132s. 6d., and for joists at 140s. 6d., but business has been transacted as low as 128s. 6d. per ton for bars, and 136s. per ton for joists. Old iron rails are quoted at 72s. 4d. There is a fair prospect of business on the cessation of the severe weather. In a recent interview that Mr. Yves Guyot, the Minister of Public Works, had with the representatives of the suburban districts, he assured them that the lines of tramways which have for a long time been projected for the environs of Paris should be shortly put in hand. The supplying of iron work, to the amount of over 700,000fr., for a building in the Jardin d'Acclimatation here, has been entrusted to Messrs. Dubois & Nicolle, of Paris.

Coal.—It is expected that there will be large advances in the price of coal next week; retail dealers are commencing to ask as much as 50 per cent. increase on the current price for this article. Fuel is for the most part sent to Paris by water, the freight by rail being high, and an estimate can be formed of the situation here in looking at the empty canal boats which have now been lying ice-bound for the last month.

Copper, Tin, and Lead.—Prices have gone down 20s. per ton for all classes of copper without exception. First quality Chilian bars are officially quoted at £57, and ordinary Chilian bars at £55 the ton. There is also a general falling off in the prices for all kinds of tin, and the lead market is very weak.

Proposed New Customs Tariff.—The Customs Commission (*commission des douanes*) have finally adopted a list, from which the following duties on metals are an extract, and which now only awaits the decision of the Chambers. The discussion of this Bill will doubtless fill up a great part of next Session, and give rise to strenuous opposition on the part of the limited Free Trade party, as in most cases the duties are considerably higher than those existing under present treaties.

Proposed Entrance Duty per 100 *kil.* (220*lb.*).

French Submarine Cables.—The statistics of the Postes et Télégraphes, which have just appeared, give 1,000 as the number of submarine cables in use all over the world. The cost of these cables is about twenty million pounds. Of those which belong to Governments, Denmark owns 36, England 104, Germany 35, France 46, Greece 45, Italy 22, Spain 3, Brazil 19, India 72, and Norway no less than 236.

BERLIN, 19th January, 1891.

Iron.—The firmness of the iron markets continues, but the demand revives very slowly. The increase of business done is not sufficient to account for this firmness in prices, which has developed into a distinctly marked upward tendency for some classes of iron and steel. One of the causes which have operated to bring about a more stable state of things is the strong situation of the coal trade. With dear fuel and a prospect of still higher rates for coal, iron manufacturers were compelled to make a stand against the "bearing" influences of speculators. Another cause of no small importance is the prospect of large purchases of iron on the part of the Government. It is reported that the Landtag is to be asked to grant a credit of about 100,000,000 marks, 50,000,000 of which are to be spent in railway extension and in augmenting the rolling stock of the existing lines. Portions of the permanent way, too, are to be relaid with heavier rails. Though no great increase has taken place in the demand since the beginning of the year, inquiries are more numerous. There is manifestly a disposition on the part of consumers to buy more largely, which is held in check only by the exceptionally severe weather which has brought so many out-door works to a stand. The export trade remains in a languid state. The following statistics are instructive—the figures relate to the export trade of the years 1889, 1886, and 1883 respectively, in iron and steel:—To Russia, 67,190 (49,486, 66,890) tons; to Austria-Hungary, 24,363 (23,225, 60,537) tons; to Switzerland, 61,405 (50,477, 44,623) tons; to France, 13,844 (19,938, 48,483) tons; to Belgium, 40,268 (124,724, 53,111) tons; to Holland, 79,842 (108,569, 97,177) tons; to Great Britain, 72,020 (48,754, 66,816) tons; to Italy, 66,415 (73,786, 68,009) tons; and to North America, 53,024 (94,887, 71,887) tons. The figures for 1890 will show a serious shrinkage.

Soapmakers' Syndicate.—A meeting of the several associations of soap manufacturers was held the other day at Frankfort for the purpose of considering a scheme for uniting them into one "union." If this scheme be carried into effect, and, judging from the feeling of the meeting, it will be carried into effect, the soapmaking industry of Germany will be controlled by a "ring," whose first efforts will be directed to raising the selling prices, which are now very low relatively to the cost of production.

VIENNA, 19th January, 1891.

The Iron Market.—The enlargement of the boundaries of Vienna by the inclusion of its suburbs is likely to cause increased activity in the building trade, and hence also in the iron market, during next spring. Some important orders for rolling stock have lately been placed, the Southern Railway Company having ordered 10 locomotives, 80 goods waggons, and 50 passenger carriages, which are to be constructed by home manufactories. The Vienna Waggons Loan Company is about to increase its rolling stock by 500 waggons. As the result of long negotiations the Austro-Hungarian Iron Syndicate has been renewed for the next three years.

The Coal Market.—The coal market continues active. During the temporary stagnation of the traffic, owing to the snowstorms, the demand increased, and the traffic has resumed its former activity. The traffic returns of the various railways show the extraordinary amount of business done during the past year. The State Railways of Saxony forwarded 300,000 tons of Bohemian coals last year more than in the previous year. The Aussig-Teplitz line carried 1,660,000 tons to the Elbe last year, against 1,330,000 in the year 1889. The Dux-Bodenbach line shows an increase of 450,000 tons in the quantity of coal carried, and the Prague-Dux line an increase of 140,000 tons. These amounts show the increased production of Bohemian coals, and this increase may be expected to continue during the present year. The Northern Railway Company have not yet sold their coal mines, though the Credit Bank, Count Larisch, and Count Wolezek each offered ten million florins for them.

Electrical Engineering.—The Government has just granted to the Anglo-Austrian Bank a concession for the formation of the General Austrian Electricity Company.—Messrs. Ganz & Co., of Budapest, announce that the electrical central station constructed by them for the Roman Gas Company at Tivoli, near Rome, will be opened on the 1st May next.

The Customs Treaty with Germany and the Iron Industry.—Six years ago the Government, which has since that time been in power, saw the necessity of reducing the imports from Germany, in order that a chance might be given to native manufacturers of producing goods which up to that time had been imported. On this understanding capital was invested in new and already existing industries. Now that these industries are beginning to come into full operation, the treaty, which it is now proposed to conclude with Germany, will allow such goods as a short time were produced by our manufacturers under great disadvantages to be imported into Austria from Germany. It seems that we are thus departing from the principle that Austria should produce its own iron, and under such circumstances the apprehension which is felt by the iron industry concerning the new Customs Treaty is justifiable.

BRUSSELS, 20th January, 1891.

Iron.—There is but little that is encouraging in the near prospects of the iron trade. During the last week there has been a little buying on English account, and there are other orders of somewhat greater importance in sight in the same direction. Beyond this there is no improvement, and the depression is very great. Manufacturers are losing heart, and have begun to reduce the number of hands in their employ. Already a considerable number have been discharged, and much larger numbers are under notice to cease work at the end of the month. Production is now barely more than half what it was this time last year, but the requirements of consumers are insufficient to absorb even this restricted output. The amount of business done does not, however, represent the whole of the difficulties of the situation. Prices have dropped to an unremunerative level, so that on the few transactions which take place there is no profit; often a loss is incurred in executing an order. Every account received of the blast furnace industry speaks of fresh furnaces being blown out. No improvement is to be looked for till coal has become cheaper, and of that there is no immediate prospect. Several of the blast furnace owners have contracted for a six months' supply of coke from Germany. Shares in iron concerns are at a discount.

Coal.—The demand for house coal has increased so much of late in consequence of the exceptionally cold weather, which still prevails, that the falling off in other sorts, notably those suitable for metallurgical purposes, is not felt. Never were the coal markets, as a whole, more active than they are now. In the first week of the year the quantity despatched by railway from the pits amounted to 234,890 tons, against 190,110 tons in the corresponding week of 1890.

DÜSSELDORF, 20th January, 1891.

The Iron Market.—Trade looks more promising than a week ago. The pig iron stores at the Westphalian and Rhenish blast furnaces declined during the months of November and December, in spite of the many holidays in the latter month. The prices are generally the same, but best forge pig has risen to 54–56 marks. The finished iron trade is in a fairly good condition, but the makers of wire, and recently those of boiler plates, are suffering. The Saar and Lorraine district is very well off. The production of pig iron in 1890 was 1,012,030 tons, against 899,924 in 1889, the production of Thomas pig (all kinds of pig iron fitted for the basic process) having increased from 294,401 tons in 1889 to 331,003 tons in 1890. The Burbacher Works have lately blown down two of their blast furnaces, but they will be again blown in next spring when the new Bessemer steel works, which are now under construction, will be ready. These famous works have hitherto made only wrought-iron girders, and the new department will consist of two basic converters of 10 tons capacity each. The Völklinger Hütte, which is situated close to the Burbacher Hütte, is erecting a plant of the same capacity, and both will begin operations next spring. These works, in conjunction with those of Gebr. Stumm, make the Saar district a formidable competitor of the Westphalian district.

The Coal Market.—The market continues to be very firm. The Westphalian collieries are sold out for the first quarter of this year, and prices are rising. As the greater portion of the production passes through the hands of three syndicates at Dortmund, Bochum, and Essen, present prices seem likely to remain steady. The want of coal waggons on the railways continues, which is shown by the fact that the Erin pit, near Castrop, recently got only 15 waggons, while the administration had ordered 130, and the Hugo pit, near Carnap, only 35 out of an order for 110. The management of the railways is made more difficult by the disorder prevailing on all Dutch railways, which in the past weeks received 4,000 more waggons from Germany than they delivered. The coke market is in a very good condition. The current prices for smelting coke vary from 130 to 150 marks.

The Verein Deutscher Eisenhüttenleute.—At meetings held on the 21st ult. and the 11th inst., which were attended by some 500 members, papers were read on the American trip of last October. Mr. Thielen, Mr. Brauns, and Mr. Schrödter gave general *résumés* of the Southern, the Northern, and the Canadian trips, while Mr. Schlink and Mr. Schilling discussed the American blast furnace practice. Mr. Spannagel read a paper on "Rolling Mills," Mr. R. M. Daelen on "Steel Making," Mr. E. Klein on "Engineering Appliances," and Mr. Macco on "American Railway Practice." There was a very good discussion, in which Dr. Wedding took part.

Shipbuilding.—In German naval circles the most important event of the past year is, without doubt, the beginning of the four men-of-war of 10,000 tons each. Two of these big ships will be constructed at the Vulcan Works in Stettin, the third by the Germania at Kiel, and the fourth in the Imperial Wharf in Wilhelmshaven. The cost of each of them is estimated at 10,000,00 marks, excluding the cost of the armament, which amounts to 4,000,000 marks. Besides these ships, the building of a large yacht for the personal service of the Emperor is projected. In 1890 there were launched the "Aviso Meteor," in Kiel; the cruiser "Bussard," in Dantzig; the "Pelikan," in Wilhelmshaven; and the man-of-war "Beowulf." The latter represents a new type of this kind of ship, the first of which, the "Siegfried," was put in service in the spring. They have very powerful engines, the plates are 240 millimetres thick, and the guns are placed in two towers. They are primarily intended for coast defence, and it is intended to build eight more of this kind. By far the larger number of the German torpedo boats are constructed on the wharfs of Mr. Schichau, in Elbing, who is now proceeding to complete the number up to sixty vessels.

TRANSATLANTIC SERVICE.—The Norddeutsche Lloyd, whose fleet now consists of more than eighty steamers, has announced its intention to begin in March next to make three trips every week from Bremen to New York, and *vice versâ*, by fast-going vessels. The steamers will leave these harbours on every Tuesday, Wednesday, and Saturday. The latest steamer, the "Spree," of 9,500 tonnage, has made a very quick voyage. As these steamers call at Southampton, and also carry mails to England, all English firms having connections with the United States will be glad to hear of these new postal arrangements.

AMSTERDAM, 19TH JANUARY, 1891.

THE WEATHER AND NAVIGATION.—The difficulties of navigators in various parts of Holland, in consequence of the exceptionally severe weather, still continue. Amsterdam is not yet accessible, although a large staff is kept working night and day sawing through the ice in the North Sea Canal, assisted by the torpedo staff of the Royal Navy, which uses gun-cotton and dynamite to destroy the ice floes and ice blocks as soon as cut. The impression made is, however, not considerable. At Rotterdam an ice dyke is at last forming in the new waterway which seems likely to prove troublesome if the frost should continue. At Flushing the crowd of vessels—steam and sailing—unable to reach Antwerp still continues, and as many as 100 are now lying in the harbour or in the roads. Unfortunately the carrying power of the State Railways has nearly broken down under this sudden weight of cargoes, and the latest intelligence shows that only a proportion of the goods discharged by the incoming vessels can be moved to their destination. The other goods are either left in the ships or upon the quays waiting for despatch. Flushing has as yet no bonded warehouses, and this want is severely felt now, especially in the case of perishable merchandise, which is liable to damage by lying exposed upon the quays.

THE RAILWAYS.—The unprecedented block upon the main lines of the Dutch railways is still unabated, and if a general strike of workers were in full swing the state of things could not well be worse. It has been confirmed that goods from Germany are not at present accepted for transmission through Holland, and the goods traffic from Belgium has likewise been brought to a standstill. The annoyance and the losses falling upon traders and manufacturers, both home and foreign, are very considerable.

THE TRADE OF ROTTERDAM IN 1890.—From January 1st to December 27th, 1890, 4,437 vessels were cleared inward at Rotterdam, against 4,380 in 1888, and 4,432 in 1889. These totals do not include fishing craft. The tonnage entered was 3,784,500 in 1888, 3.973,200 in 1889, and 4,224,275 in 1890. This would tend to show that ships of a larger size are now availing themselves of the facilities that Rotterdam offers.

NEW COMPANY.—The articles of association have been approved in the case of the "Dutch and German Transport Company," with a capital of 250,000 guilders, formed for the purpose of organising transports between Holland and Germany, and trading upon the Rhine and other rivers and canals, either with owned or chartered steamers and sailing vessels.

STOCKHOLM, 17TH JANUARY, 1891.

PROJECTED IMPORTANT RAILWAYS.—As the natural resources of the country become more and more developed, the need of improved means of transport and communication naturally increases. The plan of connecting Ornsköldsvik with the North Tunnel Railway by means of a junction railway has long been under consideration, and is now likely to be realised, as it is hoped that the Government will introduce a Bill providing for its construction in this year's Parliament. Although the new railway, when completed, will no doubt prove an important one, it is neither a long nor an expensive line. The cost is calculated at 1,548,000kr., and the length is only 29 kilometres. Even if the cost should reach 1,800,000kr., as the officials of the State Railways have estimated, it is thought the contemplated line should be able to pay its own way. Of other new railways likely to be soon taken in hand are the lines between Trelleborg and Oxie, or some other point on the Malmö-Ystod line, and the Herniösand-Salleftea Railway.

SWEDISH WOODEN HOUSES.—This industry seems to be constantly increasing its market, the Swedish wooden houses being of a pretty construction, and also cheap. From Brazil an order has just been received for thirty of these houses.

REDUCTION IN THE OUTPUT OF TIMBER.—The efforts which have been made to lower the output of timber in Sweden have led to satisfactory results. The reduction agreed upon affects both Sweden and Finland, and amounts to about 30 per cent. of the production, which represents more than 11,000,000 pieces of timber, or, reduced into goods ready for export, some 350,000 "standards." It is stated, in a circular issued by the Export Society, that the proposal to reduce the present winter's output has been accepted by eighty-five of the timber exporters in the North, whose floatings last year amounted to 20,897,245 pieces of timber, and who have undertaken, subject to others following suit, to reduce their floatings during the present winter to an aggregate of 13,851,987 pieces of timber. There is to be a decrease in the output of timber from Norrland, for the present winter, of 7,045,258 pieces of timber, which is a reduction of about 34 per cent. as compared with last year's output. The society, in its circular, confirms the agreement entered upon. The reduction agreed upon in Finland reached about 4,000,000 timbers up to the end of 1890. Such agreements are sometimes regarded sceptically, but as the undertaking is given in the most binding manner, and as the society intends to control the output, there can be no reasonable doubt about its being faithfully carried out.

CHRISTIANIA, 17TH JANUARY, 1891.

THE PAPER INDUSTRY.—This industry is continuously increasing in Norway, which is a natural consequenee of the advanced wood pulp manufacture. The less favourable state of the wood pulp market has for the last few years caused manufacturers to search for some remedy, and the paper manufacture has thereby obtained a great impetus, which has brought about several important installations, with improved machinery. The Gjethus paper mills have been rebuilt, after the fire, in a very satisfactory style. The manufacture of paper will commence with two machines, to which two more will probably be added, and the manufacture of half-cellulose has also been decided upon. At the Bentse mills paper for newspaper is the main feature, and three of the machines are used for production, the raw material being wood pulp, both mechanical and chemical. At the Alvöen paper mills the make of packing paper has been at least partly abandoned for better kinds. The Bohnsdale, the Kleofos, the Strois, the Tinfos, the Graufos, and one or two other paper mills either have already started or are about to start new and extensive machinery. The Union Company paper mills, which are not yet completed, will probably be the largest establishment of this kind in Norway, and one or two other large works are projected. The number of paper machines has been nearly doubled during last year. With the great amount of available water power, and the production within the country of the most important raw material, Norway certainly possesses very fair chances of making the paper manufacture an important industry.

MADRID, 19TH JANUARY, 1891.

SHIPMENTS OF IRON ORE AT BILBAO.—The fall of snow has caused much inconvenience in the working of the mines, and many ships have been detained. Shipments of hematite pig iron have been chiefly for the Glasgow market. The market at present looks weak, and lower prices are expected, though the cost of production will probably remain the same. The expenditure on fuel will be lessened when Spanish coke is used in the Bilbao blast furnaces, but two years will probably elapse before coke is chiefly used in the furnaces.

THE COAL BASIN OF THE SOUTH.—The coal companies in the neighbourhood of Belmez, Espiel, and Peñarroya are now making large profits. The output for the year 1890 was 260,000 tons, whilst the amount sold was 330,000 tons, so that orders are in excess of the supply. Prices, therefore, continues to rise, large coal being sold at 24s., and small at 11s. The average cost of production is from 7s. to 8s., and mine owners are trying to increase the output in consequence of the large profit. An English company is supposed to be about to work some new mines, and if the prices are maintained in England, and the working expenses are kept low, the business is likely to be very profitable. The Gibraltar market may possibly receive its supply from this coal region if a line of railway should be made to a shipping port on the Guadalquiver.

COMMERCIAL RELATIONS BETWEEN CUBA AND SPAIN.—Since the revolution of 1869 there has been a tendency to use the term "ultramarine provinces" in place of "colonies," and progress has been made towards a total assimilation of Spain with her colonies. An important step in this direction was made when goods produced in the colonies were regarded as national goods and admitted into Spain free of duty, and in the same way Spanish goods were to enter free into Cuba, Porto Rico, and the Phillipine Islands. This measure was favourable to Spanish industries generally, and to the cotton mills in particular. Matters were going on satisfactorily until the passing of the McKinley Act. It seems almost impossible to reconcile the conflicting interests which have arisen with regard to the mother country and the colonies through the passing of that Act.

NEW YORK, 10TH JANUARY, 1891.

PIG IRON.—The past year breaks all records of pig iron production in the United States. As estimated by the *American Manufacturer* the total production for the year amounts to 9,091,979 gross tons, or 10,183,016 net tons, which is 1,666,937 tons in excess of 1889. Low prices and stocks accumulated caused the production in the second half of the year to be considerably below that of the first. In the Pittsburgh district production is much in excess of the demand, buying still being poor on account of the stringency in the money market. Bessemer pig, which a year ago was selling at $24, and is now about $16 per ton, must have nearly reached its lowest limit, as coke is 35c. dearer and ore $1 dearer than a year ago. The decision of twenty-three firms in the Shenango and Mahoning Valleys to shut down their blast furnaces to-day because of high coke and freight rates will result in making prices firmer. As these furnaces have 80,000 to 90,000 tons in stock, they can better afford to shut down than to continue in operation.

GOVERNMENT CONTROL FOR RAILROADS.—The Attorney-General of Nebraska, in his report to the Governor, deals with the railroad question in severe terms, and advocates the Governmental control of railroads. In speaking of the Board of Transportation composed of five State officers, of which he is one, he says that the system is a complete failure, as the railroads, by their influence, prevent adequate relief for the people. The report refers to the recent consolidation of interests in Western railroads, and declares that it is a menace to public rights requiring immediate attention. Government control is urged as the only remedy, as such consolidation furnishes an effective army for political work, and it is said that the political influence of railroads is already too strong. The report urges the Governor to bring the matter before the Legislature, so that it may send a memorial to Congress, and bring the question to an issue by foreclosing the lien of the Government on the Union Pacific Railroad Company.

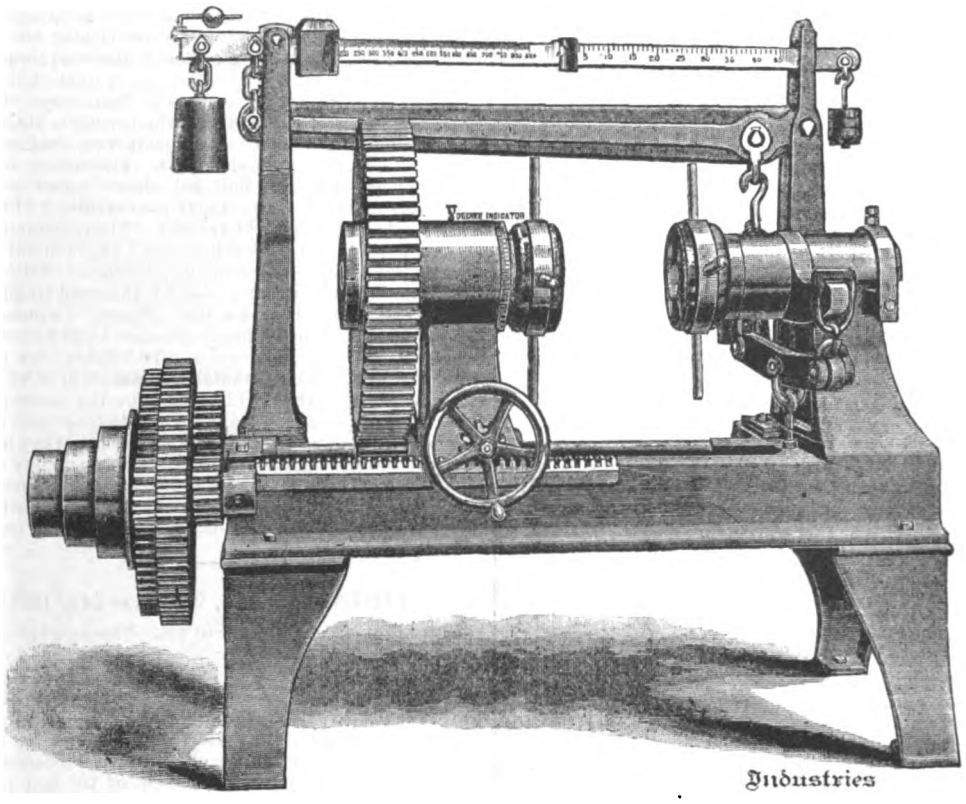
REPORTS OF RAILROADS.—The report of the Lake Shore and Michigan Southern road for the year shows that the gross earnings were $20,874,200; the expenses, $14,189,200; net earnings, $6,685,000. After deducting declared dividends, a balance of $342,010 is left. The annual report of the Michigan Central Railroad shows—gross earnings, $14,340,000; expenses, $10,514,000; net earnings, $3,826,000; and surplus earnings, $1,372,000. After deducting the share of the Canada Southern, and the amount of the declared dividend, there remains a balance of $102,091.

WOOL.—In its annual review of the wool trade of the United States the *American Wool Reporter* estimates that the total supply now on hand amounts to 92,820,000lb., as against 99,285,000lb. a year ago. The figures for the first ten months of 1890 show a total importation of 87,944,194lb., in comparison with 110,721,455lb. for the corresponding time last year, and in consequence of the lessened amount of foreign wool on the market there is a marked improvement in the wool goods business. The supplies of wool in the United States cannot be considered burdensome, the only weak spot in the outlook being the probability of increased importation of foreign wools after the beginning of the year.

PHILADELPHIA, 9TH JANUARY, 1891.

CHICAGO CANAL TO THE SOUTH.—The report of the chief engineer of the Chicago Drainage Commission favours a deep-water channel from Chicago to the Gulf of Mexico, as well as to the Atlantic Ocean. He estimates that a channel 20ft. in depth by 600ft. wide would actually cost less than the 8ft. depth and narrow width proposed by the Federal Government, because of the difference in location. The report recommends the abandonment of the lake front for other than refuge purposes, and in place of the lake front he puts the Chicago and Desplaines River and the proposed ship canal, with additional outlets through the heart of the city. The filling in of the lake front would give a large quantity of immensely valuable land, the income of which would in the end relieve Chicago of all taxation for the great waterway.

RAILWAY EXTENSION.—Details published in the *Engineering News*, show that the total addition to the railway mileage during the year 1890 was nearly 5,800 miles, or about 700 miles more than were laid in 1889. The total amount of railway completed on January 1, 1891, is 167,172 miles, and of this amount over 36,000 miles, or 22 per cent., have been constructed during the last five years. The greater part of the mileage for the year has been laid in the Southern States, where the rate has been increasing for a number of years, although it has been stationary or decreasing in nearly every other section.



MAKING A RIVER FREE OF TOLL.—The United States District Court has recently delivered an opinion fixing $209,000 as the sum to be paid by the United States to the Monongahela Navigation Company for lock and dam No. 7 in the Monongahela River. This is an important step in the contest being made by shippers, consumers, and owners of river craft for free navigation of the waters of the United States. Nearly fifty years ago the Navigation Company constructed a chain of seven slack water dams in the Monongahela River extending from Pittsburgh to a point near the West Virginia State line. This was done to enable navigation of the stream at all seasons, and has resulted in raising the river from one of comparatively no importance commercially to one of great use. At that time the general Government had little money to spare for such improvements. Toll is charged upon all shipments. There has long been a demand that the general Government should make the river free, and two years ago $162,000 was appropriated to buy one of the dams and make it free. The company refused to sell at that price, and valuers fixed the price at $209,390. The company appealed to the Courts, which have just decided that $209,000 is the amount to be paid. The company is likely to again appeal, as the Court held that the river belongs to the general Government, and nothing could be allowed for the company's franchise, the cost and earning capacity of the dam only being taken into account.

A LARGE IRRIGATION SCHEME.—The Bear Valley Irrigation Company has been incorporated in California, with a capital of $4,000,000, one-fourth preferred and the balance common stock. This company buys out the Bear Valley Reservoir property and the Alessandre tract of 216,000 acres of fruit lands, which is to be irrigated by the Bear Valley Reservoir water. Two million four hundred thousand dollars of the common stock is to be paid for these two properties, and the balance is to be sold to raise funds to build a new Bear Valley dam at a cost of $150,000 and also to convey the water to two irrigation districts comprising 510,000 acres of fruit lands.

AN IMPROVED TORSIONAL TESTING MACHINE.

CONSTRUCTED BY MESSRS. RIEHLE BROS., PHILADELPHIA, U.S.A.

AN IMPROVED TORSIONAL TESTING MACHINE.

THE above illustration represents a general view of an improved power torsional testing machine as built by Messrs. Riehle Brothers, of Philadelphia, U.S.A., for the Union Pacific Railroad, Omaha, Nebraska, the Russian Government, and the Thomson-Houston Electric Company. The machine was originally constructed for working by hand, but has since been altered for power working. The fixed head, shown on the right hand side of our illustration, carries self-centreing grips, and has arms projecting from either side of the grip head, the whole being supported on a knife edge. To prevent the grip head lifting from its normal position, the arms are attached to an equalising lever underneath; the latter is in turn connected to the weighing beams, on which the torsional stress on the body under test is recorded in foot-pounds, thus obviating calculation on the part of the operator. The cone pulley, shown on the left, has four diameters, and is driven from a counter-shaft. The levers and weighing beams are adjusted to the United States standard. The whole is made of the best material, and has been carefully designed. We are indebted to our American contemporary, *The Iron Age*, for our illustration.

FORMAL INQUIRY INTO THE BOILER EXPLOSION AT JARROW.

THE Board of Trade inquiry into the circumstances attending the explosion of a boiler at Messrs. Palmer & Co.'s works, Jarrow, on November 17th last, was opened on the 15th inst. The Commissioners were Mr. Howard Smith and Mr. Matthew McIntyre. Mr. K. E. K. Gough conducted the inquiry on behalf of the Board of Trade. The parties in the inquiry were Mr. John Price, as representing Messrs. Palmer's Shipbuilding Company; Mr. Joseph William Reed, manager of their engine works; Mr. J. F. L. Crosland, as representing the Boiler Insurance and Steam Power Company, with whom the boiler was formerly insured; and Mr. Neil McDougall, as representing the British Steam Users' Society, with whom the boiler was insured at the time it exploded. The explosion was caused by the collapse of the boiler flue. Robert Scanlon, forgeman, was struck by a piece of flying material and killed; two men named Porthouse and Johnson were severely scalded, and a man named Evans was slightly hurt.

Mr. Smith, in giving judgment, said the boilers in the forge were under the charge of Mr. Reed, with Mr. Alex. McDougall, foreman boilermaker, acting under his instructions. On the 25th of June, 1890, Robert Ritchie, on behalf of the British Steam Users' Society, examined the boiler in question, and he said he complained to the engineer in charge as to the defective condition of the boiler. The British Steam Users' Society, in their report to the Messrs. Palmer, said:—"The flue tube of this boiler is evidently in a somewhat serious condition, and should be replaced at an early opportunity." Mr. Price never saw the report of the British Steam Users' Society, having been obliged to leave on the morning when it came; but he had told them that if he had seen it he would still have continued to work the boiler. They desired to give Mr. Price every credit for the way in which he had given his evidence, but they could not help thinking that he had made that statement because of his desire to screen Mr. Reed, who had been in the employment of the firm for a very long time. Then there was a working examination made of the boiler on November 10th, 1890, and the British Steam Users' Society then, although they had previously said that the flue was in a somewhat serious condition, and they would like to see it replaced, made no allusion to it in their November report. The explosion was caused by overheating, acting on a plate which had become dangerously thin by corrosion. The thickness of the plate that exploded was from ⅛th to 5-32nds of an inch. They did not suggest that the attendant in charge of the boiler was negligent. They had been asked certain questions by the Solicitor to the Board of Trade with regard to the conduct of the different parties concerned. With regard to Mr. Crosland, they were of opinion that there was no need for his company to order a further hydraulic test after the test of 1885, or drilling of the plates. With regard to Mr. McDougall, of the British Steam Users' Society, they did not think that he, looking at the interests of human life and the dangerous properties of boilers, was justified in accepting the insurance of this boiler on January 31st, as he did, without making a proper inspection of the boiler, of which only a working examination was made. They believed that he was alarmed about the condition of the boiler after Ritchie's report, and that he believed it was not safe to work the boiler till Christmas. They did not think that Ritchie made a proper examination, and he ought to have drilled the plates. It must be remembered that Mr. McDougall's Society had insured a very large number of Messrs. Palmer's boilers, and he might not wish to find fault with a boiler unless it was really in a seriou condition. He sent a notice, and heard nothing; and, although he had another opportunity of communicating with them when the external examination was made, again he did not do so. He said now that it was safe to work the boiler till Christmas. The Commissioners' impression was that he might think so after the explosion, but that at the time he wrote the letter referred to he was of opinion that the boiler was unsafe, and they were of opinion that it was unsafe. They thought he was to blame for not putting his inspector's report into definite form, and also for not calling Palmer & Company's attention to it later. They came to the conclusion that no blame attached to Mr. John Price personally, but technically, as representing the company, he was to blame. They thought that Mr. Reed was to blame for allowing the boiler to be worked after receiving the report in July, but they thought he had rather drifted into error than gone into it wilfully. What he ought to have done on receiving that report was to have stopped the boiler at once. He should not have allowed his desire to work the boiler to have weighed against possible danger to human life.

Mr. Gough asked that an order for a portion of the costs of the inquiry should be made against Mr. Price and Mr. Neil McDougall. Mr. Smith did not make any order against Mr. N. McDougall, but against Mr. Price, not in his personal capacity, but as representing the Palmer's Company, he made an order for £40 costs.

THE CLEVELAND INSTITUTION OF ENGINEERS.

A MEETING of this Institution was held at Middlesbrough on the 19th inst., and proved one of the most important held for some years. The principal item was to discuss a paper by Mr. James Davis, of Park Gate Works, Rotherham, on "The Manufacture of Basic Open-Hearth Steel." The President, Mr. C. J. Bagley, in opening the discussion, said that, in his opinion, basic steel must come to the front for plates, as it had already done for rails. This was a matter which was of the greatest importance to Cleveland, with its phosphoric ores.

Mr. P. C. Gilchrist, of London, pointed out that if they made steel which would contain ·05 per cent. of phosphorus, and would contain carbon up to about ½ per cent., it was a matter of perfect indifference to a skilful steelmaker whether he started with a mixture in the bath containing 2 per cent. or $\frac{1}{10}$th per cent. of phosphorus. The official attitude regarding basic steel abroad was very satisfactory. The German, French, and Russian Admiralties all accepted basic steel for their boiler plates. In England the Admiralty were examining into the matter. The question was of immense importance to England, as last year we imported four million tons of hematite iron from foreign sources. He had no hesitation in saying that basic steel, made from any phosphoric ore, was fully equal to any made from English or foreign hematite, and would meet all the requirements of Lloyd's, the Board of Trade, and the Admiralty.

Mr. W. H. White, Chief Naval Constructor to the Admiralty, said that the position in which basic steel stood in regard to the Admiralty was that corresponding to that occupied by Bessemer acid steel, which was largely used, but which was not used for certain specific portions of ships. The Admiralty had been experimenting for the past three or four years to determine how basic steel behaved under the rough treatment of the shipyard. They had learned a great deal, and that these experiments were not finished was not their fault. Meantime they were using basic steel rivets with excellent results, and the engineering department of the Admiralty were using basic steel tubes of low tensile resistance as the material they preferred.

Mr. Milton, chief engineer and surveyor of Lloyd's, claimed that Lloyd's Committee had not "thrown cold water" on the process. All the trouble with basic steel for shipbuilding had been with basic steel of high tensile strength. Lloyd's had always taken the position of accepting steel by any process which fulfilled their tests, and at present works were manufacturing basic steel for shipbuilding purposes under Lloyd's tests, and had been doing so for three years.

"SERVE" RIBBED BOILER TUBES.

WE recently gave an account (see *Industries*, Vol. IX., page 435) of this latest departure in boilermaking, and we are pleased to learn that the satisfactory results therein recorded continue to be borne out by actual experience. The steamer "Phra Nang," in which the boilers were fitted with "Serve" ribbed tubes, has made a successful passage out to China, and the Fairfield Ship-

Digitized by Google

building Company has received a report from the chief engineer of the vessel, stating that the "Serve" tubes behaved quite satisfactorily throughout the voyage, and have caused an appreciable saving in the coal consumption. As there have been various circumstances which render it impossible to institute an exact comparison between the outward voyages of the "Phra Nang" to China and of the sister vessel in which the boilers are fitted with ordinary "plain" tubes, the steamship owners have expressed the desire that the two vessels shall complete three months' regular trading in the China Seas before a detailed report of the exact economy derived from the "Serve" tubes is made. Meanwhile the report just referred to must be satisfactory to the makers, Messrs. John Brown & Co., Limited.

Constant working of the boiler fitted with "Serve" tubes, with which the comparative trials were conducted at Sheffield, also confirms these experiences. At a recent comparative test of boilers Nos. 1 and 2, on the 15th inst., both under high "induced" draught, the former gave 15 per cent. greater evaporative efficiency and with slightly less fuel consumption. It is intended to continue the experiments with the view of demonstrating that with high accelerated draught, as commonly required in war vessels, the diameter of the boiler tubes can with advantage be largely increased, and thereby the choking of the tube ends—a common source of trouble when "plain" tubes of small diameter are adopted—can be obviated without any loss in evaporative efficiency.

THE INSTITUTE OF MARINE ENGINEERS.

A MEETING of this Institute was held on the 13th inst., when a paper was read by Mr. F. W. Shorey, on "Capital and Labour." The paper dwelt first with the origin of wealth, the source of the latter being set down as the material held by mother earth, until won from her hand by the skill and labour of man. Granting the materials to be at hand, labour is necessary for moulding them into shape for the purpose of commerce. The value of the products of work differs according to the facilities at command in the various countries for disposing of such products, while the climatic and national differences in respect to food, clothing, and other neccessaries of life tend to regulate the cost of production, and it may be added that the mental and physical culture of the working also affect the cost, and more especially the true value of the product. Reference was made to the recent strikes in London, and it was questioned whether any gain had accrued either to the country or to those particularly concerned in the strike except in a few isolated cases. The words of Sir H. Parkes were quoted, in which he said that the strike in Australia was almost as disastrous as a bombardment, and added that the country would suffer less at the hands of an enemy.

In the course of the discussion which followed the paper, it was urged that far too much had been made of the "labourer and his hire" in very many cases by agitators whose capital was the discontent they could ferment amongst classes of workers of all kinds. It was further urged that the wealth of a nation consists in the wisdom, skill, and brains of its rulers, that the brain of Nasmyth, which planned the steam hammer and gave it to the nation, had been more powerful for good than the brains of many scores of labourers, therefore it was meet that the brain, skill, and energy which direct capital and invest it in works which give employment to the labourer should be left as free and unfettered as possible. The proceedings were brought to a close by a vote of thanks to the author. The discussion will be continued on the 27th inst.

It has been proposed that premises should be purchased at Stratford for the better accommodation of the Institute, for the purchase of which £269 has been voluntarily subscribed. Further donations are promised.

SHIPBUILDING NOTES.

MESSRS. FLEMING & FERGUSON, shipbuilders and engineers, Paisley, have received notice of the arrival at her destination of the steam paddle tug "Mana," which they lately built and engined for the Timaru Harbour Board, New Zealand.

ON the 8th inst. there was launched from the yard of the Blyth Shipbuilding Company, Limited, Blyth, a screw-steamer, built to the order of Mr. W. Todd Moffatt, of Aberdeen. The steamer is to carry about 260 tons, and is intended for the coasting trade. She will be towed from Blyth to Aberdeen to receive her engines and boilers, which are being constructed by Messrs. Blaikie Brothers, of Aberdeen. The Blyth Shipbuilding Company have also several new vessels on the stocks in various stages of progress, and their graving dock is at present filled by a Hartlepool steamer. In addition to these the company are engaged with the extensive repairing of several steamers at their quay and in the river.

ON the 8th inst. there was launched, on the Tyne, from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington Quay, a steel screw steamer, the "Cragg," built to the order of Messrs. Fisher, Renwick, & Co., of Newcastle, and of the following dimensions, viz. :—Length, 180ft.; breadth, 28ft.; depth, 14½ft., and to class 100 A1 at Lloyd's. This vessel has water-ballast, and is also fitted with all modern improvements for the rapid loading and discharging of cargo, including three double-cylindered steam winches, windlass, large donkey boiler, steering gear amidships by Messrs. Davis & Co., Limited, and Hastie's screw gear aft. The engines, which are to be supplied by the North Eastern Marine Engineering Company, Limited, are of the triple-expansion type, having cylinders 13½in., 22½in., and 36in. in diameter, by 27in. stroke, and working at a pressure of 160lb.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, January 23rd, at 9 p.m. Lecture on "Some Applications of Photography," by the Right Hon. Lord Rayleigh, F.R.S.

MANCHESTER ASSOCIATION OF ENGINEERS.—Saturday, January 24th, at 7 p.m. Paper to be read: "Dynamos: the Consideration of the Chief Features which Regulate their Application," by Mr. A. B. Blackburne.

NEXT WEEK.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, January 27th, at 8 p.m. Ordinary meeting. Paper to be read: "Machine Stoking," by Mr. J. F. Spencer, M.Inst.C.E.

SOCIETY OF ARCHITECTS.—Tuesday, January 27th, at 7.30 p.m. Ordinary meeting.

SOCIETY OF ARTS.—Tuesday, January 27th, at 8 p.m. Paper to be read: "Lithography: a Finished Chapter of Illustrative Art," by Mr. William Simpson.

INSTITUTION OF MECHANICAL ENGINEERS.—Thursday, January 29th, at 7.30 p.m. Annual general meeting. Papers to be read: "On Some Different Forms of Gas Furnaces," by Mr. B. Dawson; "On the Mechanical Treatment of Moulding Sand," by Mr. W. Bagshaw; "Fourth Report of the Research Committee on Friction: Experiments on the Friction of a Pivot Bearing."

PRICES CURRENT, 21ST JANUARY, 1891.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: A better tone has been observable in copper during the past week. More business has taken place, with an improved demand generally. Stocks of copper decreased about 860 tons during the first fortnight of the present month, and Chili bars are 7s. 6d. to 10s. higher since our last report, being quoted to-day £53 2s. 6d. to £53 7s. 6d. cash, with moderate business. The revolution in Chili has tended to strengthen prices. Manufactured £65 to £66, "strong," with more inquiry.

TIN: Steady, at about last week's rates, the fluctuations during the week having been within narrow limits.

LEAD: Unchanged, with small demand.

SPELTER has advanced considerably, owing to short supplies, the Baltic ports having been closed by ice.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Rather more business is passing in chemicals. Sulphate of ammonia has a better inquiry, and prices are firmer. Benzoles are steady at late rates. Carbolic acids very slow of sale. The foreign demand for sulphate of iron continues very strong, and there is more inquiry for sulphate of copper for forward delivery. Muriate of ammonia and sal ammoniac are selling freely, but carbonate of ammonia moves off slowly. Chlorate of potash is firm, and chlorate of soda scarce; bichromates dull. Prussiate of potash has a fair trade, and higher prices are asked in some quarters.

HOME INDUSTRIES.

LONDON, 22nd January, 1891.

The Money Market.—The money market remains fairly easy, though there has been a slight hardening of rates from the lowest points touched. For some time there was no demand for loans for short periods, though no more than 1 per cent. was charged, and, in the absence of any supply of bills, discounts were done as low as 1⅛ per cent. The springing up of a fairly persistent demand for gold for the Continent stiffened rates a little from these points. The stock markets have been rather idle, and the movements have been variable and uncertain. Silver securities have not been very active, owing to anxiety as to the course of the new American legislation, and have simply followed the changes in the price of the metal from day to day. The cloud of labour troubles hangs over home railways, and, as the dividends so far declared have not been reassuring, this has been a drooping market. The frequent fluctuations in New York have prevented London from taking any hold of Americans, and prices in general are disposed to fall away. South American stocks, after being subjected to the influence of a fresh semi-panic, are inclined to recover. In mining shares there has been a fair degree of activity. In miscellaneous and industrial securities most attention has been given to American brewery shares, in which there has been quite a little boom.

Institution of Electrical Engineers.—On and after the 25th inst. the address of this Institution will be—Victoria Mansions, 28, Victoria Street, Westminster, S.W.

The Junior Engineering Society.—At a meeting of this Society, held on the 16th inst., a paper was read by Mr. P. J. Waldram on "Modern Hydraulic Lifts." The author first dealt with ordinary warehouse and passenger lifts. The difference between direct-acting and suspended lifts was explained, and the question of the balancing of direct-acting rams was entered into, Ellington's, Richmond's, and other balances being described. After briefly referring to telescopic and variable power lifts, and to the Eiffel Tower elevators, the author proceeded to the consideration of canal and ship lifts, illustrating the former class by the large canal lifts at Les Fontinnetes and La Louvière, designed by Messrs. Clark & Stanfield, and the latter by the lift at Bombay Harbour by the same engineers.

Detection of Flaws.—A trial of an instrument called the sciséophone, invented by Captain de Place, for detecting flaws in metal castings, was recently made in the presence of Sir Frederick Bramwell, Sir Benjamin Baker, and other eminent engineers and members of the Ordnance Committee. The pneumatic tapper is placed in connection with a telephone, a microphone being placed in the circuit. Many flaws were detected by the instrument, and the trial, though not entirely successful, showed that the apparatus is capable of being made thoroughly efficient for its purpose.

Association for the Improvement of Geometrical Teaching.—At a meeting of the Association, which was held at University College, Gower Street, on the 17th inst., Mr. R. B. Hayward, F.R.S., being in the chair, a paper on "The Use of the Term 'Abstract' in Arithmetic" was read by Miss Wood. A paper on "The Foundations of Geometry" was then read by Mr. E. T. Dixon. The author stated that he had worked out a subjective theory of geometry deduced from the two fundamental concepts, "position" and "direction." His paper consisted of a statement of his definitions, and showed how some of the propositions of elementary geometry were deducible from them. A paper on "Some Notes on 'Statics and Geometry'" was read by Mr. E. M. Langley, in which the author brought forward a new proof of Brianchon's theorem founded on statical considerations. A paper on "Another Voyage to Laputa," which was to have been read by Professor Minchin, the President of the Association, will be published in the annual report.

Business Announcements.—Messrs. Appleton, Burbey, & Williamson have just issued a full and well-illustrated catalogue of their electric light fittings, electric bells, and switches. Owing to an increase of business the firm has removed to more commodious premises, the Tower Bridge Electrical Works, Bermondsey, where they have erected new machinery for the manufacture of electric light fittings and patent switches and switch-boards.—Messrs. Thomas Barraclough & Co., Limited, who are engaged in the manufacture of wire rope machines, telegraph and electric cable making machinery and torpedo cable machinery, have taken offices at 20, Bucklersbury, London, E.C.

Report on Wool for the Past Year.—Messrs. Helmuth, Schwartze, & Co., in their annual report on wool state that, the state of trade during the past year has completely belied the favourable anticipations which were formed of it, and presents a striking contrast to the unbounded prosperity of the preceding twelve months. The downward course of prices may be attributable to a reaction from an undue expansion of trade in 1889. The activity of that year absorbed the largely increased supplies, and left the market absolutely bare of stocks of wool. The industrial activity of last year has been on a more restricted scale, partly in consequence of the 1889 legacy of stocks of goods, partly of the necessity imposed by the supply. Less goods to the extent of 100,000 bales River Plate wool have been manufactured, and there are short receipts from Russia and a heavy falling off in the imports of foreign and Mediterranean low wools. It is not too much to say that the decrease in the quantity worked up by the European industry is equivalent to 300,000 bales colonial wool; and not only has there been this enormous reduction in manufacturing, but the lessened quantity has passed into consumption at lower prices. Unquestionably a more normal state of things has thereby been brought about, and, though the situation looks nothing like so hopeful as a year ago, the probability is that it is in reality much sounder.

MANCHESTER, 22nd January, 1891.

The Linen and Jute Trades.—There has been a fair amount of business transacted during the week amongst houses catering chiefly for the home trade, and preparations are now in active progress for the holding of special sales. In the export business the market is slow, and the orders booked during the past few days have not been important. The Chilian troubles have a disturbing influence, especially upon firms interested in the "West Coast." Shipments are, of course, checked by these events. The Chilian market, though not amongst our largest, is one which merchants would be very sorry to lose. There is very little demand for United States' account, and Canada is not buying freely. The financial condition of many houses in the Dominion is unsatisfactory, and it will be some time before business recovers from the effects of recent shocks. The prices both of yarns and cloth continue firm, and there is continued strength in the low Irish end.

The Eight Hours Bill.—The Bury Trades Council, representing twenty-four trade societies, at a recent meeting unanimously passed a resolution to the effect that such a concession should be obtained rather by the organisations at present existing than by legislative action. This fairly represents the view of the general body of operatives in Lancashire.

An Improved Castor.—A neatly contrived castor for chairs, &c., has been devised by Mr. G. L. Scott, of Manchester. It is intended to obviate the difficulties arising from the ordinary construction of castor, where the roller is carried on a cranked swivel arm, which is easily broken off. The centre pin of the roller bearing is fixed in a small plate rotating freely round a centre pin secured in the body of the castor. The plate named, when pushed round into any position, rests on the base of the cup or disc of the castor, and is thus, while quite free to move in any direction, thoroughly supported in every position. It is, in fact, a well-supported universal joint. The castor is a great improvement on the older types.

An Improved Water Tap.—Messrs. John Horrocks & Sons are introducing an improvement in taps such as are used for water pipes in which a clack valve with leather washer below is forced on to a seat. When from wear the tap begins to leak, it is ordinarily difficult to renew the leather washer, but in the new tap a subsidiary clack is used by which the supply can be immediately closed to enable the renewal of the washer or repair of the disc valve.

A High-pressure Lancashire Boiler.—Messrs. Robert Taylor & Sons, of Marsden, have recently completed a Lancashire boiler for India, which is designed to work at the high pressure of 180lb. It is intended to supply steam for a triple-expansion engine driving a cotton mill in Bombay. The boiler is 20ft. long by 7ft. diameter, and is constructed entirely of steel plates ⅞in. thick in the shell. The end plates are ⅞in. thick, the front end being flanged and the back end attached by an angle ring 5in. by 5in. by ⅞in. The circular seams are double riveted with inch rivets and the longitudinal seams are treble riveted. The boiler has been hydrostatically tested to 325lb. in the presence of representatives of most of the boiler insurance companies in the district, with satisfactory results.

Proposed Quadruple Expansion Mill Engines.—It is stated that another attempt is to be made in the Oldham district to use quadruple-expansion engines. The late Mr. Daniel Adamson, about twenty years ago, fitted a set of engines on this principle in a mill near his works, but they did not work well and were finally abandoned. The pressures of those days were not sufficient, but as it has been shown that boilers can be easily constructed to bear 200lb. pressure, the problem is much simplified. The latter is the pressure to be adopted, and Messrs. Musgrave & Sons, Limited, are the engineers whose names are given in connection with the enterprise.

GLASGOW, 22nd January, 1891.

The Railway Strike.—The crisis on the Scottish railway system is as acute as ever. The struggle is now in its fifth week, having begun on the 21st ult. The mineral traffic is still extremely disorganised, and the large exporters are doing no business. The coal shipments from the two principal loading berths, the General Terminus and the Queen's Dock, show a decrease for the past four weeks, as compared with the corresponding four weeks last year, of 69,958 tons. The passenger service of the North British Underground Railway was suspended during Tuesday, the 20th inst., owing to there being no signalmen in the boxes in the tunnel. Passengers from the East had to alight at Bellgrove Station, about two miles from Queen Street terminus. The whole of the industries in the Glasgow district are suffering more or less acutely. The loss to the public is much greater than the loss either to the companies or to the men on strike, and unless a speedy end is put to the crisis the indignation of the long-suffering public will have become quite uncontrollable. The fact that there are faults on both sides does not tend to reconcile the public to suffer the loss consequent upon the dislocation of the railway service.

Pig Iron.—The annual statistical statement issued by Messrs. James Watson & Co. shows that the consumption of pig iron in Scotland during 1890 was greater than in any previous year, while the shipments were higher than in any year since 1884, and the stocks lower than in any year since 1878. The figures are—

	Tons.
Stocks, December, 1889	1,035,840
Production, 1890	798 333
Total	1,834,173
Shipments	442,377
Per rail to England	12,956
Consumed in Scotland—	
Foundries	346,782
Malleable iron works	419,613
Stock, December, 1890—	
Connal's stores	587,652
Makers' yards	25,793
Total	1,835,173

The furnaces in blast on 31st December numbered only 6, 134 being out of blast; but in the early part of the year 66 furnaces were in blast, 140 being in existence. Miners' wages are stated at 5s. 6d. per day, being 6d. in advance of wages in 1889. The average price for the year was 49s. 6d., against 47s. 9d. for 1889. The maximum monthly average price of the year was 61s. 1d., in January, and the minimum was 44s. 7d., in June, 1890.

Explosion of Two Gasometers. — An explosion, happily unattended by loss of life, but resulting in the destruction of two gasometers, took place on the 15th inst. at the gasworks of the Corporation of Glasgow, at Dawsholm, Maryhill. The occurrence will form the subject of an official inquiry, and in the meantime no authoritative explanation is possible. It is supposed, however, that some leakage had occurred, and that an amount of air was thus admitted into one or both of the holders sufficient to produce an explosive mixture. The gasometers had each a capacity of 1,600,000 cubic feet, and measured 90ft. by 160ft. Both the holders had been recently enlarged. One of them was made by a Scottish and the other by an English firm. The report of the explosion was heard at the West End of Glasgow, and a huge flame shot up from one of the gasometers. The roofs were blown off both, although fortunately the plates were not carried far. A third gasometer near the other two escaped injury. Indeed, it is remarkable that so little damage was done, the pits and the supporting columns being comparatively uninjured. If the third gasometer had shared the fate of the other two, a large part of Glasgow would have been left in darkness. The gasometers were about two-thirds filled with gas. The cost of the two together was about £22,000, but the wreck by no means represents a total loss.

The "James Watt" Dinner.—The annual dinner given alternately by the Philosophical Society and the Institution of Engineers and Shipbuilders was held this year under the auspices of the former. On the 19th inst., Professor MacKendrick, President of the Philosophical Society, occupied the chair, and among those who proposed or replied to the usual toasts were Sir William Thomson, President of the Royal Society, Professor Max Müller, Mr. George Herriott, of the Board of Trade, and others. The President, in pronouncing the usual eulogy upon Watt, made an interesting comparison between the human body considered as a machine for the transformation of energy and a steam engine.

(From our own Correspondents.)

LIVERPOOL, 21st January, 1891.

Visit of the Mechanical Engineers to Liverpool.—As the Council of the Institution of Mechanical Engineers proposed to hold their summer meeting this year in Liverpool, the Mayor called a meeting of the members of the Liverpool Engineering Society, local members of the Institution, and other representative men, to discuss the advisability of sending them a formal invitation. The meeting on Tuesday, the 20th inst., was largely attended, and it was unanimously resolved to send the invitation to the President. A strong executive committee was also formed to carry out the necessary arrangements.

Marine Engineers' Institute.—At a meeting of the Institute, on the 16th inst., a paper on "The Proposed Museum of Naval Architecture and Marine Engineering," was read by Mr. B. H. Thwaite. The author pointed out that most of the offices of the great shipping companies had a considerable number of models, which were, however, so placed as to be practically useless to the naval profession, and in many instances were neglected and dust-covered. Such a museum as that proposed would be of immense advantage to the owners of the models, as each owner could have his own model classified and kept distinct and apart from those of other firms. The proposed collection of models and naval engineering appliances would mark more conspicuously the stages of progress. The committee

Digitized by Google

of such a museum might institute rewards for seamanship, for inventions and systems designed for the amelioration and safety and conditions of the sailors, and for the progress of the science of maritime travelling and international commercial intercourse.

BUSINESS ANNOUNCEMENT.—The engineering business previously carried on under the style of Messrs. Simpson, Bruce, & Co., at 7, Rumford Street, Liverpool, will be transferred to the firm of Messrs. Simpson, Mackirdy, & Co., the services of Mr. Nesfield being retained under the new arrangement. The latter firm, which also had its offices at 7, Rumford Street, has now removed to new offices at 29, South Castle Street, Liverpool.

LEEDS, 21st January, 1891.

THE HULL AND DISTRICT INSTITUTION OF ENGINEERS AND NAVAL ARCHITECTS.—At a meeting of the Hull and District Institution of Engineers and Naval Architects on the 13th inst. a paper on "Art in Relation to Shipbuilding," was read by Mr. F. Somerscales (Earle's Shipbuilding and Engineering Company). The author said that the external form and structural details of ships, like all other constructive work, afforded ample opportunities for displaying an appreciation of art. Examples were given of different parts of a ship where the opportunity was afforded for manifesting an interest in art, amongst which the author mentioned the lower portion of the stern frame, the stem, the break of the poop, the "run" of the forward plating where it meets the stem, the position and relative proportions of the masts and rigging, and of the funnel.

PIG IRON STATISTICS.—The ninth issue is announced of Mr. E. W. Crawley's "Pig Iron Statistics," which gives the daily prices for 1889 and 1890 of Scotch, Cleveland, and hematite irons, together with 34 years' statistics of Scotch pig iron, showing the foreign shipment and consumption in Great Britain. The preface gives some useful information on the purchase and sale of warrants.

SHEFFIELD, 21st January, 1891

IRON AND STEEL.—The recent financial crisis at home, and the unsettled state of our best customers in South America, have stopped all new schemes and curtailed many of the old ones. There was a falling off in exports to the Argentine Republic of 17,000 tons during December, 1890, as compared with the last month of 1889. Pig iron of all grades is lower in price than has been the case for some time. Ordinary forge pig is from 42s. to 45s., and hematite, of which a large quantity is used here, may be bought for 62s. Merchant iron of all classes maintains a fairly steady value, and the best brands are firm at recent quotations. The Yorkshire makers of best brands are working to their full capacity on general orders for blooms, billets, and plates. The construction of ordnance and material for naval armament continues to steadily progress. Messrs. Thomas Firth & Sons have received another order for projectiles made on the "Firminy" plan, those previously made having given every satisfaction during the recent trials under severe tests.

COAL.—Fuel of all grades is in great demand. The railway companies appear to have been successful in obtaining their coal for 10s. per ton, instead of 10s. 6d. The increased consumption of gas is causing a large output of gas coal from the soft coal mines. London merchants are buying the best qualities of house coal heavily, so that, with the railway and gas contracts together, miners are fully employed. In the Barnsley district nuts are making from 8s. to 10s. per ton; slack, 4s. to 7s.; and common smudge, which a few years ago could not be disposed of at any price, is now selling at 3s. to 5s. per ton.

NORTH STAFFORDSHIRE, 21st January, 1891.

THE IRON TRADE.—There is a downward tendency in connection both with demand and prices, and the immediate outlook is distinctly unfavourable. Severe competition for orders for crude metal and finished material prevails, and buyers are able to get their own terms. Unless an improvement shortly occurs, there can be no no doubt that some general action will have to be taken with a view to reduce the cost of the raw material. A condition of things in which miners are receiving 50 per cent. advance in wages, and manufacturers are working without remuneration, cannot last.

SWANSEA, 21st January, 1891.

TYDEMAN'S DREDGING APPARATUS.—The executive committee of the Swansea Harbour Trust reported to the last monthly meeting, on the 12th inst., that after the extended trial given to Mr. B. Tydeman's patent apparatus for removing silt, &c., which is now fitted on the steamship "Princess," hired for the purpose, they are satisfied that it will be of advantage to the trustees to continue this system of maintaining the entrance channel. The trustees, therefore, adopted the recommendation of the committee to avail themselves of the option of purchasing the "Princess" at the agreed price of £2,950, less £1,040, being two-thirds of the amount paid for her six months' hire.

TINPLATES AND THE HARBOUR TRUST.—The consolidated rate on tinplates shipped from the port of Swansea has been increased from 1s. 3½d. to 1s. 4½d. per ton. Owing to the increasing trade, the Trust have found it absolutely necessary to provide additional warehouse room and lay down an extra line of railway. £2,500 are therefore to be expended on these improvements at the Prince of Wales Dock.

CARDIFF, 21st January, 1891.

IRON AND STEEL.—The steel rail trade is in an unsatisfactory condition, as the report of the Rhymney Iron Company's directors shows. Prices have fallen from £7 per ton at this time last year to £5 per ton, although the prices of raw material and labour are nearly as high. The principal ironmasters have large collieries, however, and the present high prices for coal enable them to reap an advantage in this direction. Still, the condition of the pig iron and steel trades is anything but healthy, and unless the demand expands additional furnaces will certainly have to be put out. Steel tinplate bars are quoted from £5 15s. to £6. Iron ore is steady. Rubio has realised 14s. 3d. per ton c.i.f. Cardiff for 50 per cent. iron. Freights from the Spanish ports are firmer, in consequence of a number of steamers being laid up.

COAL AND COKE.—The steam coal trade is active, and shipments have been maintained above the average. Business transactions have been limited on account of the inability of colliery proprietors to accept any new orders. Prices, naturally, are firm, with an upward tendency. No. 1 quality, 15s. 3d. to 16s.; No. 2 quality, 14s. 9d. to 15s.; No. 3 quality, 14s. to 14s. 6d.; No. 4 quality, 13s. to 13s. 9d. f.o.b. Cardiff. For house coal the demand is very brisk, and consumers experience considerable difficulty in procuring regular supplies Prices have advanced, No. 3 Rhondda being sold at 16s. to 16s. 6d. per ton, and No. 2, 15s. to 15s. 3d. Small steam coal is steady at 7s. to 7s. 6d. In the coke trade there is no change, the inquiry being limited. Foundry coke (best) realises 24s. to 25s.; ordinary, 23s.; furnace, 19s. 6d. to 21s.

BARROW-IN-FURNESS, 21st January, 1891.

HEMATITE.—A depression has set in in the hematite trade. Orders are not offering freely, and makers are not entering into many new contracts. The demand for Bessemer iron is restricted in consequence of the stoppage of the Moss Bay Steel Works in Cumberland, but confidence in the future is shown by the fact that steel makers are in some cases accumulating stocks for future use. Prices are easier at 53s. 2d. for warrants net cash, and 54s. for parcels of Bessemer iron net f.o.b. The output is shown to be greater than the consumption, and during the past week stocks have increased 1,562 tons, which represents the output of nearly three furnaces. Two furnaces have been blown out during the week, one at Moss Bay and one at the Solway Works, and now there are in blast 48 furnaces, and 28 out of blast.

STEEL.—The steel trade is fairly steady. Rails are in fair demand at £4 17s. for heavy sections, £6 for light rails, and £7 for colliery rails net f.o.b. The business doing in steel shipbuilding material is only small, and that is chiefly on local account, from which source prospects of new trade are most apparent. Prices are steady at £6 7s. 6d. for plates, £5 12s. 6d. for angles, and £7 2s. 6d. for boiler plates. Hoops are strong at £6 10s., and there is a good prospect in the casting and forge branches of the steel industry, but the other branches of the trade are indifferently supplied with orders.

SHIPPING.—The shipping returns are discouraging. The exports of pig iron and steel during the week were 11,337 tons, compared with 16,094 tons in the corresponding week of last year, a decrease of 4,667 tons. The shipments for the year, so far, amount to 39,905 tons, compared with 51,238 tons in the corresponding period of last year, a decrease of 11,333 tons.

MIDDLESBROUGH, 21st January, 1891.

PIG IRON.—The market is dull and there is scarcely any business doing. Buyers offer from 42s. 3d. to 42s. 6d. per ton for No. 3 G.M.B., but there are few or no sellers at these prices, as every day brings them nearer to the usual revival of trade with the opening season. The keeping back of iron for Scotland, through the railway strike, contributes to the dulness. Middlesbrough warrants are as low as 42s. cash buyers, 42s. 6d. sellers. Connal & Co.'s stock on the 19th inst. stood at 122,045 tons, being an increase since the beginning of the month of 6,159 tons. In hematite mixed numbers are 55s. 6d. per ton f.o.b. sellers.

MANUFACTURED IRON AND STEEL.—Finished iron is brisk enough on going orders, but new orders are not so plentiful as could be wished, so that some firms are open to easier terms than those quoted in the open market. Iron ship plates, £5 15s.; iron boiler plates, £6 15s.; common iron bars, £5 15s.; best bars, £6 5s.; best best bars, £7 5s.; iron ship angles, £5 10s. per ton, all less 2½ per cent. f.o.t. at manufacturers' works. Steel is duller, with a very quiet outlook. Some works are just resuming after the holidays. Prices remain much the same as they were. Rails (heavy), £4 17s. 6d. to £5 2s. 6d.; railway sleepers, £5 17s. 6d. to £6 10s.; ship plates, £6 5s. to £6 7s. 6d.; boiler plates, £7 5s. to £7 7s. 6d.; ship angles, £6 5s. to £6 7s. 6d. per ton f.o.t. at works.

SUNDERLAND, 21st January 1891.

THE SHIPPING AND COAL TRADE.—The freight market has shown some improvement, but this is far from being general, as is evident from the steady increase in the number of vessels laid up. One of the Sunderland shipowners has eleven vessels, of 24,000 tons deadweight carrying capability, idle on the River Tyne, but this is only a fractional part of the tonnage now withdrawn from working. The outputs of shipbuilders during the last two or three years have been so heavy that the laying up of less than one million tons of shipping cannot materially affect the general tone of the freight market, unless there is a continuation in the expansion of the world's transport requirements.

SHIPBUILDING.—The prospects for the present year are not so favourable as those of 1890. There are at present forty steamers, of 90,575 tons, and six sailing vessels, of 10,910 tons, in course of construction—*i.e.*, a total of forty-six vessels, of 101,485 tons, as against sixty-four vessels, of 142,789 tons, a year ago, only one of which was a sailing vessel. No new contracts are being entered into, and there is little reason to anticipate any improvement unless there is a substantial reduction in the cost of labour and material. Little progress is being made with work in hand, owing to the delayed delivery of steel angles and plates ordered from Scotland.

MARINE ENGINEERING.—There appears to be some uncertainty as to the refusal of the engineering employés to work overtime, but in the present state of trade an open rupture is scarcely to be feared. In addition to the construction of machinery and boilers for several new vessels, one of the local firms—Messrs. William Allan & Co., Scotia Engine Works—is fitting a complete set of new triple-expansion engines and boilers to the foreign steamer "Bergen."

THE PETROLEUM INDUSTRY.—Progress is being made by the Anglo-American Oil Company for the opening up of the oil-in-bulk trade at this port. Permission has been obtained for laying the necessary piping from the South Dock to the site of the proposed storage tanks. Two acres of land have been obtained, on which the works of the company, including three or four tanks, are to be erected.

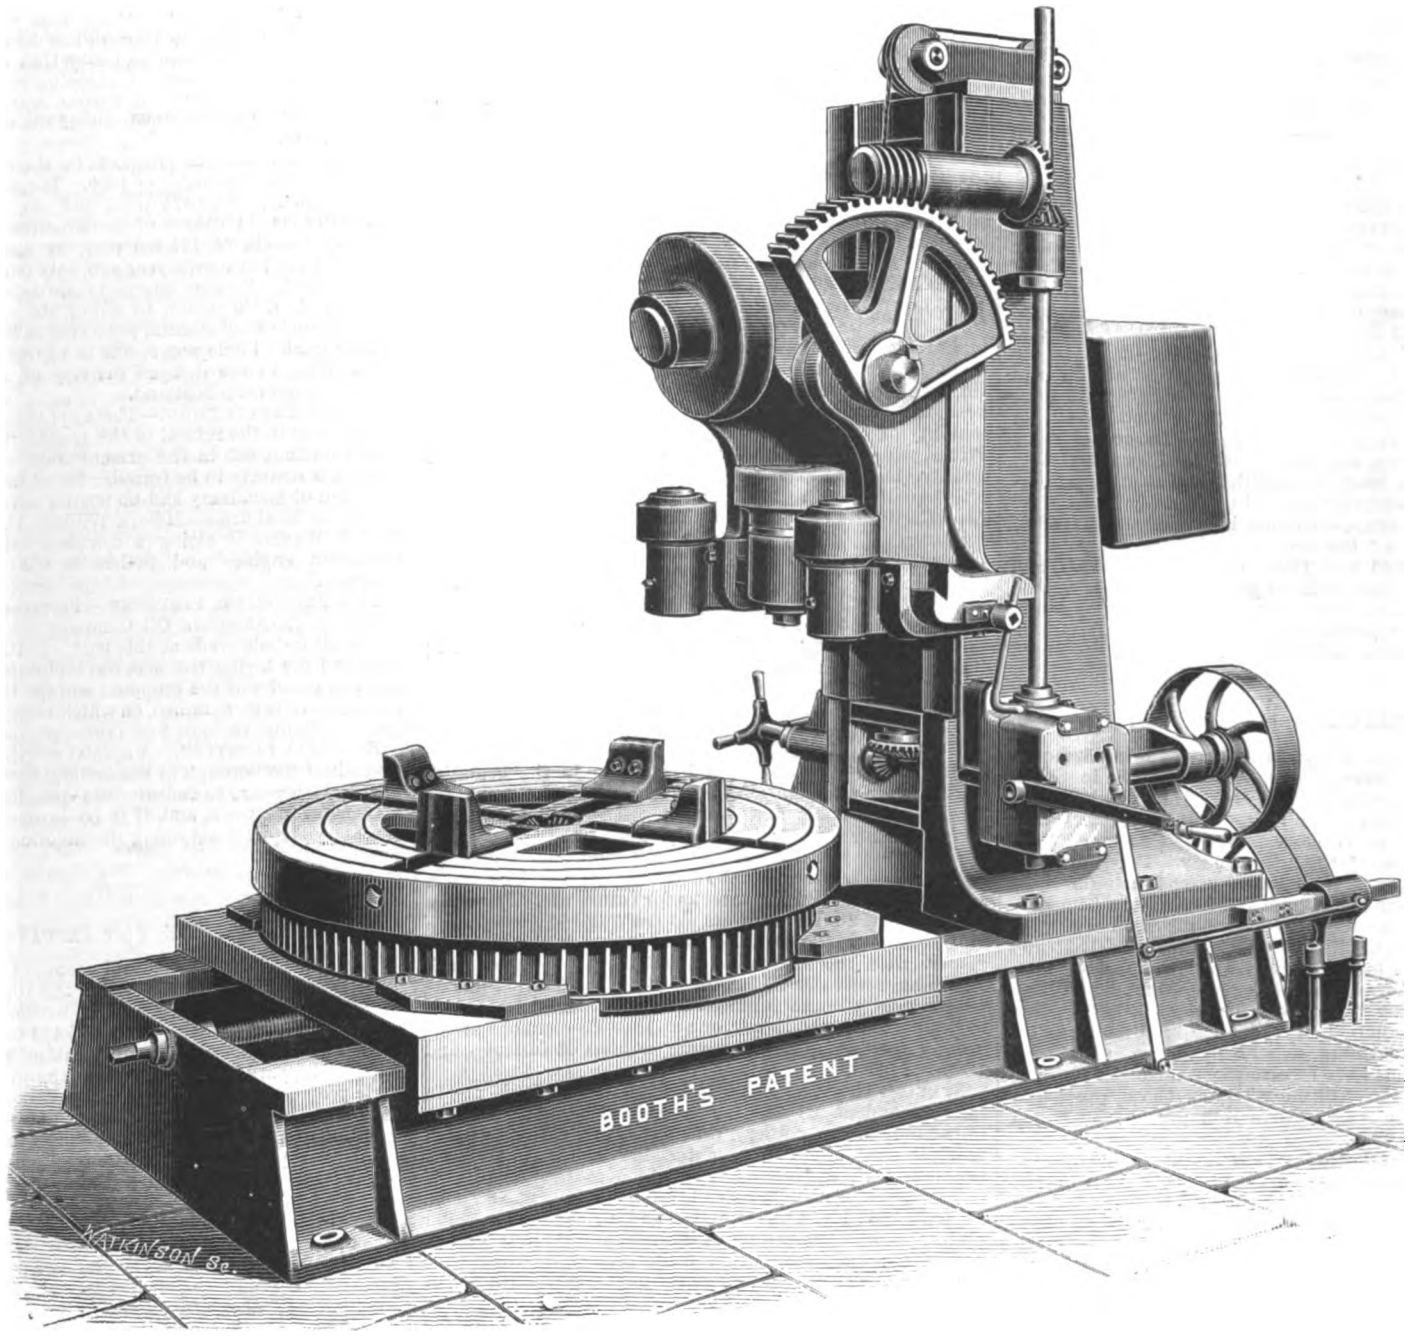
ELECTRIC LIGHTING.—A special meeting of the County Council of the borough of Sunderland has been summoned for the 16th prox., to consider the question of the electric lighting of the town, and, if it be so decided, to take the necessary steps for obtaining the sanction of the Board of Trade.

NEWCASTLE, 21st January, 1891.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock during the week ending the 10th inst. amounted to 93,022 tons, being a decrease, as compared with the corresponding week last year, of 15,439 tons.

SHIPBUILDING.—The severe weather tends greatly to impede shipyard work, and during the past few days very little progress has been made with contracts. An additional hindrance is found in the difficulty of procuring adequate supplies of material from the steel manufacturers, this cause of stoppage being more generally felt since the commencement of the Scotch railway strike. The present aspect of affairs is consequently very depressing, and in spite of the long spell of prosperity that has fallen to the lot of those connected with the trade, some sections of the workmen are now feeling the pinch of poverty. The only prospect of improvement lies in the advent of milder weather, and the settlement of the unfortunate dispute which prevents the conveyance of supplies from the steel making centres of Scotland, and it is to be hoped that these conditions will soon be brought about. The work now in the hands of builders is sufficient to keep the mass of the workmen employed for two or three months to come, if there were no exceptional impediments in the way of its progress, but no new orders are being received, and it seems probable that by midsummer more than half the building berths on the river will be empty.

ENGINEERING.—Marine engine works continue to be briskly employed, and for some time to come it is not likely that any very distinct indications of a falling off will be presented. The substitution of triple-expansion for compound engines in old steamers very materially assists in keeping the industry active, and will no doubt be the means of maintaining full work in the engine shops for some months after the shipyards have become slack. In the locomotive establishments business is also fairly good, and it is understood that some orders of importance are now being tendered for by local firms. Manufacturers of ships' pumps are well supplied with orders, and one or two firms that are concerned in the production of certain well-known engineering specialties are exceedingly busy.



MESSRS. GEO. ANGUS & CO.—At the annual meeting of shareholders, which was held on the 19th inst., the announcement was made that the business prospects of the company were excellent, and that the profits on the past year's working were sufficient to permit of a dividend of 10 per cent. being declared, after adding £7,000 to the reserve fund.

ELECTRIC LIGHTING.—Messrs. J. H. Holmes & Co. have obtained some further important contracts for both marine and land installations, and the great briskness which has existed at their establishment for many months past is likely to be maintained throughout the whole of the present year.

BOILER FLUE FLANGING MACHINE.

CONSTRUCTED BY MESSRS. GEORGE BOOTH & CO., ENGINEERS, CENTRAL IRON WORKS, HALIFAX.

GENERAL VIEW.

BOILER FLUE FLANGING MACHINE.

WE illustrate above a powerful machine, designed and constructed by Messrs. George Booth & Co., Central Iron Works, Halifax (for Messrs. Denny & Co., engineers and boilermakers, Dumbarton), for flanging marine boiler flues. It is capable of flanging flues of various sizes, from 1ft. 10in. to 4ft. 6in. diameter, by 1ft. 6in. to 4ft. 6in. deep, of mild steel plate ⅝in. thick. The flue to be flanged is placed upon the chuck plate and held secure by four gripping jaws, the top end of the flue being supported by two guide rollers, which are adjusted simultaneously to suit various diameters of flues. The chuck plate is rotated by powerful gearing, and the flanging roller is brought into contact with the flue by suitable power, which can be easily regulated by the hand lever shown on the front of the machine. This lever is in close connection with the belt fork lever, and is consequently under full control of the attendant. The machine is constructed in a substantial manner in order to withstand the rough usage of a boiler shop. It can bend a 4½in. flange on an "Adamson" pattern of flue at the rate of a flange per minute, each flange being formed at one heat. The material is not injured in any way, and the work done is superior to work found in hand-formed flanges. The object of the machine is to flange flues in short lengths in order to obtain the advantages of radial stiffness with the necessary longitudinal elasticity.

COMMERCIAL FORTUNES AND LAND PURCHASE.

THE steady decline in land values does not seem to have checked the desire of successful business men to become landowners. Each year the leading sales are to men who have themselves made fortunes or have inherited fortunes made in business. Last year was no exception to the rule. The largest single sale was that of the estate of Durris, in Aberdeenshire, to Mr. Baird, of Gartsherrie. The property, which extends to 17,000 acres, and has a rent roll of £9,700, had been withdrawn previously at £270,000. Among other Scotch sales were those of the Forest of Glentana, in Aberdeenshire, 29,000 acres, to Sir W. Cunliffe Brooks, for £120,000, and Kildermorie, in Ross-shire, to Mr. Walter Shoolbred, who has now acquired a deer forest of 45,000 acres. Mr. Frederick Colman last year bought Lord Egmont's place near Epsom, Nork Park, extending to 1,600 acres. This is not far distant from Gatton Park, which Mr. J. J. Colman had acquired from Lord Oxenbridge for £82,000 two years previously. Close at hand Mr. Boord, M.P., has settled down at Wakehurst, the historic home of the Dowager Marchioness of Downshire, which has been sold to him with an estate of 1,200 acres. Norbury Park, near Epsom, was transferred to Mr. Leopold Salomon for £75,000. Mr. Eckroyd was already a large owner of land in Cumberland before he added the 1,800 acres of Ormathwaite Hall to his possessions. He has now a stretch of nine miles' of fishing in the River Eden. The old estate of the Honeywoods, Chilton Park, near Hungerford, is the property of Sir William Pearce, who paid £80,000 for its 2,300 acres. The price paid by Mr. L. W. Adamson, of Park Works, Gateshead, for the 1,370 acres of Eglingham, in Northumberland, has not transpired, but the estate was bought in at the sale for £29,000. Mr. W. J. Joicey secured Sir James Mackenzie's place at Sunningdale, Ascot, for £40,000, just before the baronet's death. Mr. W. H. Smith continues his purchase of Lord Devon's lands that fringe Dartmoor. The chief feature of the Duke of Newcastle's important sale of his Worksop Manor estate in Nottinghamshire and Derbyshire was the purchase by Mr. John Robinson of the house and 1,644 acres for £35,000, with nearly as much again for the timber. The Thurgarton Priory estate, of almost equal value, had been acquired by Mr. Robinson two years previously. The Yorkshire territory owned by Mr. Samuel Cunliffe Lister, of Manningham Mills, now exceeds a million sterling in value. Recently he added to it the mineral estate of Ackton Hall, near Pontefract, the price paid for the 1,200 acres being £192,000. Selsdon Park, in Surrey, 563 acres, has become the property of Mr. Wm. Stevens. Finally, Mr. J. Spiller, of Westwood House, Droitwich, has bought Compton House, and 1,696 acres, near Stockbridge, in Hants. There were also many minor sales absorbing the estates of the old nobility and squirearchy.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 23RD JANUARY, 1891.

OUR NAVAL POLICY.

THE Naval Estimates will soon come before Parliament, and no doubt the whole subject of our naval policy will again be brought up for discussion. Last year the debate degenerated into a conversation on a few details, but in the interval the Report of the Commissioners on the Civil and Professional Administration of the Naval and Military Departments, and the relations of those Departments to each other and to the Treasury, has been presented to Parliament, and, moreover, many important discussions relating to our naval policy have taken place. At the time the Report appeared we made (see *Industries*, Vol. VIII., page 422) some reference to its most important points and mentioned its chief recommendations, but so far as we are aware nothing has been done to carry them into practice. The Report will necessarily receive attention in the next debate on the Navy Estimates. As we mentioned in our previous notice, the questions which are discussed in the Report are grouped under two principal heads, namely—(*a*) measures required to ensure closer administrative harmony between the naval and military services; (*b*) the internal administration of each of the two Departments and their respective relations to the Treasury. The first of these is the one which will receive most attention, not only because the second is less important, but also because during the past few years, as every one will admit, very great improvements have taken place in the administration of the various departments of the navy. The Commissioners stated that the first point which struck them in the consideration of the organisation of the army and navy was that though in action they must be to a large extent dependent on each other, and though in some of the arrangements necessary as a preparation for war they are absolutely dependent on the assistance of each other, little or no attempt has ever been made to establish settled and regular intercommunication or relations between them, or to secure that the establishments of one service should be determined with any reference to the requirements of the other. The Commissioners further report that no combined plan of operations for the defence of the Empire in any given contingency has ever been worked out or decided upon by the two Departments; that some of the questions connected with the defence of military ports abroad, and even of those at home, are still, after much departmental correspondence, in an unsettled condition; and that the best mode of garrisoning some of the distant coaling stations is also undecided. The Commissioners described this as an unsatisfactory and dangerous condition of affairs and one obviously requiring immediate remedy. Their proposals, however, did not excite much enthusiasm, the chief one being that there might be some advantages in the formation of a Naval and Military Council, which should probably be presided over by the Prime Minister, and consist of the Parliamentary heads of the two services with their professional advisers.

This is certainly a weak proposal after such an elaborate indictment of our present system, and has been severely criticised by naval and military authorities. It is, however, easier to criticise than to amend, and comparatively few definite proposals have been made for improving the present state of things. In a recent number of the *Nineteenth Century*, however, Lieutenant-General Sir W. F. D. Jervois makes some suggestions which are well worthy of careful consideration. He is of opinion that the failure of the Hartington Commission in its attempt to grapple with this difficult question is due mainly to one principal cause—namely, want of appreciation of the fact that Great Britain is primarily a naval power. According to Sir W. Jervois, the Hartington Commission placed the army and navy on the same pedestal, and, starting from this false assumption, failed, as might have been expected, to arrive at any conclusion which would square with actual facts. His view of the problem is this: Given, as they are at present, two mutually dependent services, so to organise them that they may efficiently perform each its proper function in the defence of the British Empire. The solution he puts forward amounts to this, that the navy must not be dependent on the army for the defence of its ports and coaling stations, nor must there be laid upon the Army Department the burden of finding garrisons for places which are held purely as foci for naval action. He thinks that the forces for the defence of naval stations, both at home and abroad, should be under the orders and control of the Navy Department. His aim is, in short, to have what he calls "Home Rule for the Navy," by making it self-sufficing and self-contained, and independent of the army for all its own requirements. He maintains that the navy should be absolutely responsible for its own efficiency in respect, not only of seagoing vessels, but of the various stations to which those vessels must resort for coal, refit, and repair. It would thus secure what it chiefly needs—unity of purpose and direction. This would involve the placing of the field artillery, the royal engineers employed on harbour defence, the submarine mining engineers—in fact, all engaged in harbour defence—under naval control. He even suggests that some portion, at least, of the militia and volunteers, in all places where they can take part in naval operations, should be comprehended within the same organisation. He strengthens his position by showing that in Germany the defence of the coast is entirely in the hands of the navy, and that in France, and the French colonies generally, the garrisons of sea fortresses consist of marine troops, under the orders of the Minister of Marine, and the defence of the coast is entrusted, not to military, but to naval officers. He further quotes the opinion of Lieutenant Colwell, of the Intelligence Department of the United States Navy, to the effect that "the coast defence of Great Britain is notably the most inefficient of any of the great European Powers." No doubt Sir William Jervois' proposals will come up for discussion in connection with the debates on the Naval Estimates, and we think them worthy of study.

The Commissioners considered not only the defence of the United Kingdom, its colonies, and dependencies, but also the protection of its commerce, supplies of food, and other necessaries. This part of the subject will, no doubt, be referred to in the Parliamentary discussion on the results of the autumn manœuvres last year. The present Board of Admiralty had been engaged in carrying on an extensive shipbuilding programme, but some of the Commissioners expressed an opinion that all those

Digitized by Google

causes which had made a strong navy necessary had operated, and were operating, at a greater rate than the programme of the last three years allowed for, and they were in favour of a still more extensive programme being undertaken.

A matter on which Sir George Tryon has strong opinions, and which is directly connected with naval policy, is that of the national insurance of our mercantile marine during a period of war. He thinks that, as the existence of the nation depends on free mercantile marine communication between the various ports, it is hard to call upon private individuals to provide, out of their own resources, what is necessary for the existence of the nation, and he contends that the nation ought to assist in meeting the expense. Stated shortly, Sir George's proposal is that the State, subject to certain conditions and regulations, should undertake to pay the cost of vessels and cargoes destroyed by the enemy. He urges that, on the outbreak of war, the premiums for marine insurance would rise to a great height—far, indeed, in excess of the real risk incurred—with the result that shipowners would become discouraged and feel inclined to lay up their vessels in port. This policy would not only diminish commerce, but place the supply of food and raw materials in the hands of neutrals, who, having to pay no large premium for war risks, would be placed in a position of great advantage. Such a scheme as this—although no doubt there are difficulties connected with it—would, in times of trouble, help us to maintain our industries, our commercial supremacy, and, above all, our food supplies, and is worthy of careful thought.

AMERICA AND THE SILVER QUESTION.

The current reports from the United States on the probable action of Congress with regard to silver are so contradictory, that it is impossible to form from them a trustworthy estimate of the probable future of silver. Although recent attempts of Congress to control the price of silver in the markets of the world cannot be said to have resulted successfully, and, therefore, indicate a certain want of foresight on the part of American financial politicians, it is impossible to lend credence to the report that it is likely that Congress will sanction the free coinage of silver in the United States while restricting the coinage to United States silver only. It is clear that such a proceeding, so far from lending support to silver, would not improbably result in further depression of the price, through a portion of the production apart from America being deprived of a market now existing there—at least partially. Meanwhile, the tendency seems to be in the direction of an advance in silver, although this may be checked by rumours, true or false, of United States legislation on the subject. While there is much to be said for a single Act of the Legislature having the effect of restoring the *status quo ante* demonetisation of silver, the frequent legislative pottering at the currency is unquestionably a mistake. We have been favoured with the following carefully prepared and, we believe, thoroughly reliable statistics bearing upon the present position of silver, with relative comments:—

TABLE I.

STATISTICAL POSITION OF SILVER AND PROBABLE EFFECT OF PROPOSED UNITED STATES LEGISLATION.

Production of Silver (in Ounces).

		United States.	Rest of World.	Total.
	1887	41,260,000	54,917,375	96,177,375
	1888	45,780,000	64,292,140	110,072,140
	1889	50,000,000	75,988,671	125,988,671
Estimates.	1890	53,000,000	83,000,000	136,000,000
Estimates.	1891	57,000,000	88,000,000	145,000,000

The estimates for 1890 and 1891 are, of course, to some extent, guesswork, but it will be seen that the ratio of increase has been put very considerably below that of the preceding years, though the stimulus to production afforded by the higher prices would seem to justify very much larger estimates.

The figures given in Table II. at the top of the next column show the disposition of silver, and are (approximately) summarised from the Report of Treasury to Congress in December, 1889, and refer to the previous year (1888):—

TABLE II.

	Ozs.
United States coinage and certificates	26,000,000
Arts and manufactures (for all the world—Soetbeer's estimates)	16,000,000
Subsidiary coinage, Europe and South America	17,000,000
China, India, and the East	45,000,000
Unaccounted for	6,000,000
Total for 1888 (as per Table I.)	110,000,000

If Congress enacts free coinage, restricted to home production, the United States will, of course, use up the whole of the silver they produce, and the balance of the world's production may be expected, on the above basis of distribution, to be disposed of as shown in

TABLE III.

		Ozs.
Arts and manufactures (as before) Subsidiary coinage Unaccounted for	As in Table II.	39,000,000
Leaving for India and the East		49,000,000
Total production for 1891 outside United States, as per Table I.		88,000,000

Therefore, India and the East will have to absorb, even on the extremely moderate estimate of production given in Table I., 49,000,000oz. in 1891, against 45,000,000oz. in 1888, although silver and the Eastern exchanges now are 10 to 12 per cent. higher than they were then. This seems to indicate that silver and the exchange must come down considerably in order to admit of the additional absorption. If, however, Congress passes an Act increasing Treasury purchases to (say) 6,000,000oz. monthly, the effect on silver generally would probably be more favourable, because then the Treasury purchases would not only absorb the whole of the home production, but also some 15 million ounces more (on the basis of Table I.). It must, however, be remembered that there is a heavy accumulation of stock in the United States, computed at 12 to 15 million ounces (visible and invisible), so that any rise in price which might be occasioned by the passing of such a measure would probably not last long.

It was announced last October that Austria had decided to convert into gold at the earliest favourable opportunity 60 million florins out of the 190 millions she holds. If this were done, it would add 20 million ounces to the world's supply of silver. On the other hand, as regards silver securities, such as rupee paper, the extreme cheapness of money and scarcity of first-class securities is one favourable feature, and another is that the value of silver will probably be to some extent sustained speculatively by the expectation that the next Congress will enact unlimited free coinage.

These conclusions appear sound. There is, however, the not very remote probability that Congress, disappointed at the result of its past legislation on the silver question, will leave the matter alone for a year, and trust to the chapter of accidents to bring about a change in the market price of silver which would relieve the United States of the necessity of independent silver legislation. The probability, on the other hand, of France taking some step in the near future is certainly to be reckoned with in any comprehensive view of the situation.

THE SCOTTISH RAILWAY STRIKE.

Although the goods and mineral traffic is being partially grappled with by the railway companies, this is only being done at the expense of the passenger traffic. The number of men still on strike, in spite of deflections from their ranks, is still sufficient to prevent due performance of the public service. The shipbuilding yards are now all working, though at some of them the stock of steel is being so rapidly exhausted that they cannot go on much longer without supplies from the works. These are all stopped excepting the Clydesdale, which has succeeded in maintaining its supplies of fuel and iron. The difficulty of getting material conveyed is so great that some of the boiler makers are at a complete standstill for want of plates.

To all attempts at conciliation by the men the directors have given the unvarying reply, "Return, and we will consider your grievances." The men regard this as too vague. The deadlock thus remains in the fifth week of the strike, to the almost intolerable embarrassment of the public, and specially of the industrial community. It is necessary to explain that the Glasgow and South-Western Company's men returned to their work some time ago, that a considerable proportion of the Caledonian men have returned, and that now, as at the beginning of the struggle, the chief brunt of it falls upon the North British Railway. The returns of these companies show that the proportion of rolling stock to mileage is largest in the first case, smaller in the second, and smallest in the third. It is fairly clear, therefore, that the real cause of the crisis and of the prolongation of it, is the insufficiency of the rolling stock of the North British Company. The directors are apparently attempting to work their business with insufficient plant and with too small a capital. If the company gave orders for a hundred additional engines, and raised the capital necessary to pay for them, the service would be vastly improved, and the chronic state of discontent, both of the servants and of the public, be ended.

THE SKILLED LABOUR MARKET.

According to the Board of Trade Journal, the state of the skilled labour market during the past month affords little indication of the general labour interest of the kingdom. Several weeks of severe weather have seriously affected the indoor industries by interfering with the means of transport of the raw material. Building and other outdoor trades have suffered most severely from the severity of the weather. The number of strikes during the past month was sixty, which is one less than in the previous month, and of these fifteen were in the cotton trade. The railway strikes in Scotland have affected a large number of workmen. Of the twenty-two trade unions of skilled operatives which have sent in returns as to the state of their respective industries, a few show a slight improvement, but the majority show a marked falling off consequent on the causes already referred to. The total membership of these societies is stated at 239,960, and of these 7,302 are returned as unemployed. This is a proportion of 3·05 per cent., as against 2·4 in the month preceding. As compared with the corresponding period of previous years, it may be said that in January, 1890, the percentage of men out of work in these trades was 1·7; in January, 1889, 3·3; January, 1888, 6·9; and in January, 1887, 8·7. The trades showing most improvement are the cotton-spinning and shipbuilding trades, the percentage of those out of work in the last-named industry having improved during the month from 5·76 to 4·27. Most of the other trades show worse results, but in no case can the change be pronounced serious when all things are considered.

TREATY REVISION IN JAPAN.

The question of treaty revision in Japan, to which we have frequently referred, has become complicated by considerations of party politics and sectional opinions, and these will add immensely to the difficulty of settlement. As we have on a previous occasion pointed out, the question might have been settled some years ago with comparative ease, in a manner which would have prevented it being raised for a considerable time, for then the foreign Powers had only to deal with a comparatively despotic Government. Now it has to deal with a representative Government which is criticised by a public press, and which is thus doubly bound to respect public opinion. It is stated by the foreign press in Japan that the recent proposals of the Government are for the purpose of conciliating the patriotic party in the country, and evoking the opinion of the foreign residents, which, in the open ports at least, is unanimously and decidedly against the proposals. It is not within our province to enter into the consideration of either the personal or political questions involved, but we have no hesitation in saying, after considerable personal knowledge of the country and the people, that the present state of affairs is a grave injustice to Japan and an injury to the foreign trade of the country. During the past twenty years the Japanese have made so much progress in every way that it is only right that they should expect a considerable relaxation of arrangements which were made under a totally different state of affairs. We trust that some method will soon be found to bring a change about.

EFFECTS OF THE McKINLEY ACT.

According to a statement made by a correspondent of the *Times* with reference to the working of the McKinley Act during the past three months, the working people of the United States are worse off than before the change in the duties. In many cases there has been a decrease in wages, whilst there has been a rise in the price of nearly all the necessaries of life. In some manufactures there has been an increase in the price of the product without any increase in the workers' wages. The Furnacemen's Union, the Journeymen Plumbers' Union, and the Typefounders' Union all report that there has been a reduction of wages, whilst, in other instances, such as that of the Manhattan Brass Works

Digitized by Google

and lace and mantle manufactures, the reduction of wages has resulted in strikes, which have been generally unsuccessful. The workpeople of several firms engaged in the cigar trade struck work on their wages being reduced, and in other trades, where the men have struck, their places have been filled by foreigners. The workers in the silk, upholstery, woollen, and cotton trades have also suffered a reduction of wages, and the restriction of production by some manufacturers has still further injured the workers. The goldbeaters alone have secured an advance of wages through the passing of the Act.

THE LATE MR. COSMO INNES BURTON.

A recent China mail has brought news of the death of Mr. Cosmo Innes Burton, who was appointed last year to the Professorship of Chemistry at the new Technical Institute of Shanghai. His death at the age of twenty-eight has excited feelings of regret among fellow workers in this country, who regarded him as one of the most original of the younger generation of chemists.

Mr. Burton's father was Mr. John Hill Burton, the well-known Scottish historian. That his intellectual inheritance, however, was scientific, not literary, was early apparent, for as a boy he worked in the chemical laboratory which he and his elder brother—now Professor of Sanitary Engineering in the University of Tokio—fitted up for themselves. After graduating in Edinburgh Mr. Burton became assistant to Dr. Japp, now Professor of Chemistry at Aberdeen, and, in conjunction with him, contributed four memoirs to the Journal of the Chemical Society, embodying the results of extensive researches in the department of organic chemistry. His interests in chemistry, however, were essentially of a practical nature. He was interested in social reforms of every kind, and eagerly embraced the opportunity offered to him by the Town Council of Edinburgh of examining the air of public buildings in that city. He made a careful chemical and biological investigation of the air of the chief schools and theatres of the city, and drew up an exhaustive report on the subject.

He was profoundly interested in both the technical and philosophic aspects of chemical science. One of his investigations, the subject of which was the heat produced by the compression of pure solid and liquid substances, was pretty far advanced before he left for China. His friend, Mr. W. Marshall, in conjunction with whom a large part of the work was carried out, will shortly publish the results of the research.

Mr. Burton received last spring his appointment in China, and proceeded to Shanghai, where he arrived in the end of July. A letter written by him in the beginning of October was full of hope and enthusiasm about his work. Within a month of the date of the letter he was cut down by an attack of malignant small-pox after two or three days' illness.

THE LATE BARON HAUSSMANN.

The death of Baron Haussmann, in his eighty-second year, which we briefly announced last week, removes from French society a well-known figure, who, as Prefect of the Seine under the Empire, did so much to transform Paris from a mediæval to a modern city. Beginning life in the office of a notary, he worked his way to the Bar, and from that, through various grades of office, to the Prefecture of the Seine in the year 1853, and it was in this position that he did the most important part of his life's work. The chief feature in the domestic policy of Napoleon the Third was the transformation of the capital. A glance at the map of Paris shows that in its general plan it differs from most modern cities chiefly in the fact that, instead of being laid out in rectangles, its main thoroughfares radiate from a few central points, an arrangement which is admirably adapted for the treatment of insurgent masses, for a few cannon placed at each point could sweep the streets with ease. One of the chief industries of Paris has for a long time been the entertainment of visitors, and it has met the want of a city of pleasure for those who have superfluous wealth—a want which was beginning to be more widely felt about the time of Haussmann's appointment. Every franc invested in improvements brought a certain return to the city, and helped to increase its trade. During the seventeen years of Haussmann's reign as Prefect of the Seine, he opened 200 new thoroughfares, built 14 bridges and 400 kilometres of sewers, and laid down 1,200 kilometres of main piping for the water supply. He built 241 new public buildings of different kinds, and covered 80 hectares with markets and slaughter-houses. He made in some of the worst parts of the city many new thoroughfares, and in other places he erected splendid rows of palaces ornamented by public gardens. The woods of Vincennes and of Boulogne were transformed into splendid parks, and Montceau was made a perfect gem of landscape gardening.

The cost of all this was, of course, enormous—more than two milliards of francs, or close upon £85,000,000, of which about one-half was raised by loan, and the rest defrayed out of ordinary municipal revenues. The interest to be paid per annum was about 67,000,000fr., reducible to 57,000,000fr. as the annuities fell in. On the other hand, the revenue rose by leaps and bounds, and in the last year of his tenure of office not only met all charges, but left about a million and a half sterling for new undertakings. All this was done without fresh taxation, and the present high rates on the citizens of Paris arise, not from Haussmann's operations, but from the expenses of the war and of the Commune.

Letters to the Editor.

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—I have read with much interest your recent articles by Mr. Thwaite on the above subject, and, whilst congratulating him in suggesting a possible solution for the remedy of London's great plague, should like to point out a few of the difficulties which his scheme would have to surmount.

In all radical changes—unfortunately, perhaps—the main question to be decided is one of cost, and I think that it is mainly in the estimate of the economic value of the scheme that criticism on Mr. Thwaite's suggestion will be directed. Even if we admit with him that gaseous fuel has economic advantages which render it superior to all other forms of heat, the large amount of capital required to convert existing plant adapted for burning coal and coke into suitable gas stoves is sufficient to cause many people to restrain from making any change in their present forms of heating. Not only is this the case, but we have, I believe, yet to discover what form of domestic gas stove is best adapted to the heating of rooms, and Mr. Thwaite gives us no information in this direction.

It is true that the gas companies for many years past have been endeavouring, by lectures and demonstrations, to educate their customers to the advantages which may be derived from cooking by gas, but there are few stoves which can be said to fulfil all the requirements of home use.

Mr. Thwaite should, in fairness to his scheme, add the cost of converting in each house the existing hearths into the best form of gaseous stove, and add thereto the loss of capital which would be necessarily entailed by a universal adoption of the new system of heating. I think that his alternative scheme will commend itself to most of your readers, as such a system would admit of gradual development, and make it possible for builders to design and construct new houses with a dual system of pipes for both lighting and heating purposes. Although the recent trials of incandescent gas lighting at Harrogate and elsewhere have not been so satisfactory as advocates of this system would like, yet it by no means follows that we may not have a perfected system of rendering a heat-giving gas available for lighting purposes as well, and, if such a system be devised, a supply of heating gas would be still more desirable for the poorer districts, where electric lighting is not likely to be sufficiently economical for general use for many years.

The discussion which Mr. Thwaite's articles deserve should certainly lead to some immediate steps being taken to induce the authorities who are appointed to discharge the duties of carrying out the development of our big city to give an earnest consideration to the suggestions which Mr. Thwaite has put forward in his able articles.

Yours, &c.,
Cockney.

London, 19th January, 1891.

To the Editor of "Industries."

Sir,—The article by Mr. Thwaite in your last week's issue suggests such a complete revolution in our present system of heating that it seems necessary to consider whether we cannot effect such a desirable change in some simpler way.

Mr. Thwaite, whilst striking out an original line for dealing with this evil, seems to ignore the steps which are being taken by others towards achieving the same object, and, although we may admire him for his originality in proposing so bold a scheme, it would have been better if he had given reasons for assuming that the present efforts will not be fruitful of any permanent results. The committee which is at present at work in Manchester is doing good work in testing smoke-preventing appliances, and their report, which is to include not only "a comparison of the different methods of burning coal smokelessly," but is to be extended to those methods of consuming coal where the fuel is first converted into gas, and the gas so produced burned in the furnaces, will give a basis from which future operations may satisfactorily spring.

Mr. Thwaite, by assuming that gaseous fuel is the only way out of the difficulty, has forgotten that improvements are gradually evolved out of existing systems, and that radical changes are seldom adopted on a large scale without a long period of trial on a small scale.

The Alkali Inspector, in his last annual report, referred to the satisfactory nature of the gas-producing arrangements of Messrs. Brunner, Mond, & Co., in Cheshire, where not only is a smokeless gas economically employed in the place of the ordinary system of coal burning, but an important bye-product in the form of ammonia—equal to 66lb. of sulphate for every ton of coal—is obtained. This experiment, together with the employment of natural gas in Pittsburgh, does certainly tend to support Mr. Thwaite's views. The conditions of success for domestic heating are, however, entirely different, as gaseous fuel seems to be only adopted for local heating, and the gas stoves and other appliances at present in use have not been very acceptable to the public. If Mr. Thwaite had been able to demonstrate the advantages in a changeable climate such as London of a system of hot water or hot air heating and ventilation, in which his gaseous fuel could be consumed in the basement of a dwelling-house, and thus be a source of heat for the whole building, then his scheme would have been more complete, but until he tells us how he intends to use his gaseous fuel as a source of domestic heating I must regard his solution as impracticable and Utopian.

Yours, &c.,
R. S.

London, 20th January, 1891.

IMPROVEMENTS IN THE MANUFACTURE OF NITRIC ACID.

To the Editor of "Industries."

Sir,—I am sorry that I cannot give your correspondent, Mr. Blount, such definite information as he wants, as to the cost of erection of a nitric acid factory, both on the old system and on my new one, since I cannot control the figures given at random by others. I have built several factories, both on the old and on my system, and my statements as to relative cost were based on this experience, and from the personal knowledge of the arrangement of over a score of factories.

It will, of course, be patent to every expert that factories may be built in very different ways, and that their actual cost must, in consequence, vary considerably. Thus, in the case of a factory where perfect working is considered of secondary importance to cost of plant, a wooden shed, and imperfect means of condensing the last traces of fumes (providing there is no Alkali Act to interfere with such practice), may be erected at a considerably less cost than a properly arranged and equipped factory, although the difference can never be so great as to reduce the cost to £1,500 for a daily output of 35 cwt. of strong acid. But it was not such a woodshed makeshift that I had in my mind. I compared a high-class factory on the old system with a high-class one on my system, and then the saving must be at least 60 per cent., since my system requires two-thirds less building and one-half the number of retorts and batteries required for the best old system.

To give Mr. Blount an exact idea, I may mention that an estimate that I have recently given for a factory to produce 1,500 tons of strong acid yearly, solidly built in brick and filled with the best appliances, to comply with regulations quite as strict as the English Alkali Act, amounts to about £3,200, including a brick chimney shaft 80ft. high.

Yours, &c.,
Oscar Guttmann.

Dunster House, Mark Lane, E.C.,
17th January, 1891.

IS THE STUDY OF THERMODYNAMICS OF USE TO ENGINEERS?

To the Editor of "Industries."

Sir,—I have read with much interest "Student's" letter, under the above heading, in your issue of the 9th inst. That such a question as that under discussion should be answered in the negative, can, in my opinion, only be due to a thorough misconception of the true relations in which theory and practice stand to one another. Generally speaking, in a certain sense, practice—whether it be the practice of nature or of man—must precede theory. Every theory, however complete and far-reaching may be its applications, must, in order to have any value at all, be based, in the first instance, on observed phenomena, of which there can be no ultimate explanation. A good instance of this is the law of gravity, the fundamental expression of which is the result of observation, and in so far empirical. I need scarcely remark that I should apply the term "result of observation" to a theory which had been in the first instance conjectural, but was confirmed subsequently by experiment.

Theory is simply the systematic expression, in the first instance, of the laws which experience has shown to apply to phenomena. If true and general in its character, it will always be found capable of extension beyond the original limits of observation, and in this way is often prophetic.

Descending from the general to the special, and confining our attention to the theory of thermodynamics, what do we find? The theory of heat, even as formulated twenty years ago, contained the germs necessary for the development of a complete theory of the steam engine; that it was not practically applied appears to me to be, not the fault of the theory or its originators, but of the engineers who were incapable of appreciating it and seeing whither it tended! A reproach frequently hurled at the ordinary text-books on the steam engine is that they assume, for theoretical purposes, a condition of things in the cylinder of a steam engine which has no existence in reality—namely, that the walls are non-conducting. On the strength of this it is asserted that their teachings have no value whatever, and are even misleading. This is simply absurd. In elementary applied mechanics problems are generally studied, in the first instance, on the assumption that there is no friction, yet I venture to think that no one would assert, on this account, that the study of such problems was useless, and only to the least intelligent of students could it possibly be misleading.

At the present day the study of thermodynamics in its broadest sense is as essential to an engineer, who has to do with steam or other heat engines, as is a knowledge of geometry and trigonometry to a surveyor. If the interest taken in the subject by the leading men in the engineering profession is any evidence of its utility, then let your correspondent "Student" attend a meeting of either the Institution of Civil Engineers or the Institution of Mechanical Engineers, when any paper on steam engine performance or a kindred subject is under discussion, and I think he will be amply convinced. For the man ignorant of thermodynamics, a great part of such a discussion would be mere unmeaning gibberish. It is not merely or mainly the professors, for whom your contemporary, *The Engineer*, has such unbounded contempt, whose voices are to be heard at these meetings discoursing of adiabatic, isothermal, and saturation curves, standards of

Digitized by Google

efficiency, initial condensation, and the like, but those engaged in the manufacture of steam engines, locomotive superintendents, and marine engineers.

Speaking from my own experience, I have no hesitation in saying that every man occupied with the design of steam, gas, hot air engines, or air-compressers should have a thorough knowledge of thermodynamics. Such a knowledge, even if it did nothing further, would, for example, at least save him from the not uncommon mistake of imagining that there is a margin of about 90 per cent. for economising in the best steam engines and boilers and from wasting time on impossible schemes for this object. Half an hour's calculation will often prevent the expenditure of days, or even weeks, of fruitless labour, which, in the absence of the necessary theoretical knowledge, would have been certainly undertaken through ignorance of its futility.

On no subject, I believe, is there a greater confusion of ideas than on the purpose and scope of technical education. It is very usual to hear so-called practical engineers speak disparagingly of the capacity of youths trained in technical colleges. They seem to imagine that such institutions, if their existence is to be justified, ought to turn out ready-made engineers, and because they find that is not the case sneer at "theory." The fact of the matter is that nowadays, in order to qualify for his profession, the young engineer requires theoretical training *in addition to* and *not as a substitute for* the practical discipline of former days.

Yours, &c.,
G. R. Bodmer.

London, 20th January, 1891.

Legal Proceedings.

BRITISH TANNING COMPANY *v.* GROTH.

This was an action tried before Mr. Justice Romer and was brought by the assignees of Messrs. Worms and Babé's patent, No. 9515 of 1887, to restrain an alleged infringement, and to recover damages in respect thereof. For the plaintiff the Attorney-General appeared, with Mr. Farwell and Mr. Gregson; for the defendant, Mr. J. Fletcher Moulton, Q.C., and Mr. Oswald.

The patent covers a new process of tanning, which has proved to be extraordinarily successful, and has effected a reduction in the time consumed in the process from six or eight months to no more than as many days. The process consists essentially in causing a current of electricity to pass through the tanning liquid and the hides immersed in it, and at the same time in maintaining the contents of the vat in a state of mechanical agitation. The agitation prevents the formation of a film of exhausted liquid upon the surface of the partly treated hides, and secures uniformity of composition throughout the tanning medium. The passage of the electric current facilitates the process of osmose, by which the tanning agents are conveyed into the interior of the hides.

The Attorney-General, in opening the case for the plaintiff, argued that the patentee had been the first to disclose the process of treating hides simultaneously by mechanical agitation and the electric current. The particular method of embodying this principle which he had described consisted in enclosing the hides and tanning liquor in a rotary drum mounted upon a horizontal axis. The drum would be about one half full of liquor, and the liquor would contain the hides. The current was introduced by means of electrodes mounted on the interior of the drum in contact with the liquid, and the circuit completed through the liquid. He contended that this was to be regarded as a type of the class of tanning appliances in which the treatment of the hides by the combination of mechanical rotation and the electrical current simultaneously applied was to be found, and that a proper construction of the patent would enable the patentee to assert rights in respect of all such appliances. Upon this view of the patent he showed that the apparatus used by the defendant would be an infringement. In the defendant's process the hides are stretched upon a frame which turns upon a vertical axis within a tanning vat, which may be, but is not necessarily, a circular stationary drum. The electric current is introduced by means of metallic electrodes disposed somewhat differently from the plaintiff's, but substantially equivalent to them. There is here, then, a rotation of the hides in the tanning liquor for the purpose of keeping that portion of the liquor which is in contact with the skins constantly refreshed, and an electric current employed to promote osmose. The differences introduced by employing a rotating frame turning on a vertical axis within the vat, instead of a drum rotating on a horizontal axis and containing the whole charge of liquor and hides, were, he contended, merely colourable differences, and did not take the process out of the category of infringements.

The validity of the patent sued upon had been called in question on one ground only—namely, that of the publication of the invention within the realm through the medium of an abstract of the patentees' American patent, which was received at the Patent Office before the date of the English application. The Attorney-General admitted that this prior publication would be sufficient to destroy the patent if it were not protected by the Patent Act, but he contended that in the circumstances of this case the publication could not operate to injure the patent. He relied upon section 103, which provides that in the case of an application for a patent made by the patentee in a foreign State of the invention sought to be protected, if that State be one with which the Government of this country has entered into any arrangement for the mutual protection of inventions, the applicant shall be entitled to a patent for his invention in priority to other applicants, and that such patent shall have the same date as the date of the protection obtained in such foreign State, provided that the application be made within seven months from the application in the foreign State. The section further provides that the publication or use of the invention within the realm during such seven months shall not invalidate the patent. The original patent in this case was taken out in France, and with the French Government such a convention as is contemplated by the statute had been concluded on the 17th March, 1884. A French patentee coming for an English patent in 1887 was entitled to his original French date if he applied within seven months, a period which would cover the actual date of the present application. The Attorney-General was constrained to admit that this patent had not in fact got the French date, but he argued that the claim in the statute was only directory, and that it was the duty of the Patent Office to give to every grant its proper date. That if the office had failed of its duty in this instance, the effect could only be to abridge the term of the patent, not to render the grant invalid, and he met the point that it was for the patentee to see that he got the right date, by explaining that at the time when this application was made no form had been devised which was strictly applicable to the case of a foreign patentee. On the contrary, every application was required to be made in the common form scheduled to the Act, and this form made no reference to foreign patents.

He called in support of his case Mr. Wm. Crookes, F.R.S., Professor Sylvanus Thompson, Professor George Forbes, Mr. James Swinburne, and Mr. John Thomas Blackmore, the last named being a practical tanner. The evidence which they gave was directed to support the Attorney-General's opening statement, but Mr. Moulton, in cross-examination, elicited admissions that the mechanical treatment of hides during tanning in a revolving drum quite apart from electricity was a well-known process at the date of the patentee's application, and that this treatment had for some purposes distinct advantages over other methods of mechanical treatment. In particular it was admitted that, as compared with the defendant's process of stretching the hides upon a frame, the method of causing them to roll upon the interior face of a rotating drum produced a bending of the hides upon themselves and a rubbing upon one another, which were important items in the treatment. They greatly increase the suppleness of the resulting leather, and they also occasion a rise of temperature.

Mr. Moulton, for the defence, called Mr. A. Wilson, a practical tanner, Dr. S. Rideal, and Mr. A. P. Trotter. Their evidence was directed to emphasise the effect of the admissions already obtained from the plaintiff's witnesses, that the method of tanning in a rotating drum was a known method of treating hides at the date of the patent, and that it possessed distinct advantages over other methods of mechanical treatment, which led to its preferential adoption in the preparation of certain leathers; that in these respects it was distinct from the defendant's process, and that this particular process would be understood to be indicated by the language used in the specification. Upon these materials Mr. Moulton submitted his case. He argued that the process "substantially as described," which the patentee had claimed, was not the broad method of applying mechanical agitation and an electric current simultaneously, but the more narrowly defined mechanical process, of which the rotating drum forms an essential feature, and in support of this contention he relied, not only on the terms of the English specification, but also on the still more explicit language of the French specifications, which he was able to use for this reason: it was essential to the plaintiff's success that he should assert that the French patent and the English patent were for the same invention, as otherwise the Convention would not get rid of the prior publication of the American abstract. But, if so, either the one or the other might be read to ascertain wherein the invention consists. Upon the point of law he argued that, as it is certain that under existing rules the foreign patentee has the option of taking an ante-dated patent under the Convention, or an ordinary patent without regard to the Convention, whichever he might consider more advantageous, it must have been so from the first, otherwise it would follow that the rights of the foreign patentee had been abridged by the statute and limited to the conventional patent, and only restored by the new rules when made. Therefore the patentees must be taken to have exercised a choice when they obtained their British grant, and the date is conclusive evidence against them as to what their choice was.

Mr. Farwell replied for the plaintiff, and Mr. Justice Romer gave judgment in favour of the defendant on both points. In so doing, he remarked that Subsection 2 of Section 103 of the Patent Act must be read as a part of the whole section. It was not intended to extend the rights of a patentee taking an ordinary patent. Although no special form of application had been devised at the date of this patent, the date is, nevertheless, conclusive. If there had been a mistake it was the patentee's fault, or, if not his fault, then his misfortune. Upon the point of infringement his decision turned entirely upon the construction of the specification, and he thought that the true construction was the narrower one for which the defendant had contended—not the broader for which the plaintiff had argued. Upon this view there was no infringement, and his judgment went accordingly.

The practical questions agitated in this case are of the greatest interest and importance, since extraordinary results, as above mentioned, have been obtained by applying electricity to the tanning process in the way now disclosed. The technical questions also are of no slight importance. The point so much discussed about the effect of the Convention is not likely to affect many patents, since the difficulty can hardly arise, now that a special form of application has been provided for the use of a foreign patentee. But the case illustrates afresh the capital importance of properly drawn claims. So far as the evidence tendered shows, there was no reason at all why Messrs. Worms and Babé should not, in 1887, have obtained protection for the broad principle of applying an electric current to hides undergoing the tanning process in any form of apparatus which kept them in a state of mechanical agitation. They elected to patent one form of such apparatus, that which they considered best for their purpose, with the consequence that the idea which they were undoubtedly the first to embody in an invention became thereupon common property, and at the service of every inventor ingenious enough to devise a novel mode of applying it.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.*

Kinetic Theory of Gases.—Matter at its ultimate degree of extension is conjectured to be not continuous, but granular. With speculations as to the constitution of liquid and solid matter I need not trouble you, but will proceed at once to the third or gaseous state of matter.

The kinetic theory of gases teaches that the constituent molecules dart in every possible direction with great but continually varying velocities, coming almost ceaselessly in mutual collision with each other. The distance each molecule traverses without hitting another molecule is known as its *free path*; the average distance traversed without collision by the whole number of molecules of a gas at any given pressure and temperature is called the *mean free path*. The molecules exert pressure in all directions, and are only restrained by gravitation from dissipating themselves into space. In ordinary gases the length of the mean free path of the molecules is exceedingly small compared with the dimensions of the vessel, and the properties we then observe are such as constitute the ordinary gaseous state of matter, which depend upon constant collisions. But if we greatly reduce the number of molecules in a given extent of space the free path of the molecules under electric impulse is so long that the number of their mutual collisions in any given time in comparison with the number of times they fail to collide may be disregarded. Hence, the average molecule can carry out its own motions without interference. When the mean free path becomes comparable to the dimensions of the containing vessel, the attributes which constitute gaseity shrink to a minimum, the matter attains the ultra-gaseous or "radiant" state, and we arrive at a condition where molecular motions under electrical impulse can easily be studied.

The mean free path of the molecules of a gas increases so rapidly with progressive exhaustion, that whilst that of the molecules of air at the ordinary pressure is only $\frac{1}{10000}$th of a millimetre, at an exhaustion of a hundred-millionth of an atmosphere, the mean free path will be about 30ft.

In discussing the motions of molecules we have to distinguish the *free* path from the *mean free path*. Nothing is yet known of the *absolute* length of the free path nor of the *absolute* velocity of a molecule. For anything we can prove to the contrary, these values may vary almost from zero to infinity. We can deal only with the *mean* free path and the *mean* velocity.

The Passage of Electricity through Rarefied Gas.—The various phenomena presented when an induction spark is made to pass through a gas at different degrees of exhaustion point to a modified condition of the matter at the highest exhaustions. Here is a slightly exhausted tube (Fig. 1), like the first in the series just exhibited (75 mm.), the induction spark passes from one end to the other, A B, and the luminous discharge is seen as a line of light, acting as a flexible conductor. Under the tube I have an electromagnet C, and on making contact the line of light dips in the centre down to the poles of the magnet, and then rising again proceeds in a straight line. On reversing the current the line of light curves upwards. Notice that the action of the magnet in this case is only local.

* Abstract of Presidential Address given by Mr. William Crookes, F.R.S., before the Institution of Electrical Engineers on the 15th inst.

Digitized by Google

In a highly exhausted tube the action is quite otherwise. Such a tube is before you (Fig. 2), and in it I have carried the exhaustion to a high point (0·1 mm.). I pass the induction current and you perceive the electrified molecules, like the line of light in the first tube, also move in straight lines, and make their path apparent by impinging on a phosphorescent screen D E. If, however, I submit them to the action of a magnet C, their behaviour is different. The line dips down to F, but does *not* recover itself.

FIG. 1.—P = 75 MM.

It seems that in the tube first shown we have to do with the average behaviour of the molecules of gas in its totality. In the second case, where the gas has been greatly attenuated, we are merely concerned with the behaviour of the individual molecules of which it was originally composed.

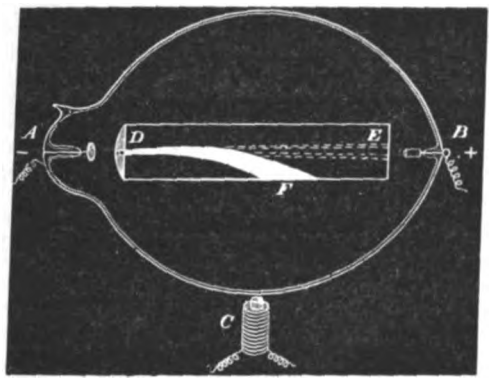

FIG. 2.—P = 0·1 MM.

The Stratified Discharge.—When the gas is rarer than is necessary to give the flexible line of light, as shown in the first experiment, the luminosity is plainly discontinuous, or, as it is termed, stratified.

A very good illustration of this fact may be taken from the moving crowd in any much frequented street, say, Fleet Street. If at some time, when the stream of traffic runs almost equally in both directions, we take our stand at a window from which we can overlook the passing crowd, we shall notice that the throng on the footway is not uniformly distributed, but is made up of knots, we might almost say blocks, interrupted by spaces which are comparatively open. We may easily conceive in what manner these knots or groups are formed. Some few persons walking rather more slowly than the average rate slightly retard the movements of others whether travelling in the same or in an opposite direction. Thus a temporary obstruction is created. The passengers behind catch up to the block and increase it, and those in front, passing on unchecked at their former rate, leave a comparatively vacant space. If a crowd is moving all in the same direction the formation of these groups becomes more distinct. With vehicles in crowded streets, the result, as everyone may have remarked, will be the same. Hence mere differences in speed suffice to resolve a multitude of passengers into alternating gaps and knots.

Instead of observing moving men and women, suppose we experiment on little particles of some substance, such as sand, approximately equal in size. If we mix the particles with water in a horizontal tube and set them in rhythmical agitation, we shall see very similar results, the powder sorting itself with regularity into alternate heaps and blank spaces.

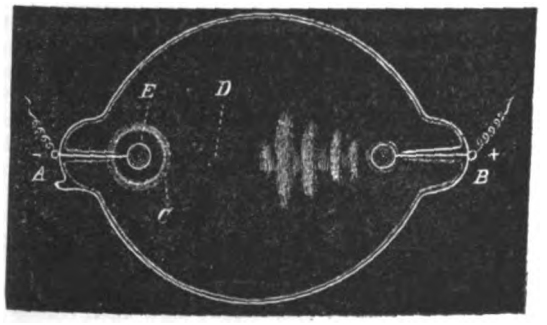

FIG. 3.—P = 3 MM.

If we pass to yet more minute substances we observe the behaviour of the molecules of a rarefied gas, when submitted to an induction current. The molecules here are free, of course, from any caprice, and simply follow the law I seek to illustrate, and though originally in a state of rampant disorder, yet under the influence of the electric rhythm they arrange themselves into well-defined groups or stratifications; the luminosities show where arrested motion with concomitant friction occurs, and the dark intervals indicate where the molecules travel with comparatively few collisions.

The Dark Space.—After the stratification stage is passed we come to a very curious phenomenon, the so-called "dark space." Separating the negative glow from its electrode is the dark space. In this tube it is so small that the glow appears to be in actual contact with the electrode, but on exhausting a little further it rapidly separates; and in the next tube (Fig. 3), containing air at a pressure of 3 mm., this dark space E has extended so as to remove the negative glow about 4 mm. from the electrode A. It is with this dark space that I particularly wish to deal to-night. Therefore I shall refer to it as the "dark space," meaning always that in the negative glow.

With hydrogen stratifications the contents of the tube under the electric discharge still obey the laws following from the average properties of an immense number of molecules moving in every direction with velocities of all conceivable magnitudes. But if I continue exhausting, the dark space E round the negative pole A becomes visible, grows larger and larger, and at last fills up the entire tube. The molecules at this stage are in a condition different from those in a less highly exhausted tube. At low exhaustions they behave as gas in the ordinary sense of the term, but at these high exhaustions, under electric stress, they have become exalted to an *ultra gaseous* state, in which very decided properties, hitherto masked, come into play.

The radius of the dark space varies with the degree of exhaustion, with the kind of gas in which it has been produced, with the temperature of the negative pole, and to a less extent with the intensity of the spark.

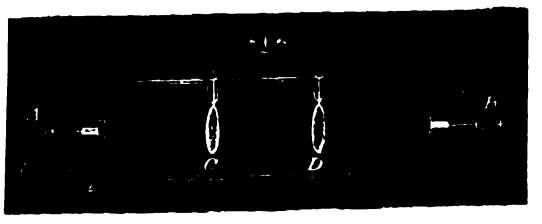

FIG. 4.

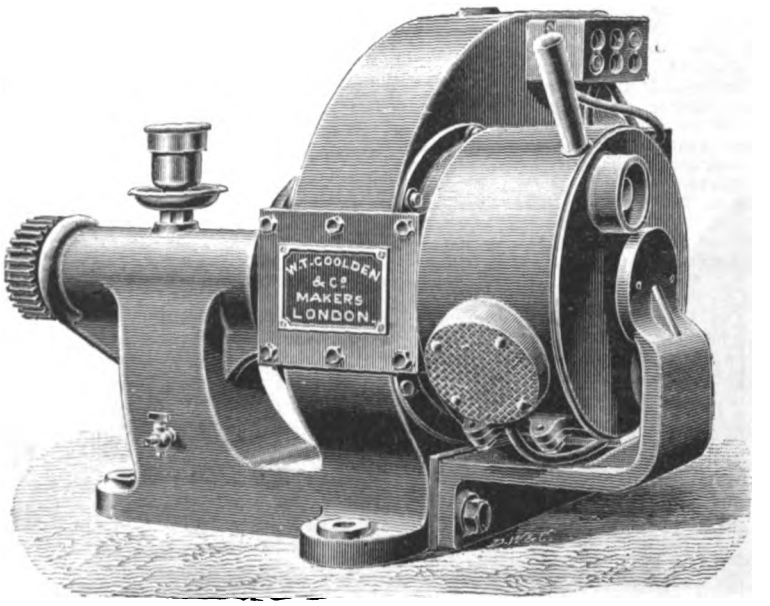
Exploration with Idle Poles.—Wishing to learn something of the electrical condition of the matter within and without the dark space, I made a tube (Fig. 4), having besides the positive and negative terminals A B two extra intermediate poles C and D. The tube showed that when the exhaustion was such that both the idle poles were outside the dark space, on passing the current through the tube, there was a considerable difference of potential between them when measured on the galvanometer. If the exhaustion was carried so high that one of the extra poles was just on the border of the dark space, then no current passed between them. When the exhaustion was still further increased so as to enclose one of the extra poles fully in the dark space, again there was a great difference of potential between them, but the direction was reversed, the pole at highest potential now being the one formerly at lowest potential.

When the dark space has been further explored by means of a movable negative pole, I found that the effects did not depend essentially on the exhaustion, and were really due to the position occupied by the extra poles with regard to the dark space.



When a substance that will phosphoresce under electrical excitement is introduced into the tube, the position of greatest luminosity is found to be at the border of the dark space, just where the two opposing armies of negative and positive atoms meet in battle array and recombine.

(To be continued.)

THE "GOOLDEN" MINING MOTOR.

CONSTRUCTED BY MESSRS. W. T. GOOLDEN & CO., ELECTRICAL ENGINEERS,

WOODFIELD WORKS, HARROW ROAD, LONDON, W.

THE "GOOLDEN" MINING MOTOR.

ONE of the principal difficulties with electric mining motors arises out of the rough conditions and dirty situations in which the motors have to be used, and a further difficulty in coal mines is the danger that occasionally arises from the presence of explosive gases. For ordinary purposes, even in coal mines, it may be safely assumed that the motor will not be working normally in an explosive atmosphere, and it is therefore sufficient to enclose the whole armature and brushes in air-tight and dirt-tight coverings. Such coverings would be sufficient to exclude an explosive mixture for many hours, and before such mixture found its way into the neighbourhood of the armature or brushes, the condition of the atmosphere would be noted by the attendant, and the current cut off. The above engraving shows one form of the "Goolden" mining motor as made by Messrs. Goolden & Co., London, which embodies, besides the complete enclosing of the armature, various other important features. The construction of the armature is unusually strong, the wires being keyed in every position, and insulated from the core and from one another by means of mica. These methods enable the machines to be used for driving hauling machinery subject to great vibration and shocks by the use of gearing, thus doing away with belts, chains, and other forms of connection, all of which have been proved in practice to be unsuitable for working or not portable.

For cases where it is desired to make a machine absolutely safe in an explosive mixture, Messrs. Goolden's patents cover an arrangement in which the volume of gas enclosed in the cover of the brushes in contact with the commutator is as small or less than that enclosed in an ordinary safety lamp, and therefore, should ignition result, the volume of gas, compared with the length and cooling surface of the outlet, is such that no flame will appear externally. These motors are now being widely adapted for use in electric coal-cutting machinery, electric pumps, electric haulage, and rock-drilling plants, and on a future occasion we hope to illustrate and describe some of these applications to practical mining.

THE PHYSICAL SOCIETY.

AT a meeting of this Society, held on the 16th inst., Professor W. E. Ayrton, F.R.S., President, being in the chair, Professor C. M. Minchin read a paper on "Photo-Electricity." His experiments on the subject were commenced in 1877, in attempting to produce a photographic image of a distant object. The result sought for has not, hitherto, been obtained, but the experiments have led to the discovery of many interesting phenomena. Some of these were shown to the meeting. Electric cur-

THE PREPARATION OF BORAX.

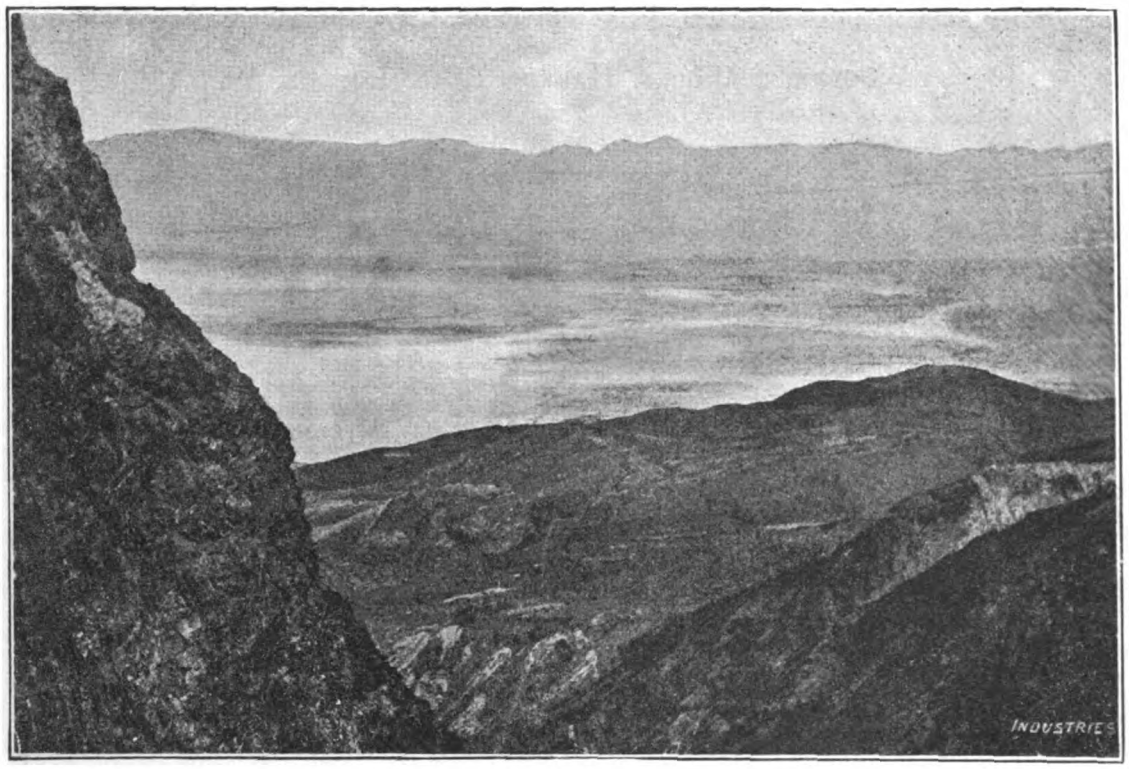

Fig. 1.—Saline Valley.

rents are produced by the action of light on silver plates coated with collodion or gelatine emulsions of bromide, chloride, iodide, and other silver salts, or with cosine, fluorescine, and other aniline dyes, when the plates are immersed in a suitable liquid and one plate illuminated whilst the other is screened. The directions of the currents depend on the materials employed, and the blue end of the spectrum is most effective. Currents have a photographic effect on the plates, and this action is strictly confined to the parts through which the current has passed. Comparatively strong currents were obtained from plates coated with cosine and gelatine. A curious reversal was observed with some cells, the exposed plate first being positive to the screened one, and almost immediately afterwards negative. On shutting off the light a transient increase of current resulted, and afterwards disappeared gradually. M. Becquerel, who has studied the action of silver plates coated with bromine, &c., concludes that the nature of the exposed plate (whether positive or negative) depends on the thickness of the surface layer. The electromotive force of such cells rarely exceeds $\frac{1}{20}$th of a volt.

Uncleaned tinfoil plates in common tap water give a current when one is exposed to light and the other screened. Cleaning the plates destroys the effect. In nearly every case the exposed plate was first positive, and, after a time, became negative; and by exposing various parts of a plate (some portions of which had been previously exposed) the currents could be varied in direction at will. These peculiarities may explain the known divergence of tin from Volta's law. The phenomena have also been studied by aid of the electrometer. Tinfoil obtained from tobacco packages was found to be very sensitive to light. One side of such foil is dull and the other bright. By pasting slips of it on opposite sides of a glass plate, so that dissimilar sides were outermost, and immersing them in alcohol, a cell giving an e.m.f. of $\frac{1}{10}$ volt when the dull side was exposed to light was obtained. The addition of any salt to the liquid, with a view to diminishing the resistance, invariably reduced the e.m.f. Experiment showed that the alcohols were by far the best liquids to use with tinplates. A process for producing very sensitive tinplates was described, which apparently results in the formation of white oxide of tin on the surface of the foil. With one such plate and another unsensitised plate the best results have been obtained by immersing them in methyl alcohol prepared from oil of wintergreen. From experiments on the variation of e.m.f. with the intensity of light, it was found that the square of the e.m.f. is proportional to the intensity.

Some tin cells behave in a very peculiar manner, for it often happens that a good cell will exhibit no e.m.f. after being kept a few days. A slight impulse or tap given to the cell or its support restores the sensitiveness; another impulse makes the cell unsensitive, and these effects can be repeated indefinitely. Such cells the author calls "impulsion cells," and some were exhibited at the meeting. The sensitised plate of one of these cells had different properties at its two ends, for impulses had no effect on the nature of the lower end, but changed the upper end from positive to negative, and *vice versâ*. Electromagnetic impulses, such as are produced by sparks, are capable of altering cells from the unsensitive to the sensitive state, but fail to produce the reverse effect; a Hertz oscillator restored the sensitive state in a cell placed at a distance of 81ft. away. The "impulsion effects" can be got rid of by renewing the alcohol on several successive days.

During last year the author made some selenium cells by spreading the melted substance on metal plates and immersing them in liquids together with an uncoated plate. Of the various metals and liquids tried, aluminium and acetone gave the best effects. The process of forming these "seleno-aluminium cells" was described. One of their peculiarities is that they are nearly equally sensitive to rays of all colours, and when exposed to strong light may give an e.m.f. of $\frac{1}{2}$ to $\frac{3}{4}$ of a volt, the sensitised plate being negative. An arrangement of 50 cells in series with an electrometer was exhibited, whereby the e.m.f. generated by light falling on the cells could be caused to ring a bell and light or extinguish electric lamps.

In conclusion the author pointed out the possible applications of photo-electricity to photometry, telephotography, and the utilisation of solar energy. At the request of the President, Professor Minchin promised to show the experiments on February 13th, on which date the discussion on the paper is to take place.

Professor F. R. Barrell then exhibited and described a lecture-room apparatus for determining the acceleration due to gravity. A number of iron balls are allowed to fall through a certain height in such a way that one starts off when its predecessor arrives at its destination. From the time occupied by all the balls, the time for one can be found, and, knowing the distance traversed, "g" can be determined. The apparatus consists of two electromagnets joined in series with a battery and key, together with a ball-feeding device. One of the magnets is vertically over the key, and serves to catch the balls as they emerge from the feeding tube, whilst the other magnet actuates a kind of slide for supplying successive balls. When one ball falls on the key it breaks circuit, and thus causes the first-mentioned magnet to let go its ball. The key then springs up again, thus making circuit; the feeding magnet then supplies another ball, which is caught by the holding magnet until the falling ball reaches the key, and the operations are repeated. Fairly accurate results can be obtained by the apparatus.

Sir John Conroy's paper, on "The Change in the Absorption Spectrum of Cobalt Glass by Heat," was postponed.

THE PREPARATION AND INDUSTRIAL APPLICATION OF BORAX.

Although very little information on the subject of borax, is afforded in books of chemical technology, chemistry, and other scientific works, it is nevertheless an article used more or less extensively in a number of industries.

When the supply was limited to the "tincal" obtained from deposits found in the Himalayan Mountains of Southern Thibet and Northern India, and brought from thence upon the backs of sheep to the highways of commerce, the demand was confined simply to the working of precious metals. Then came the utilisation of the boracic acid, found in the vapours of the suffioni, at Monte Rotondo and the surrounding neighbourhood, in Tuscany, by Count Lardarel.

But notwithstanding the most strenuous efforts to increase this supply, not more than 3,000 tons could be obtained per annum, and this, by a simple process, was converted into borax. The demand by china and earthenware manufacturers for borax as an ingredient for their glazes soon caused this source to be entirely inadequate to the demand. In the year 1869 the borate of lime mines, of Suzurlu, in Asia Minor, were opened, and from this source from 7,000 to 8,000 tons of borax are annually obtained. Prior to that, in the year 1856, borax was discovered in California by Dr. John A. Veatch, since which time no less than ten deposits have been discovered and operated in North America. Five of these are situated in California, and five in the neighbouring State of Nevada. The Californian marshes are situated at Saline Valley, Furnace Creek, and Armagosa, all in the county of Inyo; Slate range in San Bernardino County, and Lower lake in Lake County. The Nevada marshes are at Rhodes, Teels Marsh, Fish Lake, and Columbus, in the county of Esmeralda, and Salt Wells, in Churchill County. By far the richest marsh is Saline Valley The crude borax there covers the plain, which is 18 miles long by 12 miles wide, for an area of over 1,000 acres, with a depth of from 6in. to 18in.

The borax is mixed with sand, sulphate of soda, carbonate of soda, and salt. The colour of the crude material as it lays upon the plain is of a peculiar greyish yellow, giving the surface the appearance of snow somewhat tinged by age. The material varies in richness from 10 to 90 per cent. of pure borax.

Surrounding the plain are a complete circle of mountainous hills, with here and there a copse of mesquit, manzanita, or shellac wood, and, looking over the dry and arid marsh towards the mountains, small streams of pure fresh water may be observed, affording not only a pleasant relief to the eye, but a great boon to those employed in the industry. Saline Valley is on the eastern slope of the Sierra Nevada Mountains, 11 miles from the line of the Carson and Colorado Railroad Company, and its topographical aspect is best described by comparing it to an immense saucer.

As regards the various uses of borax, manufacturers of china, earthenware, white glazed bricks and tiles use borax in making "fret" for glazing the different descriptions of goods. Cement, likewise, compounded with borax, possesses the quality when set with water of taking a polish like marble. In the hardware trade it is used for enamelling copper and iron. In this capacity borax reduced to a glass forms a vitreous coating. Gold and silversmiths use it in soldering and reducing the precious metals; coppersmiths apply it to brazing, and ironsmiths to welding. In connection with the textile trade, silk weavers employ a solution for dissolving the glutinous matter adhering to raw silk; hat makers as a solvent for shellac to form a stiffening; dyers and calico printers as a mordant; laundrymen, in conjunction with starch, for putting a beautiful gloss or finish upon linen after being ironed; and paper makers, in the fabrication of highly glazed paper. Colour manufacturers use it in the preparation of Guignet's green and borate of manganese, which acts as a drier. Photographers use it in print varnishing, and the formation of toning baths for silver prints. As a fireproof material it is used as a lining between the inner and outer shells of safes. The candlewick maker, on the other hand, uses it for steeping the wick, so that when the candle is lighted the wick curves over and is completely burnt away. The property borax possesses of softening hard water renders it useful to the soap manufacturer.

The success which has attended the introduction of borax as a food preservative may be judged from the fact that, in 1883, 2,000lb. weight was used for the purpose of preserving hams and bacon by the pork packers of Chicago, Kansas City, and St. Louis, whilst in 1888, or five years afterwards, over 2,000,000lb. weight was used for the same purpose. The great advantage of borax as an antiseptic lies in its purity and agreeable properties. It is odourless, easily soluble in water, of a pleasant sweetish taste, and resembles in appearance

Digitized by Google

the finest sugar or refined table salt. It is harmless, in fact, it is considered to benefit the human system, as its employment in over a dozen pharmaceutical preparations would denote. It enters into the composition of the following medical preparations:—Boroglyceride, borax lozenges, ung-acidi-borici, borax lint, glycerinum boracis, borax pastilles, boro-tartrate of potash, mel boracis, glacialin, and tartarus boraxatus.

Our illustrations, which are from photographs, represent in Fig. 1 the borax marsh at Saline Valley, where the crude borax is seen lying on the plain, and in Figs. 2 and 3 views of the reduction works and dwellings. The method employed of refining the crude borax consists in, first of all, collecting the material from the plain. This is done by simply shovelling layers of the surface to a depth of 18in., and loading it into waggons provided with wide tyres to the wheels to prevent them sinking into the loose friable mass. Below the surface of the marsh at a depth of 4ft. liquor is found highly impregnated with borax. The material is hauled to the refining works, which are conveniently situated upon firm ground at the edge of the marsh.

The next process consists in dissolving all the soluble matter in the crude material. For this purpose wrought-iron pans are used, about 35ft. long by 7ft. wide, semi-circular in shape, set on arches of stone, beneath which are furnaces and flues for heating the contents of the pans. They are supplied with water from the neighbouring mountain streams by means of iron pipes, and the fuel necessary for boiling the water is obtained from the timber growing in the immediate vicinity, of which there is an immense quantity. The crude borax is thrown into the pans, and with the aid of long poles is vigorously stirred until all that is soluble is dissolved; the liquor is then allowed to settle for some hours, and when perfectly clear is drawn off into round tanks made of light galvanised iron, where the borax crystallises on cooling. When the crystallisation is complete, the "mother liquor" is drawn off, leaving only the crystalline borax, which is removed and packed into sacks for commerce.

The operation is conducted inexpensively as far as the production of the borax is concerned, the principal item of expense in connection with its cost for commercial purposes being the railway carriage from the point of consignment to New York, which amounts to £7 10s. 8d. per ton. All the other outlay is said not to exceed £5 per ton. As the price of borax in Great Britain is about £28 per ton, it will be seen there is considerable profit attached to its manufacture, which is due to the fact that all the borax deposits throughout the world are in a few hands and consumers are largely under the control of the producers.

THE ANALYSIS OF THE AIR OF LARGE CITIES.

The question of air pollution is being taken up in earnest in Manchester. Certainly the smoky condition of the atmosphere of our large cities has, in conjunction with fogs, been brought prominently forward during the long frost, and any movement which has for its object the minimising of the evil has our hearty support. The late Dr. Angus Smith, in his book on "Air and Rain," gave a *résumé* of the large amount of work he had done in connection with air analysis, but not much attention seems to have been given to the subject in recent years. Much remains to be cleared up as to the origin of fogs, although a good deal of attention has been paid to the matter by Aitken, whose papers have appeared in the *Philosophical Magazine*. It was thought, therefore, that a systematic series of analyses, carried out at different points of a large city at the same time, would give valuable information as to the chief causes of pollution, and to this end a chemical sub-committee has been appointed by the Town Gardening Section of the Manchester Field Naturalists' Society. The committee consists of Dr. Bailey, Dr. Cohen, and Mr. P. J. Hartog, B.Sc., of the Owens College Chemical Staff, and Dr. Tatham, Medical Officer of Health for Manchester. A subscription list was opened to defray the cost of apparatus, &c., and about £200, the sum required, has been raised.

The analytical scheme is a very comprehensive one. The observations, which are to be made at seven different stations in Manchester and Salford, are intended to afford definite information on the following points:—

1. The composition of the air in densely populated as compared with thinly populated districts.
2. The relation between atmospheric impurities and prevalent sickness and mortality.
3. Amount and distribution of noxious ingredients specially injurious to plant life—*e.g.*, sulphurous acid.
4. The extent to which smoke and noxious gases are due to (*a*) dwellings; (*b*) factories.
5. Nature of fog, and the chemical character of the air during the prevalence of fogs.

At a meeting of the Society on the 7th inst. Dr. Bailey reported that their investigations had been commenced. They had found, he said, that the snow carried to the ground large quantities of sulphuric and hydrochloric acids, and also some of the elements of sewage. The depositions on leaves collected at the various observing stations were in amount directly as the population, and the greatest injury to plant life was found to be due to the emanations from dwelling-houses. They estimated that, in one day, two tons of "blacks" and 3 cwt. of sulphuric acid were deposited per square mile of the city area. The above figures are sufficient to show that much interesting and valuable information may be looked for when the final report of the committee is issued. On similar lines, a committee, with which the names of Professor Oliver and Mr. Scott, the botanists, are associated, has been appointed in London, the initiative being due to the Royal Horticultural Society.

THE PREPARATION OF BORAX.

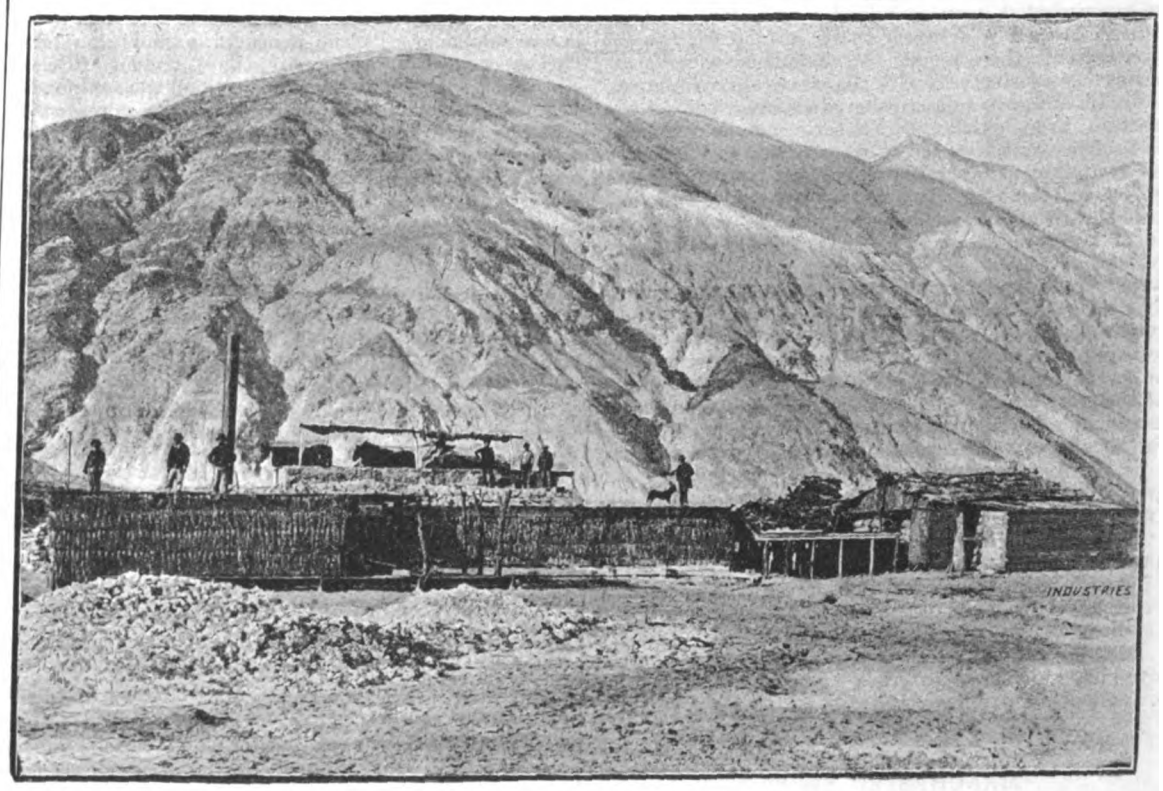

Fig. 2.—Reduction Works.

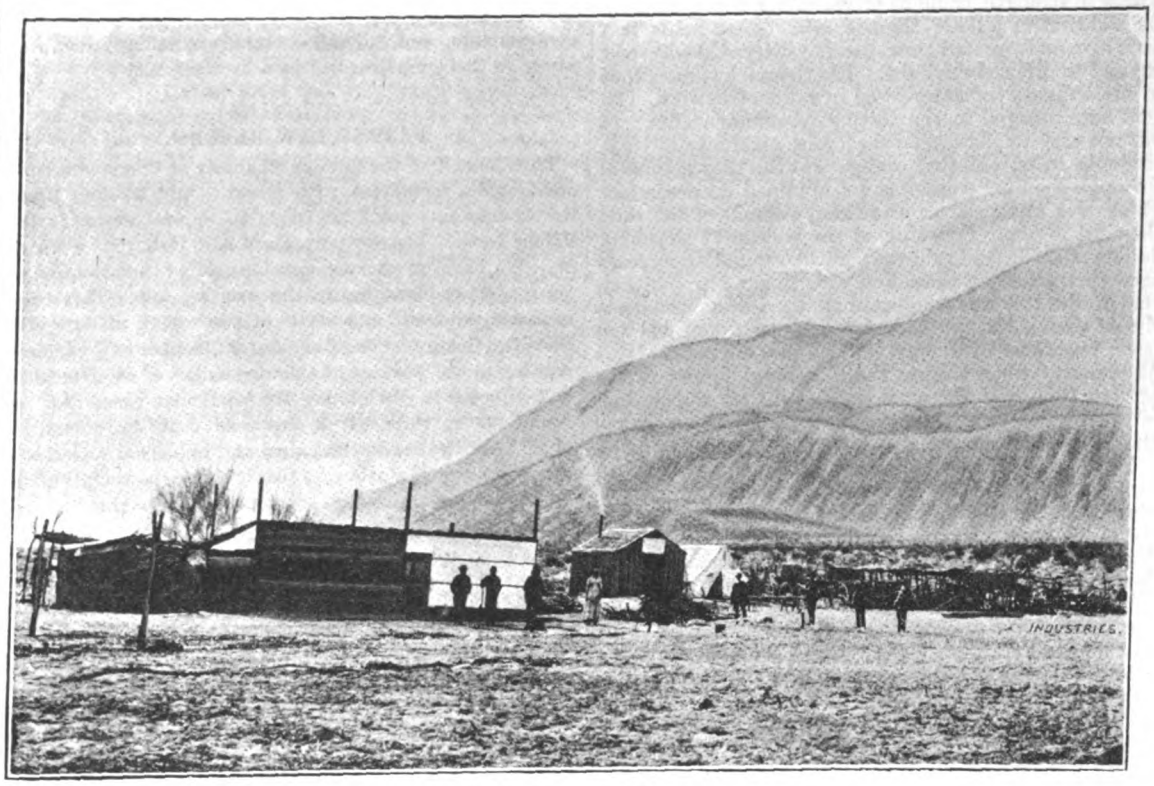

Fig. 3.—Dwellings of Workpeople.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

An extra meeting of this Society was held on the 19th inst., when a paper was communicated by Mr. J. A. Wanklyn, on "The Constitution of Butter." The evidence which the author put forward in favour of the novel views which he held on this subject was severely criticised by Dr. C. R. A. Wright and Messrs. O. Helmer and Allen, of Sheffield.

Subsequently a paper was read by Mr. Watson Smith, on the McArthur Forrest "Cyanide Process for the Treatment of Gold Ores," in which the author gave a short account of laboratory experiments made with a view of ascertaining the efficacy of the process with poor grade ores. Our readers will be aware that this process consists in agitating the crushed ore with a

Digitized by Google

solution of potassium cyanide, and then passing the solution of gold cyanide so obtained over zinc turnings, and finally recovering the gold from its zinc alloy by distillation. Three experiments were given in detail by the author, showing the variation of yield with strength of cyanide solution and length of agitating time. The ore experimented upon contained both gold and silver, and the process was shown to be suitable for the recovery of both these metals, the amount recovered comparing very satisfactorily with the assay values of the ore.

Mr. Blount gave a description of his experience of the process. From his laboratory experiments, he concluded that a 1 per cent. solution of cyanide was as efficient as one containing 2·5 per cent., and that the process was applicable to certain Australian ores which had not yielded satisfactory results when treated with chlorine under pressure. Several speakers followed, who gave evidence of the satisfactory working of the process on a large scale in South Africa, and Mr. Vautin pointed out that in gold-bearing rocks in which there was much pyrites, the cyanide process was far more economical in working than any of the chlorine processes with which he was acquainted. He threw some doubt on the validity of the patent, and stated that he believed anyone could use cyanide for the recovery of gold from these ores. He further suggested the use of an alloy of 99 parts zinc and 1 part sodium as a better material for precipitating the gold from the cyanide solution than the zinc foil and turnings at present employed.

Dr. Rideal regretted that those interested in the rival processes had not joined together to carry out a series of experiments on the same kinds of ore in order that the relative values of the different gold extracting processes might be placed on some scientific basis.

Mr. Watson Smith showed specimens of the crude cyanide, zinc, and materials at present used by the owners of the patent.

MANCHESTER SECTION.

At a meeting, held on the 9th inst., Mr. Hart being in the chair, Dr. Gerland contributed some laboratory notes. He had found that standard oxalic acid, which was liable to alter in strength, could be preserved for a long time by the addition of a little thymol acid. Some made two years ago, and, treated thus, had not altered at all when exposed to diffused daylight. The thymol had no action on the ordinary indicators used in volumetric work. The next note referred to the testing of alumina salts. It was not easy to determine the exact alkalinity of basic luminous salts. Methyl orange was the best indicator, although the final point was not obtained at once, a fact which was instanced as a striking example of retarded chemical action. Speaking of the testing of bleaching liquors, Dr. Gerland said that he had found some years ago, when titrating these liquors with arsenite solution, that if the test was conducted slowly less chlorine was shown than if the test occupied a longer time. He had never been able to account for this, and did not find this discrepancy when testing the bleaching liquors of the present time, and therefore suggested that the product of the Weldon process differed in some way from that of the old Deacon process.

In the ensuing discussion, Dr. Grossman said that the strength of bleaching liquors always deteriorated on standing. By testing in different ways, different results were obtained. If the bleaching powder was sent out from the works warm it frequently happened that the free oxygen present caused the conversion of hypochlorite into chlorate, and this not only meant a loss of chlorine, but he had also known it to lead to explosions. If Dr. Gerland had not made his tests in alkaline solution, of course chlorine would be generated by the decomposition of chlorates.

Dr. Gerland said that he had tested in alkaline solution.

Mr. Carter Bell said that he saw no advantage in using standard oxalic acid; he used standard hydrochloric in all cases, and always weighed it out instead of measuring it for accurate work.

Mr. J. A. Wilson then read a paper on "Turkey Red Oil." This oil, he said, owed its name to the fact of its being used in turkey-red dyeing. It was first introduced in 1876, and results from the interaction of sulphuric acid on olive or castor oil. The manufacture consists—first, of the hydrolysis of the fatty oil, and, secondly, of the purification of the product and partial neutralisation with alkalies. The acid used, which varies from 15 to as much as 40 per cent. of the weight of oil, is added gradually, so as not to cause a great rise of temperature. The purification is effected by washing with brine and dilute alkali, the resulting product having approximately the following composition—1·3 per cent. Na_2O, 20 per cent. free fatty acid, and 25 per cent. glycerides—and is usually sold on the basis of 45 per cent. fatty matters.

Mr. Wilson proceeded to deal with the applications of the oil in dyeing and calico printing, and then gave a *résumé* of the theories held as to its constitution. The study of this involved a knowledge of the reaction of sulphuric on both oleic acid (olive oil) and ricinoleic acid (castor oil), and here chemists differed. The fatty matters are partly soluble and partly insoluble in water. The soluble part is believed by Liechti and Suida to consist of glycerol sulphates, while Müller Jacobs considers them as free sulphonic acids, and Benedikt as sulphuric esters. This experiment did not confirm the statement of Benedikt that by boiling castor turkey red oil with sulphuric acid ricinoleic acid was produced. It was noteworthy that the more castor and olive oil were acted on by sulphuric acid the less iodine was absorbed in Hübl's test. In conclusion, the following analytical scheme was given as being the most satisfactory to use. The specific gravity is taken by a Westphal balance, and varies from 1·135 to 1·017. The total alkali is determined by H_2SO_4. The free fatty acids are dissolved out with alcohol and ether at a low temperature and titrated with alcoholic potash. The total fatty matter is determined by shaking up the oil in a separator with brine and strong HCl, and subsequently extracting with ether.

An animated discussion on the chemical constitution of the oil followed the reading of the paper.

Notes.

SMALL ELECTROMOTORS.

It is often said that there should be an enormous demand for small direct or alternate current motors for driving hoists, printing machinery, small workshops, sewing machines, amateurs' lathes, knife-cleaning machines, hairdressers' brushes, and so on. Before central stations were established the good time for motors seemed to be in the far future. Now, however, we have central stations, yet not a motor is to be seen. When gas engines were new, grocers liked to have nickel-plated specimens on show in their windows driving coffee-grinding machines, and the enterprising printer advertised that he printed by gas power. Why do not similarly enterprising people use electromotors, and advertise that everything requiring power on their premises is driven by electricity?

PATENT LAW REFORM.

The Council of the London Chamber of Commerce have nominated a committee, with power to add to their number, to take any steps advisable to secure reform in the Patent Laws. The committee will find plenty of work to do. We have on various occasions called the attention of our readers to blemishes in the existing law. This committee is, no doubt, one result of the report made by the Chemical Section of the Manchester Chamber of Commerce, relating to the practice of claiming a class of combinations, and afterwards disclaiming the particular cases that are found not to work. It is proposed that the committee should ask the various technical and industrial societies to nominate representatives, so that it may be powerful enough to hope to see their suggestions carried through.

THE NEWSPAPERS OF THE WORLD.

The printing industry is not only important in itself, but also because of its immense general influence. The department in which this influence is greatest is that of newspapers, the number of which published in all countries is estimated at 41,000. Of these 24,000 appear in Europe. Germany heads the list with 5,500; then comes France with 4,100, Britain with 4,000, Austria-Hungary with 3,500, Italy with 1,400, Spain with 850, Russia with 800, Switzerland with 450, Belgium and Holland with 300 each, and the remainder in the smaller countries. The United States have 12,500 newspapers, Canada has 700, and Australia also 700. Out of the 300 journals published in Asia, Japan alone has 200. If this is any measure of progress, the latter country has progressed immensely, for twenty years ago it had no newspapers.

EDIBLE EARTH.

The villagers of Penacova, in Portugal, have for generations eaten a variety of earth obtained in the neighbourhood. All ages and both sexes chew it as if it were tobacco. Unfortunately any one of them leaving home is afflicted with "a singular *maladie du pays*, with gastric symptoms," unless he be provided with a supply of the earth. It is a tale like that told by Bret Harte of "The Wonderful Spring of San Joaquin" over again, and the reason is very probably the same—namely, the presence of arsenic in the earth, which is known to produce these singular effects upon its habitual consumers. The fact that Dr. Vogel has found none in it by a cursory examination, but, on the contrary, has detected that it contains about double the quantity of nitrogen found in similar soil from the adjacent fields, lends plausibility to the view that the active substance may be an alkaloid. The whole question could be easily settled by a competent chemist, and it is to be hoped that someone will undertake its investigation.

THE PANAMA CANAL.

The Paris *Figaro* published, on Monday last, the text of the arrangement concluded between the Government of the United States of Columbia and the Panama Canal Company, according to which the following are the principal clauses of the contract:—"(1) The time allowed for the completion of the canal is extended for a further period of ten years; (2) the concessionnaire to effect the liquidation of the old company, the assets of which will be transferred to the new company; (3) work on the canal to be effectively resumed before February 28th, 1893; (4) the concessionnaire to provide for the support of 250 soldiers charged to protect the line of the canal during its construction; (5) the concessionnaire, in exchange for services rendered by the Columbian Government, will pay to the latter ten million francs in gold and five million francs in 10,000 of the new company's shares; (6) the Columbian Government will have the right of appointing a special delegate to sit on the board of the new company." The contract bears date December 10th, 1890, and is signed by Señor A. Boldan, Minister of Foreign Affairs, on behalf of the Columbian Government, and by Colonel Bonaparte Wyse, the representative of the liquidators of the old company.

THE SUDBURY NICKEL MINES.

A report on the Sudbury Nickel Mines, of which an account recently appeared in our columns (see *Industries*, Vol. IX., p. 530), has been drawn up by commissioners who were appointed by the United States naval authorities for that purpose. The report states that from the surface indications and the shafts already sunk, there appears to be an amount of mineral which cannot be exhausted by the present generation, and estimates the tons of ore above the surface of the ground as 650,000,000. With reference to facilities for treating the ores, which do not require the admixture of fluxing substances, it is stated that "the dead pine timber found in great abundance in the neighbourhood, and which can be delivered at the furnace at $1 80c. a cord, is a good fuel for roasting though hardwood would be better, but owing to the fusible qualities of the ores and the intermixed rock, it answers the purpose. Coke is hence the only material that has to be brought from abroad. This is procured from Pittsburgh, and can be delivered at the works at $7 a ton." The amount of ore taken from the mines up to the 1st October last is about 175,000 tons. The daily crushing capacity of the machinery at work on the ground is about 1,750 tons, and the daily furnace capacity is about 100 tons.

THE COTTON INDUSTRY.

The prolonged absence of demand in cotton goods from India is telling somewhat seriously upon the weaving industry in Blackburn and East Lancashire. Many of the shirting makers in low and low medium qualities are wanting orders, and here and there machinery (looms) is being allowed to stand idle. Moreover, the outlook from our dependency in regard to a cloth demand is not very encouraging. For China slightly more inquiry has this week been about in heavy goods, such as best sheetings and best drills. Altogether, however, the weaving section of our trade is discouraging, and those who buy yarns to make into cloth are having a lean trade. Those who spin as well as weave are rather more fortunately situated. Spinners, during the past three weeks, have lost ground both in point of demand and margin. In the lower qualities of cop-twist (34's) the margin is said to be ⅛d. per lb. worse than a month ago. Several things are going against spinners—viz., lessened consumption of yarn through bad weaving weather, hardening of cotton, and increased wages. Moreover, there are several new mills getting to work, and thus increasing the supply of yarn upon the market. Viewing both spinning and manufacturing, the position may be said to have gone worse since Christmas.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

5th January, 1891.

171. Gillespie, A. ..... Pumps.
174. Titley, J. ..... Pistons for gas and other engines.
179. Davy, A. S. ..... Apparatus for treating smoke and gases from furnaces.
183. Hookham, G. ..... Paper tube making machines.
190-1. Gray, A. ..... Gas and hydrocarbon engines.
198. Euler, H. ..... Alarm for indicating the level of water in boilers.
199. Jerger, H. ..... Water engine.
205. Cochrane, C. ..... Blast furnaces.
207. Jules Lussiez & Cie. ..... Apparatus for winding and dyeing wool.
213-14-15. Edwards, D. ..... Apparatus for making tin and other coated metal plates.
216. Edwards, D. ..... Rotary steam engines (*Gwinner & Schraivogel*).

6th January, 1891.

225. Tower, C. A. ..... Steam engine.
227. Bickerton, H. N. ..... Gas engines.
234. Hanson, F. ..... Screwing machines.
241. Edge, C. ..... Engine governor gear.
245. Ethbert, H. ..... Balls for ball-cocks, ball-valves, &c.
246. Scott, W. ..... Printing presses.
248. Corning, F. G. ..... Mechanism for transferring electric car batteries. (9th June, 1890.)
267. Dolby, E., Jun. ..... Relief valve and drain and indicating cock for steam engines.
276. Thompson, W. P. ..... Rotary engines (*Chapleau*).
286. Chapman, Petrie, Petrie, Gilbert, & Jones ... Nut-tapping machines.

7th January, 1891.

287. Hahlo, Liebreich, & Hanson ..... Drop box looms.
289. Townson, T. ..... Steam engine pistons.
297. Bickerton, H. N. ..... Gas engine governors.
304. Sharp, T. ..... Method of and means for rolling metallic bars and plates having taper longitudinal sections.
305. Sargeant, T. C. ..... Engine governors.
310. Jones & Jones ..... Grinding mills.
316. Coleman & Ackland ..... Machinery for making paper bags.
333. Sampson, J. ..... Valves and their seats.

8th January, 1891.

342. Hollingworth, E. ..... Machines for milling bolts (*Webb*).
343. Hollingworth, E. ..... Bolt-heading machines (*Webb*).
348. Ashworth, Ashworth, & Ashworth ..... Card-setting machines.
354. Dent, H. ..... Grinding mills for pulverising clay, &c.
355. Dent, H. ..... Brick-making machinery.
360. Parkes & Wheeler ..... Grinding and polishing machinery.
362. Hill, W. T. ..... Machines for making horseshoes.
364. Whitaker, G. ..... Pistons of steam and like engines.
380. Silvester, J. ..... Signalling apparatus.
383. Boult, A. J. ..... Valve reversing gear of gas, petroleum, and other engines (*Berliner Maschinenbau-Aktiengesellschaft*).

9th January, 1891.

396. Cohnen, B. ..... Stop motions for looms.
414. Burrell, F. J. ..... Compound portable and traction engines and road rollers.
431. Perkins, W. J. ..... Wood-working machines.
441. Doloire & Golay ..... Mill for grinding cereals. (30th June, 1890.)
447. Smith & Binney ..... Machinery for polishing plate glass.
455. James, R. ..... Device for holding tools while grinding.
459. Hardingham, G. G. M. ... Steam boilers (*Morrin*).
460. Webster, J. M. ..... Box-nailing machines.

10th January, 1891.

465. Musgrave, W. ..... Steam boilers.
469. Hughes & Catchpool ... Attachment for lathe, drilling machine, or brace, for drilling square and polygon holes.
472. Veska, A. ..... Stamping mills for disintegrating ore.
477. Hughes & Evans ..... Lateral movement chucks.
505. Munns, W. H. ..... Railway switch (*Copeland*).
507. Munns, W. H. ..... Car coupling (*Bowling, Follett, & Follett*).
518. Jones, A. P. ..... Steam boilers (*The Société Anonyme du Générateur du Temple*).
523. Phillips & Hughes ..... Drilling machine for forming square, polygonal, or mortise holes.

ELECTRICITY.

5th January, 1891.

176. Garnett, W. T. ..... Dynamos and motors.
184. Crompton, R. E. B. ..... Armatures of dynamos.
185. Crompton, R. E. B. ..... Dynamos.
200. Brianne, L. ..... Arc lamps.

6th January, 1891.

223. Todd, W. H. ..... Primary batteries.
258. Gay & Hammond ..... Arc lamps.
271. Schoennerstedt, A. ..... Arc lamps.
284. Mayer, E. L. ..... Telephone transmitter.
285. Mayer, E. L. ..... Method of telephonic transmission and apparatus therefor.

7th January, 1891.

303. Harding, C. K. ..... Electric railway systems. (9th June, 1890.)

8th January, 1891.

361. Webb & Thompson ..... Dynamos.
389. Teague, F. ..... Electricity meters.
394. Goolden & Evershed ... Electricity meters.

9th January, 1891.

439. Mills, B. J. B. ..... Torpedoes propelled and steered by electricity (*Sims*).

10th January, 1891.

476. Banta, W. E. ..... Coupling for electrical conductors. (11th June, 1890.)
508. Munns, W. H. ..... Underground electric conduit (*Young*).
536. Atkinson & Atkinson ... Dynamos and motors.

CHEMISTRY.

6th January, 1891.

266. Anderson & Brand ..... Manufacture of alkalies and chlorine.

7th January, 1891.

340. Claus, C. F. ..... Manufacture and carburetting of hydrogen.

9th January, 1891.

440. Haddan, H. J. ..... Anti-corrosive composition for boilers.

10th January, 1891.

517. Bonne, C. R. ..... Method of combining acetic radicles with aromatic amine (*Köhler*).

MISCELLANEOUS.

5th January, 1891.

180. Langley-Smith, W. T. ... Propelling ships.
210. Langer, T. ..... Fusible mass for case-hardening.

6th January, 1891.

229. Talbot, H. ..... Manufacture of steel and iron wire.
247. Hughes, F. ..... Metallic packing for stuffing-boxes, pistons, and the like (*Pickhardt*).
275. Pike, H. ..... Metallic alloys.
283. Mayer, E. L. ..... Extraction and recovery of gold.

7th January, 1891.

298. Ryves, E. J. ..... Manufacture of explosives and apparatus therefor.
300. Hirst & Hirst ..... Method of and apparatus for hardening and tempering wire.
324. Dahlgren & Svensson ... Turning of angular sections on lathes.

10th January, 1891.

516. Watt, A. ..... Treatment of copper ores.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

15865. Jackson. 19310. James Watts, Edmund Benson Styring, & Herbert George Froud.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Faller Drilling Machine.—*W. Fortune & F. H. Bentham, both of Bradford.*—In the annexed illustrations Fig. 1 is a side elevation, Fig. 2 a plan, and Figs. 3, 4, 5, 6, and 7 details of the gantry and other parts of an ordinary faller drilling machine, embracing the improvements of this invention. The drill spindle A is traversed longitudinally in the ordinary manner by means of slide B and lever C, mounted on stud D, to which is connected the strap E passing over pulley F, and carrying a weight F^1, which regulates the feed pressure of the drill. The drill is withdrawn from the hole at each rotation of a cam G on shaft H, which latter is revolved from I. The cam G acts upon a loose pin K in the slide B, so traversing the latter to withdraw the drill at each revolution of the cam. The pin K may be raised and held out of contact with G when it is desired to use the machine for hand drilling. The fallers are mounted, as usual, in the holder L formed on saddle M sliding on slide N, and operated by the screw O carrying ratchet wheel P engaging pawl Q pivoted to disc R, which also carries a winch handle S. This handle, when the disc is free, revolves the latter until a

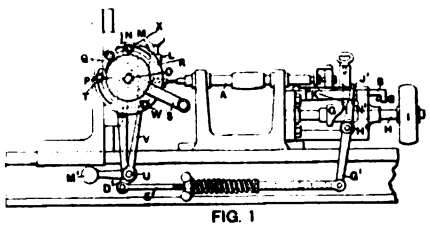

FIG. 1

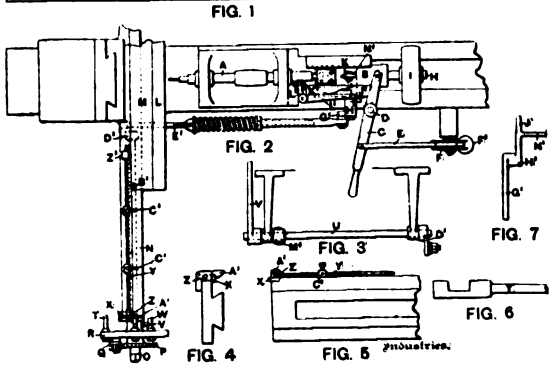

FIG. 2

FIG. 7

FIG. 3

FIG. 4

FIG. 5

FIG. 6

stud T, projecting from the back of the disc, comes against N, so slipping the pawl back upon the ratchet. The forward motion of O and traverse of M is communicated from the rocking shaft U (Fig. 3), provided with an arm V, which, when its shaft is rocked, strikes against the stud W and turns R, and with it P and Q, until X comes against N. To stop the traverse of M a rod Y (Fig. 6), mounted in bearings Z Z^1, and capable of a little longitudinal motion, is used. A hook A^1 is pivoted in a slit across Z, and is normally held up clear of X by its shank resting upon the extreme end of Y (Figs. 5 and 6). But by slightly moving Y the shank of A^1 drops into recess in Y, and the hook engages X so that the disc is held stationary. The movement of Y is effected by a stud B^1 fixed on the saddle, which strikes against the adjustable studs C^1 projecting horizontally from the rod Y. The shaft U is mounted in hangers (Fig. 4) fixed to the underside of N. The short arm D^1 fixed at the other end of U is connected by rod E^1 to arm G^1 of the catch lever H^1. The catch lever H^1 is normally held in the position shown by the spring catch I^1 engaging the top J^1 of such lever, but when the drill completes each hole in the faller and passes through, the parts are so relatively arranged that the end of the slide B reaches the adjusting screw K^1 in the arm L^1 of the catch, and turns the latter on its pivot. Then the lever H^1 is free to allow the weight M^1 to turn the shaft U and its connections, so that the arm V leaves W and allows the disc R to turn until its stud T touches the back of the slide N. The motion of H^1 is limited so that the back of the pin K does not reach the projection N^1 on the arm J^1 until the drill is completely clear of the faller, then it pushes the lever back until it again engages the catch and actuates the pawl and ratchet by the connecting mechanism so as to traverse the saddle and bring the faller into position for drilling the next hole. Four claims are made.—No. 20466. December 20th, 1889. 8*d.*

Boiler Furnaces.—*H. H. Lake, London.* (*R. L. Walker, Boston, Massachusetts, U.S.A.*)—The object of the present invention is to save fuel and prevent smoke. For this purpose the inventor forms the grate in two sections. The front portion of this grate is stationary, and the bars are placed parallel to the length of the furnace. The second portion, or back of the grate, over which the products of combustion pass to the flues, is made so that it can be rocked independently of the rest of the grate, being actuated and constructed in the usual manner, the bars being supported at right angles to those forming the front portion of the grate. Fixed to the top of the furnace and projecting downwards is a deflector placed about midway between the two portions of the grate, so causing the unburnt gases from the front part of the grate to be thrown down upon the second part of the grate, the fuel upon which is in a looser and freer, and therefore a brighter state, owing to the rocking action of the bars. Two claims are made, embracing the arrangement of furnaces substantially as described, and with modifications.—No. 17727. November 4th, 1890. 6*d.*

Presses.—*A. M. Clark, London.* (*W. C. Spelman, New York, U.S.A.*).—The object of the invention is to construct a press for effecting the forming and punching of corrugated strips of metal at one operation. In the annexed illustrations Fig. 1 is a front

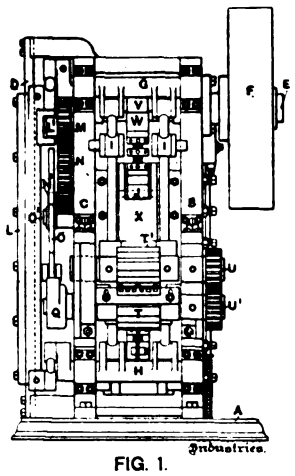

FIG. 1.

elevation, Fig. 2 a side elevation, and Fig. 3 a side sectional elevation of a machine embracing the principle of this invention. Fixed to a base A are three uprights B C D, carrying the main driving shaft E driven from F, and also two pairs of rocking shafts G H, the upper pair being connected by means of toggle-joints to the cross-head I and block J, supporting as shown (Fig. 3) the upper corrugating block K, the lower pair being also connected by toggle-joints to a suitable block carrying the lower corrugating block K^1. Sliding in D is a slide-box L, carrying at each end gudgeons pivoted to toggle-joints connected to the two pairs of rocking shafts G H. The slide-box is raised and lowered so as to revolve the shafts G H, and so actuating K K^1 by means of a block L^1 and crank L^2 fastened to a cog-wheel M on the end of shaft E. Gearing with M is a second cog N carrying a pin N^1 moving in a slot in a lever O, pivoted at O^1, so moving the latter backwards and forwards. The opposite end of O is connected by means of an adjustable connecting rod P to a loose ring Q carrying a pawl R working in a ratchet wheel on a spindle S. Thus by the movement of O the wheel on spindle S is revolved. Fixed on S is the corrugating wheel T (Fig. 3), gearing with and placed above which is a second corrugating wheel T, whose shaft is suitably connected to that of T by gear wheels U U^1. The punching operation is effected by a crank V on the shaft E, attached to which is an adjustable rod W, pivoted to the block X carrying the punching device Y. The device Y passes through holes in K K^1, and is so operated that this is effected whilst K K^1 are together. Claims: (1) In a machine for corrugating and "truing" metallic strips, the combination of the corrugating rollers with the corrugating plates, and with means, substantially as described, whereby said corrugating rollers are brought into motion when the corrugating plates are separated, and remain at rest when said corrugating plates are brought together, as and for the purpose set forth; (2) in a machine for corrugating, "truing," and

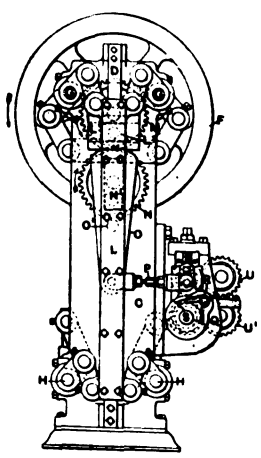

FIG. 2

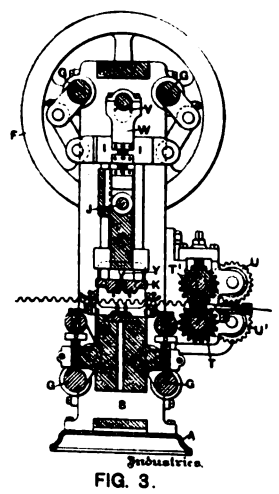

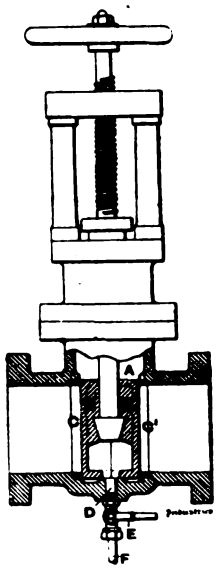

FIG. 3.

perforating metallic strips, the combination of the corrugating rollers with the corrugating plates, and with a punching device, and with means, as described, whereby said corrugating rollers are brought into motion when the corrugating plates are separated, and remain at rest when said corrugating plates are brought together, and with means, substantially as described, whereby said punching device is passed through and wholly withdrawn from the corrugating plates whilst the same remain together, as and for the purpose set forth.—No. 16772. October 21st, 1890. 8*d.*

Textile Machinery.—*F. Garniss, Manchester.*—The invention relates to the bearings of the vertical spindles of "slubbing," "roving," winding, doubling, and intermediate frames used in the preparation of textile fibres, the object being to provide an automatic self-adjusting top bearing. This improved sleeve bearing is formed in two parts, consisting of an upper and a lower tube. The lower part is bored to clear the spindle, and is formed with a collar at the top. The usual jamb nuts are applied beneath to secure it to the upper rail. The interior of the collar is hollowed out to form a socket to receive and fit a rounded or ball-shaped nose on the upper part of the bearing. This upper part is bored to fit the spindle accurately, and is connected to the lower part by a union ring or coupling which screws upon the collar of the latter, and so confines the spherical nose of the upper part in the socket of the lower part, the two parts being thus connected by a ball and socket joint, which allows the upper part to move freely relatively to the lower part. Claims: The improved mode of mounting the spindles of roving, slubbing, winding, doubling, and intermediate frames used in the preparation of textile fibres substantially as described.—No. 574. January 13th, 1890. 6*d.*

Stocks for Boring Bits.—*J. Gutmann, Frankfort-on-the-Main, Germany.*—The stock constructed according to this invention consists of a circular block having attached to one end of it centrally a suitable shank, and having a hole of a suitable depth formed in its other end. Radially converging grooves are formed in the inner periphery of this block, in which slide wedge-shaped blocks. The outer ends of these wedges rest on the face of a nut or cap which screws on to the end of the circular block. The wedges are held against the face of the block as follows:—Working in a small hole leading centrally from the back of the larger hole in the circular block is a spindle, on the outer end of which is a disc held against the inner ends of the wedges by means of a spiral spring around the spindle attached to the disc. From the above it will be seen that, by placing the shank of a boring-bit into the hole in the circular block, and then, by means of the nut screwed on to one end thereof, forcing the wedges into the converging guide grooves, the wedges will be caused to close on the said shank, so holding it firmly. Four claims are made, embracing the construction of a stock for boring bits substantially as described.—No. 2509. February 15th, 1890. 6*d.*

Steam Valves.—*M. H. Robinson, Kingston-on-Thames, Surrey.*—The object of the present invention is to ensure perfect tightness in stop valves for steam and other pipes. The accompanying illustration shows a cross-section of a stop valve embracing

the modification of this invention. A is the body of the valve, B B^1 are valves pressed outwards against the faces C C^1, D is the leak hole closed by a cock E to which a drain pipe F is shown connected. If B be the valve exposed to the higher pressure, it is evident that leakage past it will be carried away by the pipe F, and will not be able to establish a leak past B^1 as well. The cock E may be used also as an ordinaay drain for removing water of condensation. Claims: (1) The use of a leak-hole with suitable means of closing the same, in the body of a valve having two working faces, so arranged as to carry away any fluid which may leak past one of the faces (when the valve is closed) into the space between the two faces; (2) the combination of two valves of any kind in one casting, or otherwise in immediate connection with each other, with a leak-hole from the space between the two valves; (3) the use of a leak-hole in valves, arranged substantially as and for the purpose set forth.—No. 1958. February 5th, 1890. 6*d.*

Pipe Wrenches.—*T. W. Fisher, Helena, Montana, U.S.A.*—The shank of the wrench is formed at its forward end with a fixed jaw, and an adjustable jaw is formed in one with a head or carrier fitted to slide along the shank, and is moved along same by means of a rack bar fitted to it. This bar is fitted to slide on the shank and is pivoted at one end to the handle, which in turn is pivoted to the shank. This handle thus forms a lever by which to throw the rack bar and the movable jaw backwards and forwards according to the direction in which it is moved. The handle, and so the rack, is normally held in its forward position by means of a spiral spring interposed between the handle and a projection on the end of the shank. The movable jaw-head is connected with the rack bar by a spring-pressed locking toothed catch pivoted to the jaw-head within which it is received, a thumb piece being provided by means of which the catch may be pressed out of engagement, so allowing the jaw head to be adjusted to suit the size of the pipe. Two claims are made, embracing a pipe wrench consisting of a wrench shank, having a jaw at its outer end, and another jaw fitted to slide upon the shank by means of a handle lever pivoted to the inner end of the shank, a bar pivoted to the handle lever adapted to move the sliding jaw, and an engaging and disengaging device between the sliding jaw and bar adapted to provide for the independent adjustability of the sliding jaw, substantially as described.—No. 2639. February 18th, 1890. 8*d.*

Digitized by Google

PIT CAGES.—*J. Dustin & W. Thomas, both of Moss Bay, Workington, Cumberland.*—This invention refers to a method of connecting wire ropes to pit cages or other objects, and consists of an internally conical shaped box with double eyes at its upper end, by means of which it can be fixed to the cage. The wire rope is put through the small end of this conical box, and a tapered pin is driven into the centre of the wire, thereby jamming the strands of the wire against the sides of the box. When once the wire gets a weight on it, it will further tighten itself, and cannot possibly be drawn through the hole. Claims: Simplicity and cheapness of construction. The improved means for connecting wire ropes to pit cages or other objects saves a great deal of time, it being capable of being connected in a few minutes as there is no lapping of the rope with copper wire or riveting to be done.—No. 9689. June 23rd, 1890. 6*d.*

HYDROCARBON ENGINES.—*C. D. Abel, London.* (*The Gas Motoren Fabrik Deutz, Köln-Deutz, Germany.*)—Referring to the annexed illustrations, Fig. 1 is a side elevation, Fig. 2 an end

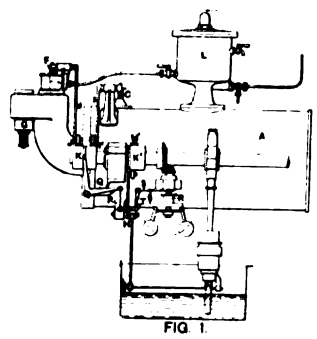

FIG. 1.

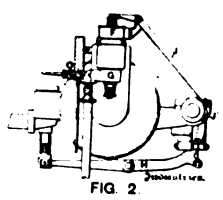

FIG. 2.

elevation, Figs. 3 and 4 sections through the cylinder, and Fig. 5 section through the oil spray and mixing apparatus of a hydrocarbon engine constructed according to this invention. The piston of the cylinder A in its reciprocating motion leaves a charging and compressing space to which is fitted the escape valve B, air supply valve C, and an igniting passage D, containing the igniting tube E, the valve F for the admission of oil spray, and also a self-acting air valve G. The valves B, C, and F are actuated through levers H, I, and J, from cams H^1 I^1 J^1, on sleeves K K^1, revolving on the way-shaft K^2. Oil is supplied to the pressure regulator L, and passes from thence to the regulating screw valve M (Fig. 5); thence it passes to the supply valve F. As the suction stroke of the piston commences the valve F is opened, and, the valve G opening automatically, the air enters, and, passing at a high velocity through nozzles N and N^1 formed around the end of valve F (Fig. 5), mixes with the oil spray supplied by F. During the suction stroke the valve C is also opened, so allowing air to pass into A and mix with the mixture of air and oil therein. During the return stroke the mixture of oil and air is compressed, and at the end of the stroke it is ignited by tube E supplied with gas from pipe O. The piston is thus forced outwards, and during the return stroke forces the result of the combustion out through valve B. For the purpose of regulating the speed of the engine the regulating sleeve K, which is moved to and fro by means of the lever H that works the escape valve and by the link P and lever Q, is held in its one end position

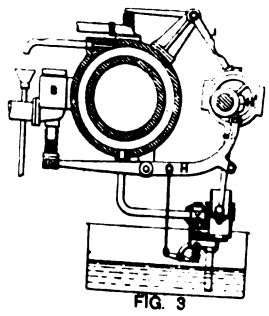

FIG. 3

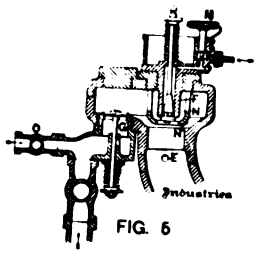

FIG. 6

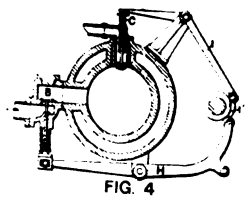

FIG. 4

corresponding to the opening of the escape valve B by the action of the governor R, lever S, and notch T, so that the cams I^1 and J^1 revolve out of gear with the levers I X J when the speed of the engine is too great, in consequence of which the oil valve F and the air valve C are kept closed in a similar manner to that described in the previous application No. 20892 of 1889. In a similar manner the suction valves of a pump U are closed, the pump being operated by means of an eccentric, as shown (Fig. 3), from K^2, and is for the purpose of supplying water to the cooling jacket of A. Six claims are made.—No. 1943. February 5th, 1890. 8*d.*

LATHE CHUCK.—*J. Gutmann, Frankfort-on-the-Main, Germany.*—The object of the present invention is to provide a chuck for boring tools, whereby the latter can be easily and rapidly centred. For this purpose the inventor uses a metal ball of a suitable size having conical-shaped holes of different sizes formed therein to receive the tapered shank of the drill. This ball is held as follows:—A cylindrical block, having a central shank whereby it can be attached to a lathe, has screwed to its end a cap or nut having a hole formed in it of a somewhat larger diameter than that of the shank of the drill to be carried. The opposite faces of this block and its cap are recessed to receive the ball carrying the drill. It will thus be seen that when "truing" the drill it is only necessary to unscrew the nut on the cylindrical block sufficiently to allow the ball to move with a moderate amount of friction. After truing the nut is tightened up, so holding the ball, and consequently the drill, rigidly. Claims: A chuck for holding boring bits and for accurately embracing the same, constructed substantially as described (in two claims). —No. 2545. February 17th, 1890. 6*d.*

LOOMS.—*F. Leeming & R. Wilkinson, both of Bradford.*—The invention relates to the construction and combination of parts connected with the dobbies or shedding mechanism of looms. On the pin in the end of the shedding or "jack" lever, a combined connection and guide is mounted, having a cam surface or slot formed therein, one end of which is connected to the healds. A cross shaft fixed to brackets on the loom frame passes through said cam slot. When the "jack" levers are operating, raising and lowering the healds, the guides are also raised or lowered, and by reason the cam slot and fixed cross-rod are raised or lowered in a perfectly vertical direction, and one of such guides and cam slots being attached to the end of each "jack" lever, the healds also are raised and lowered vertically, so that better results in the weaving are obtained. Claims: The guide connecting link having a cam surface or slot, a cross-rod or shaft, and an adjustable lug, all in combination with a "jack" or shedding lever, as and for the purpose described.—No. 2800. February 21st, 1890. 6*d.*

LOW PRESSURE OR CONDENSING ENGINES.—*J. Darroch, Springhill, Windsor Crescent, Newport, Monmouthshire.*—This invention refers to improvements in low-pressure or condensing engines, and has for its object to facilitate the working thereof by disposing to as great an extent as possible of air which is readily absorbed by the water of condensation. Referring to the annexed illustrations Fig. 1 is a sectional elevation of an air pump, hot well, and feed plunger pump, Fig. 2 being a half-sectional elevation of the upper portion of Fig. 1 taken at right angles. A is an air pump barrel, B the bucket, C the hot well, D the overflow, E the feed plunger pump, having the valves F all arranged in the usual way. The parts which constitute this invention are the pipe or port G connecting the upper extremity of the air pump barrel with the hot well and the valve H on or in connection with

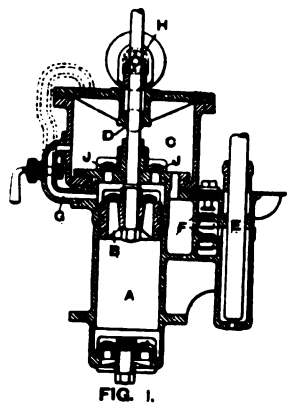

FIG. 1.

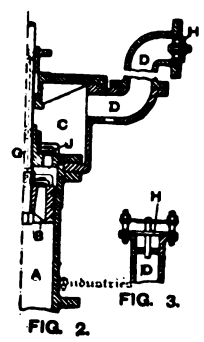

FIG. 2.

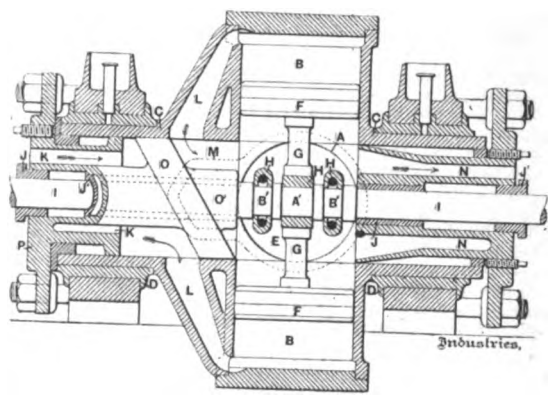
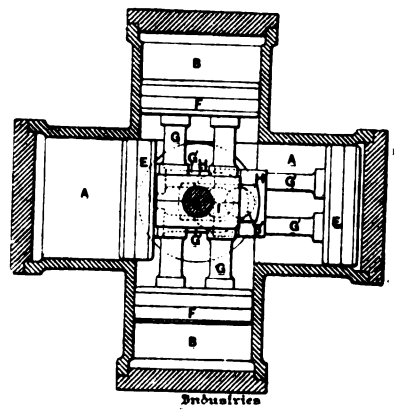
FIG. 3.



the overflow pipe D of the hot well. The operation of the apparatus is as follows:—At each upstroke of B a volume of water and air is discharged through the head valves J into the hot well, but in performing this operation the stratum of air lying between the surface of the water overlying the bucket and the head valves is more or less compressed, causing air cushioning and knocking of the engines. The water and air thus discharged to the hot well may be then transferred by the pump E to the boilers, the displacement in the hot well being accompanied by a further inrush of air from the atmosphere through the open end of the overflow pipe D. By means of G and valve H the inrush of air aforesaid is prevented on account of the action of the downstroke of the air pump bucket automatically closing the valve H, and on the upstroke the stratum of air overlying the water below the head-valves finds free egress through G to the hot well and thence (under the action of the upstroke of the air pump bucket) through the automatic valve H to the atmosphere. Claims: (1) In condensing engines connecting the upper end of the air pump barrel with the hot well by means of a pipe or port G for the purposes set forth; (2) in combination with an air pump and hot well, the arrangement or combination of parts consisting of the pipe or port G and valve H on the overflow of the hot well; (3) the arrangement or combination of parts constituting the improvements in low-pressure or condensing engines, substantially as and for the purposes described.—No. 5952. April 19th, 1890. 8*d.*

PRINTING MACHINES.—*J. Kelley, Otley, Yorkshire.*—The invention embraces improvements in the method and apparatus for mounting, lifting, and connecting the cylindrical flyer apparatus of printing machines. Instead of the usual framework, the inventor fixes on each cylinder stand a perpendicular pillar, of small section, in such a position as to cause no obstruction to the operator. The two side presses which contain the flyer apparatus are prepared with long bosses, which embrace these pillars, and guide the apparatus in its reciprocating motion. Across the top of the pillars, in suitable bearings, is mounted a shaft, on which are fixed a hand-wheel, two pulleys of equal size, and also a larger one. To the first-named pulleys are connected chains, which are also connected to the flyer apparatus, and to the larger pulley is attached a chain and weight, which, acting together with the other pulleys, facilitate the lifting of the flyer, which is effected by means of the hand-wheel. The cam bar for actuating the flyer the inventor places in such a position that it is away from the flyer and out of the way of the operator. This is effected by means of an intermediate bar with a toothed rack attached at such a position thereto as to gear with a toothed wheel on the flyer shaft. This intermediate bar may be placed in a horizontal position supported by suitable bearings, and to be lifted at the opposite end to that of the rack. The free end of the said bar is so arranged as to be automatically engaged with and disengaged from the cam bar, and when in operation the cam bar imparts motion to the flyer through the intermediate bar. Three claims are made.—No. 1374. January 27th, 1890. 8*d.*

LOOMS.—*J. Hall, London.* (*A. Lockwood, Meerane, Germany*).—The invention has for its object the application of an automatic combined fast and loose reed action to looms. A cam fixed on a crank-shaft communicates an oscillating motion to a pivoted lever the end of one arm of which has a projecting part, which, during the inward oscillating of the lever, comes against a bar carried on a second shaft. The shaft, when contact or engagement is effected, is caused, by reason of the action of the cam and consequent oscillation of the lever, to slide laterally, carrying with it a number of arms fixed thereon and fitted with steel pins, so as to disengage these from the reed locks and thereby convert the loom from a fast into a loose reed loom. As soon as the bar has got to the end of its stroke, communicated to it by the oscillating lever, a helical spring on the sliding shaft brings it back again so as to re-engage the locking pins in the reed locks to convert the loom from a loose reed into a fast reed loom, until the oscillating lever is brought to perform another inward stroke. During the loose reed action the reed holder is held in position by a spring. Two claims are made.—No. 2809. February 21st, 1890. 6*d.*



ROTARY ENGINES.—*O. Kohn, Wiener Neustadt, Vienna, Austria.*—Fig. 1 in the annexed illustrations is a sectional elevation, and Fig. 2 a section through the cylinders at right angles to Fig. 1 of an engine constructed according to this invention. Two pairs

FIG. 1.

of cylinders are used, A being one pair and B the other, formed substantially as shown, and with hollow trunnions C revolving in bearings D cast to them. E are the pistons of A, and F of B. The pistons E and F are connected by rods G G^1 respectively to their crank-pins A^1 and B^1, by means of sliding blocks H. The crank-shaft I runs in bearings J J^1, the latter bearing serving also as the glands of the crank-shaft stuffing boxes. K is the main steam supply port, and L L^1 the subsidiary ports to the cylinders B, the subsidiary ports M to B being indicated by dotted lines. N is the common exhaust, the direction of the steam being indicated by arrows. O is a stationary elliptical disc

FIG. 2.

connected to the cover P by means of sleeve O^1, and by means of which the steam distribution is effected as the cylinders revolve about it, as will be readily understood. Three claims are made, embracing the construction of a rotary steam engine substantially as described.—No. 2044. February 7th, 1890. 8*d.*

TUBE EXPANDER.—*D. Jones, Inverness.*—The invention relates to the fixing of tubes in plates, such as boiler tube-plates, the method being that first an annular V or other shaped groove is formed in the peripheral surface of the hole in the tube-plate, and then expanding the tube when in the hole so that it will fill the said groove. The apparatus for preparing the holes comprises a spindle or cutter-holder adapted to be secured to the tool spindle of a drilling or boring machine. This holder is made with a slot, wherein is pivoted a bell-cranked lever, having at one end a cutting edge, the form of which will depend upon the shape to be imparted to the surface of the hole. This cutting edge, and that arm of the lever on which it is formed, is normally within a longitudinal recess formed in a reduced part of the holder, which part is of such a diameter as to fit the hole in the tube-plate. A second recess is made in its reduced part of the holder for the escape of the cuttings. The other arm of the bell-cranked lever, which normally projects outwards at right angles to the spindle, has hinged to it one end of a screwed rod, the opposite end of which passes through a hole in a small bracket or lug fixed to and projecting from the upper part of the spindle. Screwed on to this screwed bolt is a hand-wheel arranged to work against the face of the lug or bracket, and by revolving which in a direction tending to screw it off the bolt the bell-crank lever would be so actuated that its cutting end would be caused to stand out of the recess in the cutter-holder or spindle, so that

Digitized by Google

as the whole is revolved it would cut a groove in the peripheral face of the hole in the tube-plate. When screwing the hand-wheel in the opposite direction the cutting end would be caused to recede into the groove in the spindle by means of a spiral spring, one end of which is connected to the lug or bracket, and the other to one arm of the bell-crank lever. The tube expander for expanding the tubes in the holes formed with annular grooves as described comprises three segmental blocks held within two loose rings in grooves therein, and mounted upon a tapered mandrel by which they can be expanded and rotated. Each block is formed with an external curved ridge adapted to expand the tube into the annular grooves in the hole in the tube-plate, and with a flange so curved at one side as to cause the projecting end of the tube to be beaded over to the required form when rotated in contact with such end. The end of the tube is reduced before being placed in the hole in the tube-plate preparatory to being expanded. Claims: (1) Reducing the tube end, expanding it by means described into a hole previously prepared as described, and beading over the end portion of the tube projecting beyond the tube-plate as described; (2) for grooving the holes in tube-plates to receive tubes: the apparatus constructed substantially as described.—No. 774. January 15th, 1890. 8*d*.

Drills.—*H. Hilditch, Whitmore Reans, Wolverhampton.*—The object of the inventor is to construct a drill by means of which holes, with inwardly increasing diameters, may be drilled. A pair of fingers or arms, pivoted in a jaw on the end of a holder carried by the spindle of the drilling machine, are formed with a cutting edge down one side, the two fingers together forming a divided cutter, the diameter of which can be increased as desired by causing the lower and cutting ends of the fingers to cross one another more and more. The upper ends of the fingers are continued beyond the fulcrum, and a rubber band is placed around them to tend to draw them, and thus the lower ends, together. A conical collar is screwed upon the shank of the tool holder above the jaw wherein the arms or fingers are fulcrumed, by causing which to descend the conical surface would be brought between the upper ends of the fingers, so causing them and the lower ends to be gradually forced apart, and increasing the diameter of the drill. The tool described may be used for under-cutting a cylindrical hole, or may be used for forming a hole with inwardly increasing diameters, in which case the ends of the fingers are also formed with cutting edges. Three claims are made, embracing the construction and operation of drills substantially as described.—No. 2548. February 17th, 1890. 8*d*.

Polishing Lathes.—*J. C. Dalman & E. J. Blincoe, both of Birmingham.*—The invention relates to the bearings or double bearings of spindles, axles, and shafts of polishing, buffing and other lathes. According to this invention the two arms of the headstock are bored axially, and placed into these holes are adjustable and inside-coned shaped bearings. The enlarged taper ends of these bearings are directed inwardly. Fixed on the spindle carrying the buffs, bobs, or polishers are two coned collars placed with their larger ends opposite. These collars are placed at such a distance apart that when the spindle is in position the collars run in the adjustable inside-coned bearings. Passing through the arms of the headstock are suitable set screws, the ends of which, coming against an inclined face formed on the outer periphery of the inside-coned bearings, tend to force the latter inwards, so tightening it upon the coned collars of the spindle. Claims: (1) Providing the spindles, axles, &c., of polishing and other machinery with adjustable coned bearings, consisting of fixed collar cones working within adjustable or she-cones held in the hollow heads of the framing of the machinery as described; (2) in adjustable coned bearings consisting of fixed externally coned collars working in conical bearings, made separate or in one piece with the framing of a machine, all constructed, arranged, and working substantially as described; (3) the combination, with adjustable coned bearings of an inclined sided recess, wherein the point of the set screw "takes" for bringing the coned sleeve up to its bearing as described.—No. 3051. February 26th, 1890. 8*d*.

Tube Connections.—*R. W. & T. S. Lewis, both of Wolverhampton, & W. H. Lewis, Goldthorn Hill, Wolverhampton.*—The ends of the tubes are flanged or turned back at right angles, and these flanged ends are joined together in the following manner. Between the flanges of the tubes a cast or wrought iron or other metal ring is placed, having a T-shaped cross section—that is, a flat ring which has projecting from its outer periphery at each side, and at right angles to it, a flange. This ring is of such a size that when placed between the tubes the flanges thereof project over the flanges of the tubes, so preventing the two rings of packing placed at each side of the ring being blown out. To press the two flanged ends of the tubes together a loose gripping ring is placed on each tube behind the flange on the end thereof; these gripping rings are drawn together, so tightening the flanges of the tubes together between them by means of screw bolts and nuts. The inner side of each of these gripping rings is provided with a projecting boss of the same depth as the flanged ends of the tubes, by means of which bosses the rings when drawn together in forming the joint press the flanged ends of the tubes against the collar placed between them. Three claims are made, embracing the arrangement as described, with modifications.—No. 12476. August 9th, 1890. 8*d*.

ELECTRICITY.

Railway Conduits and Conductors.—*C. J. Van Depoele, Lynn, Massachusetts, U.S.A.*—The invention relates more particularly to the use of tubular conductors and of conduits therefor. In one form the conduit comprises a flat metallic base-plate, upon which are secured at suitable distances apart suitable side brackets. To the inner and opposite side of these brackets are secured hollow U-shaped side pieces, which are set up edgewise upon the base-plate, and so secured. The opposite projecting arms of these side pieces do not meet, the slot above being for the insertion of the collector, which consists of two insulated metallic plates clamped together and with the ends tapered. This collector runs between two tubular conductors fixed in the recesses in the U-shaped side pieces. The conductors are coated with some non-conductive material, and holes are formed at suitable distances apart in their opposite sides. In these holes, which are screw-threaded, are screwed suitable insulating collars, the inner ends of which project some distance into the tube. Sliding in these collars are metallic pins of a length slightly greater than the diameter of the tube conductors, having suitable heads formed on each end thereof. Between the outer ends of these pins and the insulating collars are placed helical springs, which tend to force the pins outwards, so keeping their inner ends from contact with the opposite internal side of the tube, except when they are forced inwards by the collector passing between the tubes. The inventor also describes several modifications of the above arrangement. Six claims are made.—No. 15084. September 24th, 1890. 8*d*.

Electromotors.—*M. Leblanc, Paris, France.*—This invention relates to the construction and arrangement of electromotors to be worked by alternating currents. Fig. 1 is a vertical section and Fig. 2 a part section of the ring and part end view of a motor embracing the object of this invention, the field magnets being excited by a continuous current, and the armature by an alternating current. Fig. 3 is a diagram showing the method of transmitting the continuous and alternating currents by the same

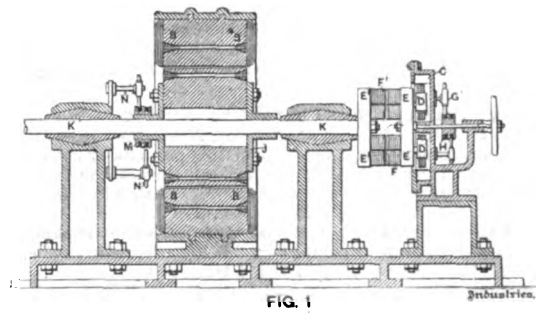


FIG. 1

conductor. In Fig. 2 A is a Pacinotti ring with teeth parallel to the axis; it is made of a number of iron sheets separated by insulating material and held together by bolts insulated by ebonite sleeves B (Fig. 1). The coils are connected to the segments of a commutator C in the same manner as in multipolar continuous current machines having only one pair of brushes. The brushes D are caused to revolve by the disc E carrying the electromagnets F. The continuous current is supplied by the rubber G on the revolving disc H to the electromagnets F, whence it passes by one of the brushes D to the coils on A, returning by the other brush and the disc H^1 and rubber G^1. The armature of this machine is made like the ring L of iron sheets bolted together and carried on discs J keyed on the shaft K of the machine. Six coils A are traversed by the continuous current so that the cores of all the odd coils present the one polarity and those of the even present the opposite polarity. The entering wire of the first is connected to a disc M, and the leaving wire of the last to a disc M^1; on these discs bear the brushes N N^1, which conduct the alternating currents for the armature. As the electromagnets F cannot act concurrently on the armature, a disc E^1 fixed on the shaft K facing the disc E carries a set of electromagnets F^1, the coils of which are

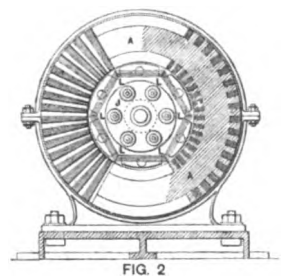

FIG. 2

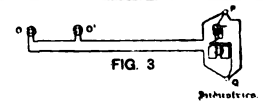

FIG. 3

traversed by the same alternating currents as those of the armature, so that the forces developed between them and the magnets F are the same as they would be if developed between the coils of the armature and the magnets F. In a modification the inventor describes a motor of the disc form, arranged according to this invention. Referring to Fig. 3, O is the continuous current generator, and O^1 the generator of alternating currents connected in series in one circuit to the terminals P Q, from which there are two branches, the one including the induction coils of the motor and the other its armature coils, this latter being intercepted by a condenser. Claims: (1) In an alternating current electromotor the combination of an armature and a coiled ring provided with collector and brushes revolving synchronously with the generator of the alternating currents, as described; (2) the method of transmitting by the same conductor the continuous currents for exciting the inductors of the machines and the alternating currents for their armatures, and of separating these currents at the place of their application into two branches, the one for the inductors including a coil of small resistance, but high self-induction, the other for the armatures including suitable condensers.—No. 19450. December 3rd, 1889. 8*d*.

CHEMISTRY.

Production of Tartaric Acid and Cream of Tartar.—*A. Martignier, Montpellier, France.*—This invention relates to a method for the extraction of tartrate of lime contained in lyes, argals ("Sablons"), and other tartarous matters and its transformation into cream of tartar and tartaric acid, the method being based upon the fact that when tartrate of lime is added to a saturated solution of sulphate of potash there is formed neutral tartrate of potash and sulphate of lime according to the following equation:—

$$C_4H_4CaO_6 + 4H_2O + K_2SO_4 = C_4H_4K_2O_6 + CaSO_4 + 4H_2O.$$

The lyes or other tartarous matters finely pulverised are treated with a saturated solution of sulphate of potash, the treatment taking place cold, under ebullition or pressure, according to the quantity of material being treated. If the lyes contain bitartrate of potash it must be neutralised with chalk. The reaction being terminated, the residuum containing the sulphate of lime and the insoluble matters is separated from the liquid containing the neutral tartrate of potash and the excess of sulphate of potash, by decantation or otherwise. The liquid is then decolorised by animal charcoal and treated with an equivalent quantity of sulphuric acid, which, in precipitating nearly the whole of the bitartrate of potash, regenerates the half of the sulphate of potash entered into the reaction. The cream of tartar thus precipitated is purified, and for the manufacture of tartaric acid transformed into tartrate of lime in the usual manner. The sulphate of potash, when it may be done with advantage, may be replaced by sulphate of soda, the process being slightly modified. Claims: (1) The extraction of tartarous compounds contained in lyes, argals, tartars, and other tartarous matters, and their transformation into cream of tartar by the use of sulphate of potash as described; (2) the extraction of tartarous compounds as above set forth, and their transformation into cream of tartar or tartaric acid by the use of sulphate of potash or soda, and by a mixture of both.—No. 20078. December 13th, 1889. 6*d*.

MISCELLANEOUS.

Lubricators.—*C. Muellor, Boston, Massachusetts, U.S.A.*—Fig. 1 in the annexed illustrations is a vertical section of a lubricator constructed according to this invention, Figs. 2, 3, and 4 being details thereof. The oil vessel A, preferably of glass, has an opening formed in its upper and lower parts as shown,

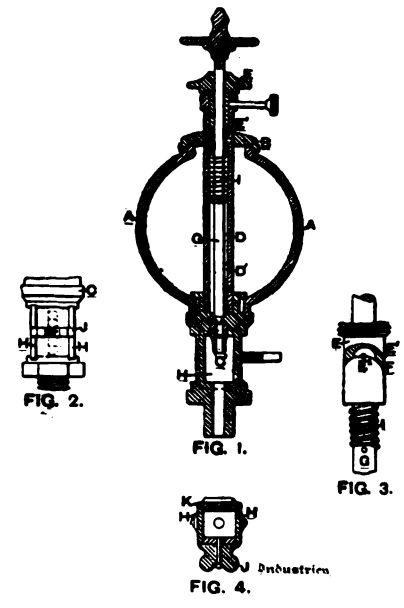

FIG. 2. FIG. 1. FIG. 3. FIG. 4.

which are normally closed by covers B C. Screwed into C is a tube D, having suitable feed-holes D^1, which pass up through A and B. Screwed into the top of this tube is a hollow regulating plug E, having its lower part made plain (Fig. 3) and provided with a slot E^1 having at E^2 a notch to receive a pin F on a spindle G extending through E and D. The lower end of G is conical, so as to close an opening in C leading through a nozzle C^1 into a chamber H. A spiral spring I on G between a pin passing through the latter and the end of E tends to force G downwards and so close the hole in C. Two opposite sides of the chamber H are made of glass, the said sides forming sight-windows, which are removable, but are normally locked in place by the thumbscrew J pivoted on one side of the chamber and having arms which extend beyond the edge of the said side and fasten the removable windows in place, the rear edge of the said windows abutting against the projecting edges K of the opposite sides, which are cast on C (Fig. 4). From the above it will be seen that the feed may be regulated by revolving E, and the supply may be cut off by slightly turning G, so moving the pin therein out of the notch, and, owing to the slanting of the slot E, to allow G to descend. Two claims are made.—No. 16610. October 18th, 1890. 6*d*.

Paper Pulp Boilers.—*C. A. Davies, Manchester.* (*C. Kellner, Vienna, Austria.*)—The invention relates to lining such boilers with a material that will resist the action of the acid or corrosive solutions employed in the manufacture of paper pulp. For this purpose the inventor applies to the boiler after it has been put together a layer or coating of an acid-resisting cement, in place of the lead lining hitherto used. Portland cement mixed with fine sand in about equal proportions the inventor has found suitable for the above purpose. Claims: In the manufacture of paper pulp the use of a jointless and seamless lining for the boilers therein employed of Portland or other acid-resisting cement or composition in place of the lead lining hitherto generally employed.—No. 2064. February 8th, 1890. 4*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE CHIGNECTO SHIP RAILWAY.

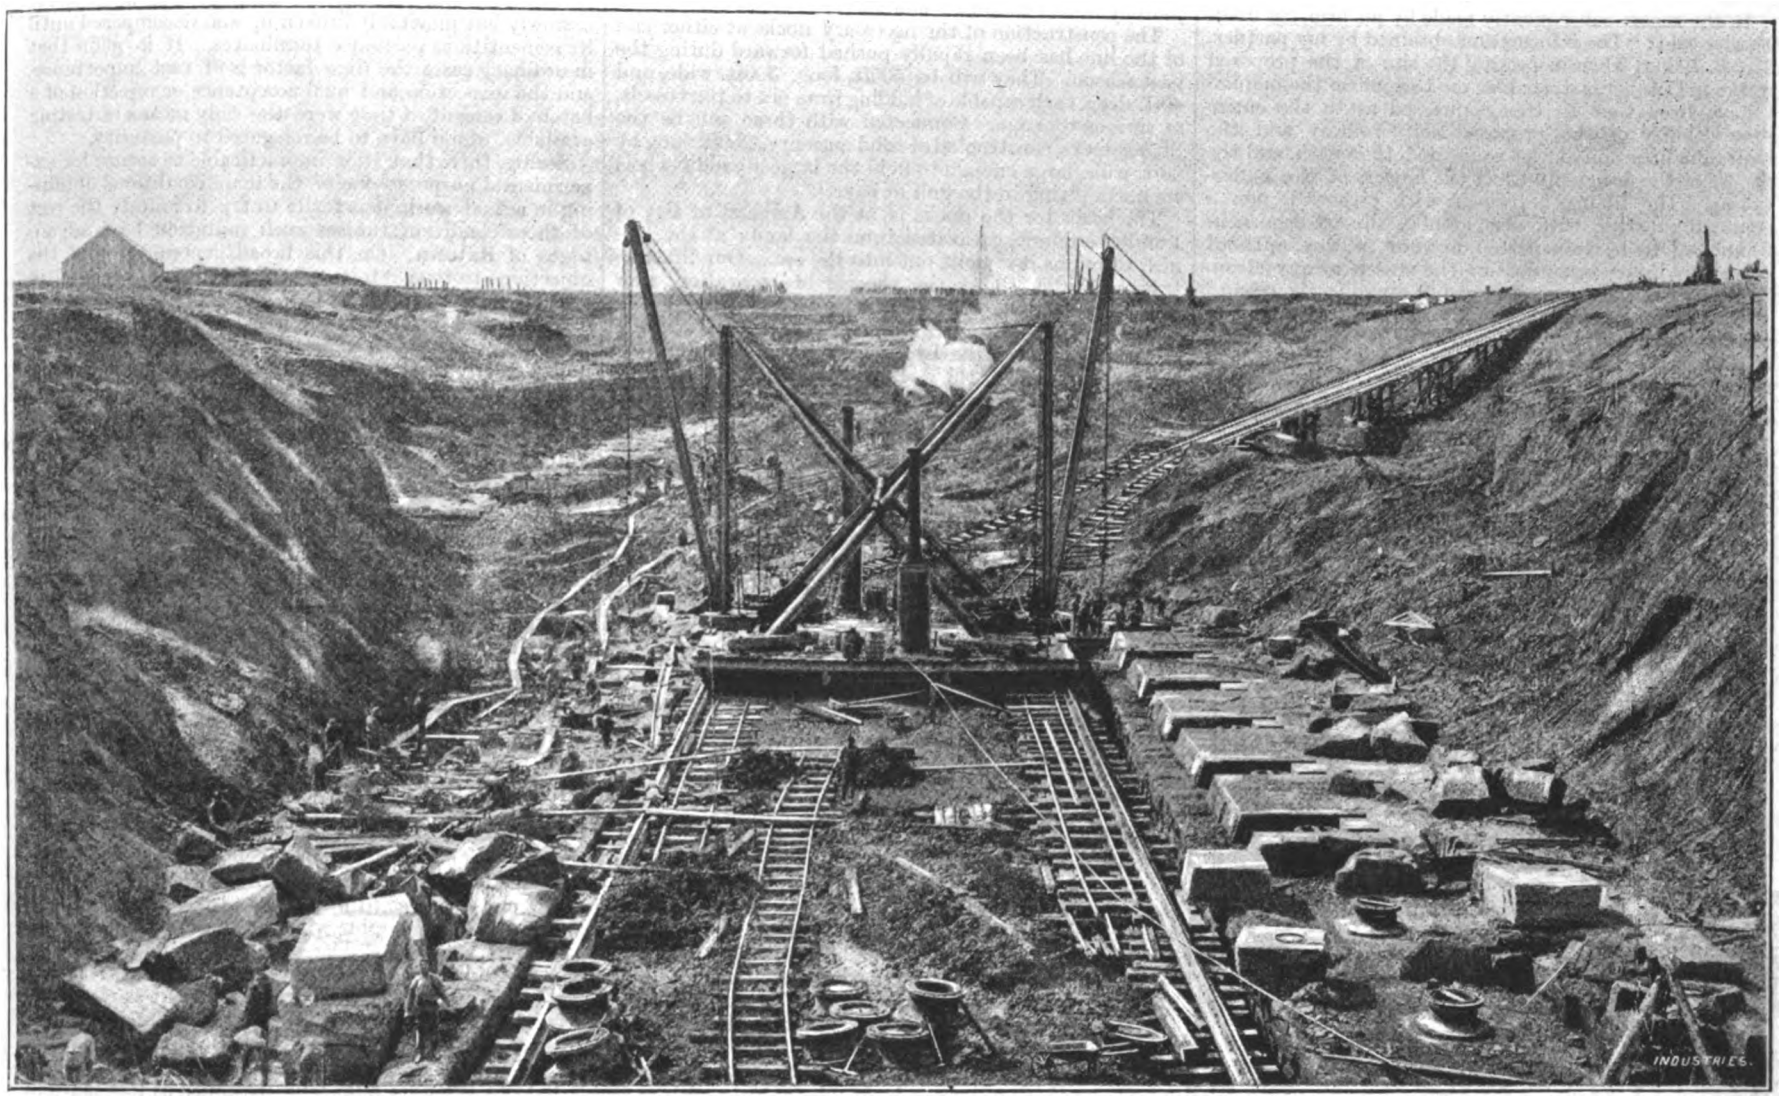

Fig. 1.—Excavation of Dock Basin at Amherst, with the Masonry of Lifting Dock in the Foreground.

THE CHIGNECTO SHIP RAILWAY.

I.

The construction of a ship railway for the transport of vessels across the Isthmus of Chignecto, which separates the Gulf of St. Lawrence from the Bay of Fundy, was begun in the autumn of 1888, and has been prosecuted with so much vigour that it is expected to be in full operation before the end of the present year. Canada will thus be able to claim the honour of being first in submitting to the test of practice an idea which has been much talked of for some years. Both from a commercial and an engineering point of view the enterprise is of very considerable importance, and as it approaches completion attracts an increasing amount of public attention.

Should this bold undertaking be crowned with anything like the success which its promoters anticipate, there can scarcely be any doubt that it will lead to a further application of the principle. To shorten routes is an object upon which no effort or expense is spared in these days, and it is not difficult to imagine the ship railway becoming to ocean transport what the Mont Cenis Tunnel or the Forth Bridge is to transport on land. Already in Canada the idea is seriously entertained of connecting the waters of the Georgian Bay with those of Lake Ontario in a similar way, by which a saving in distance of more than 400 miles will be made by vessels coming from the upper lakes. When we read, in the last Canadian statistical record, that the tonnage which comes through the Sault Ste. Marie Canal is already almost as great as that which passes through the Suez Canal, the possibilities of such a shortened route can be easily understood. In connection with this and like projects in other parts of America the progress of the Chignecto enterprise is watched with keen and interested attention.

When Captain Eads proposed some years since to construct a ship railway across Central America in order to connect the navigation of the Atlantic and Pacific, he seems to have carried along with him the opinion of the engineering world as to the practicability of his plans, but he failed to get for an improved scheme the large amount of capital required for a railway at Tehuantepec, where the distance to be crossed was 135 miles. The primary experiment of the kind was to be made under more favourable conditions.

The Chignecto Ship Railway owes its inception and execution largely to the persistent energy of a Canadian engineer, Mr. Henry E. Ketchum. The fact that Mr. Ketchum secured the approval of his plans in the first instance by the chief Government engineers of the Dominion, and later by Sir John Fowler and Sir Benjamin Baker, with whom he is now joint engineer in carrying out the work, is a sufficient guarantee that his energy has been directed by skill and practical judgment.

A glance at the map, Fig. 2, on the next page, shows at once the relation of the enterprise to the large commerce, actual and potential, of the Canadian coast. The Isthmus of Chignecto connects the province of Nova Scotia with that of New Brunswick on the mainland of the continent, making a loop in the coast line of 600 miles or thereabouts. At its narrowest point the isthmus is only 17 miles wide. So serious an impediment to the trade of the coast was the circumnavigation of Nova Scotia, so slight the obstacle to a shorter route interposed by the isthmus, that many years ago an agitation was begun to secure the construction of a canal, as this was believed to be the only way of overcoming the difficulty. Several surveys were made at the expense of the Colonial Governments. One of these was conducted under the direction of Thomas Telford, founder of the Institution of Civil Engineers. The reports of this great authority furnish striking proof of the importance assigned to the question of communication nearly fifty years ago. Divergent opinions were expressed, however, by the different engineers employed as to the possibility of constructing a satisfactory canal. Some anticipated great difficulty from the diversity of level existing at times between the waters of the gulf and the bay, due both to the difference in the height of their respective tides and the hour at which high water occurs. The Bay of Fundy is 21ft. higher than Baie Verte at high tide, and 18ft. lower at low tide, while the average rise of tide at the head of the Bay of Fundy is 36½ft. and in the Baie Verte 5½ft.

It was also urged that the deposition of the sediment peculiar to the tidal waters of the Bay of Fundy, and from which the great marshes of the vicinity have been formed, would be a permanent obstacle to the maintenance of a canal. Meanwhile, public opinion became more decided as to the commercial necessity for means of communication. A Royal Commission, of which Sir Hugh Allan was chairman, and composed of delegates from the Boards of Trade of the chief cities of Canada, was appointed in 1871 by the Dominion Government, and after an exhaustive inquiry reported as follows:—"Inseparably connected with the growth of intercolonial trade is the construction of the Baie Verte Canal. . . . The advantages which must accrue, not merely to the Dominion as a whole, but to the commerce of the maritime provinces, are so clearly pointed out by the Boards of Trade of all the leading cities of Canada, and by men interested in the development of our commercial interests—not merely by the merchants of St. John and other places in the locality of the proposed canal, but merchants of Hamilton, Toronto, Montreal, Ottawa, and Quebec—that it is superfluous to do more than to briefly refer to a few of the salient features of the scheme."

It was while engineers hesitated about the canal, and commercial men grew impatient, that Mr. Ketchum first brought forward, in 1875, his already-matured plans for a ship railway, in doing which he anticipated the plans of Captain Eads. He secured such strong support from chambers of commerce, the Press, and the trading and shipping community in various parts of Canada that, when he brought the question before the Dominion Government in 1882, the Cabinet felt justified in recommending the scheme to Parliament. Sir Charles Tupper, then Minister of Railways, gave the enterprise his strenuous support, and in that year provision was made for a substantial subsidy, finally fixed at $170,300 per annum for twenty years. Sir John Fowler, after examination of the plans and estimates, expressed a decisive opinion that, from an engineering point of view, the construction and working of the line were perfectly

Digitized by Google

practicable, and consented to assume the position of engineer-in-chief. Later, Sir Benjamin Baker visited Canada to make a special and detailed examination of the proposed line and of the facilities at either extremity for the construction of the necessary lifts and docks.

In the report subsequently made by his firm, Sir John Fowler said: "The information obtained by my partner, Mr. B. Baker, when inspecting the site of the proposed works in October last, enables me to confirm the opinion I have from time to time expressed as to the entire practicability of the proposed ship railway and the hydraulic lifts and docks connected therewith, and the fitness of the designs to effect the objects of the undertaking. The lifting of vessels with cargoes is now a common practice, with even double the tonnage contemplated to be transported on your railway, without doing any injury or subjecting the vessels to any strain beyond what they were designed to stand in the ocean."

Such opinions, together with the substantial aid of the Canadian Government, soon made it possible to form a company for carrying out the work. All the land necessary for the railway was gratuitously expropriated and granted to the company by the county of Cumberland, Nova Scotia. A formal contract was signed in 1886 with the Canadian Government, and work was begun in the autumn of 1888 by John G. Meiggs & Son, the chief contractors, since which time it has been carried on continuously.

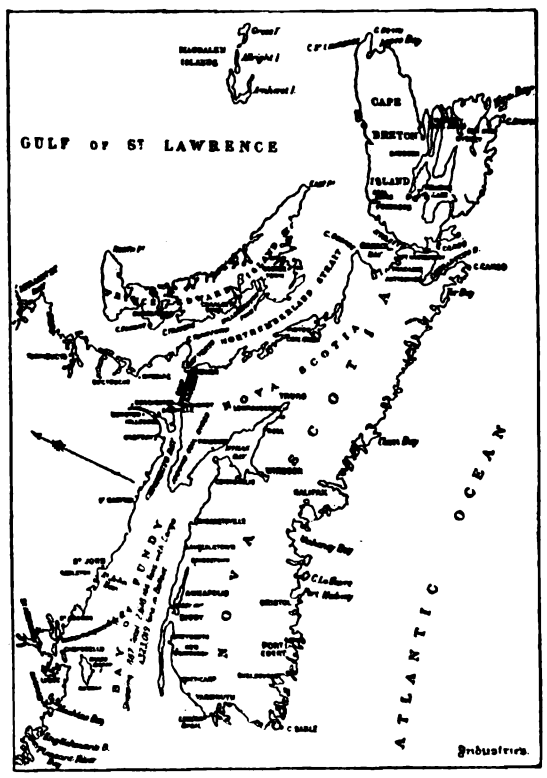

FIG. 2.

After this slight historical sketch, we may proceed to describe the chief features of the work. From the terminus at the head of the Cumberland Basin to the Tidnish terminus on Baie Verte the distance is seventeen miles. Owing to the favourable nature of the ground it was found possible to make the road perfectly straight. The gradients are light, in no case exceeding 1 in 500, or 10ft. in a mile, while, for the most part, the line is quite level. Great care has been employed to get a solid road bed. Where the line crosses the Tantramar marshes, which consist of soft mud many feet in depth, rock, borrowed for the purpose, was used for the embankment, and filled about 8ft. above grade to secure additional weight, and leave no doubt that the road was resting on hard pan. The line crosses one floating bog of moss about half a mile wide. Here the moss was excavated to the hard bottom preliminary to the construction of the embankment. Elsewhere little difficulty was experienced in finding a perfectly stable and satisfactory road bed.

In describing the track it should be mentioned that the line is constructed with the intention of carrying ships of 1,000 tons register or 2,000 tons displacement. The track is a double one, the distance from centre to centre being 18ft. The steel rails for the four lines of track are probably the largest yet made, weighing 110lb. to the lineal yard, 6¼in. in height, with spikes and fish plates heavy in proportion. The sleepers are of southern pine, 9ft. by 7in. by 12in., excepting at the joints, where they are 27ft. long, so as to connect all four rails. Stone ballast will be used throughout. The rails and other material for the permanent way have been supplied by Messrs. Cammell & Co., of Sheffield.

Four locomotives of unusual weight and power are being constructed, from special designs, at the locomotive works, Kingston, Ontario. Two of these are expected to move the heaviest ship to be taken across at a speed of ten miles per hour, thus completing the whole journey in less than two hours.

The construction of the necessary docks at either end of the line has been rapidly pushed forward during the past season. They will be 500ft. long, 300ft. wide, and 40ft. deep, each capable of holding from six to ten vessels, of various tonnage. Connected with these will be the lifting docks, constructed of solid masonry, 250ft. long by 60ft. wide, large enough to hold the largest paddle-wheel steamers plying in the gulf or bay.

The basin for the docks is, at the Amherst or Bay of Fundy terminus, excavated from the land; at the Tidnish terminus it is built out into the sea. Our illustration, Fig. 1, shows the process of excavation, now nearly completed, at the Fundy terminus, with the masonry of the lifting dock in the foreground, and the cast-steel bases of the hydraulic rams in position. At the seaward end of the dock will be a gate 60ft. wide by 30ft. high, to retain the water after the fall of the tide. Each of the lifting docks will be fitted with a ship lift worked by means of twenty hydraulic presses, ten on each side, somewhat similar in construction to the lifts now in use at Bombay, Malta, and the Victoria Docks. The powerful hydraulic machinery for these lifts has been supplied by Messrs. Easton & Anderson, Limited, of London and Erith. Fig. 3, on the next page, shows the progress made in the erection of this machinery, all of which is now upon the ground at the Tidnish terminus, within the cofferdam.

(To be continued.)

A NEW METHOD OF TESTING PORTLAND CEMENT.

FEW "new" things are absolutely novel, and most improvements have been foreshadowed ere they have received definite shape. If it be considered necessary to fix the exact date at which a novelty is produced, it is perhaps well to choose the time when it first took tangible form and began to have practical significance, rather than that of its more or less misty inception. On these grounds the method about to be described may be termed "new," but, judged by a more rigorous standard, its claim to novelty might be found invalid.

From time to time experts have striven to improve existing methods of testing hydraulic cements, with more or less success. Both in this country and abroad numerous series of experiments have been carried out with this object, and have sometimes resulted in giving both maker and user better criteria than they possessed before. Owing largely to the tendency of engineers in this country to work each by his own specification, methods of testing are at present very various and often woefully obsolete, and for improvement we must look elsewhere. Since the researches of M. le Chatelier, it is to French engineer-chemists that we must chiefly look for help.

The latest contribution to our knowledge, the author of which may apparently claim to belong equally to both professions, is by M. Deval, Chief Superintendent of Bridges and Roads, and in charge, under M. Salle, of the Public Works Laboratory of the City of Paris, and has been presented to the Société d'Encouragement pour l'Industrie Nationale. That body, having referred it to the Committee of Applied Chemistry, has received a favourable report through M. le Chatelier, acting for the Committee, and the paper has accordingly been published in a recent number of its "Bulletin."

The mechanical tests of Portland and other hydraulic cements generally in use are made cold; the briquettes, after setting and being exposed for a certain term to harden in the air, are immersed in water at the ordinary temperature. The use of *hot* water was originally advocated by Michaelis, and the proposal undoubtedly contained the germ of an important improvement, but was unfortunately discredited by assertions of the existence of a definite relation between the results obtained hot and in the cold.

Objection, that is at first sight not unreasonable, may be taken to this method of testing, on the ground that such a condition as immersion in hot water is almost never encountered by hydraulic cements in actual use, and that in consequence a hot test is superfluous and irrational. But on closer consideration this objection loses force. It must ever be remembered that from the moment a cement is made until it finally ceases to exist as cement it is ceaselessly changing in constitution and properties. Neglecting as adventitious the alteration it undergoes by aëration, either intentional or accidental, its first notable change is that produced by the complex phenomena of hydration, known generically as "setting." This is followed by the slower but generally more important process of "hardening," to which it is difficult to set a term, but which usually ceases to be noticeable after the elapse of one or two years. When fully hardened and exposed—in the work of which it forms part—to natural eroding and disintegrating agencies, it is slowly but inevitably broken up and decomposed until its cementitious existence terminates. It is plain that in ordinary cases the *time* factor is of vast importance, and the inspection and final acceptance or rejection of a batch of cement, if time were the only means of testing available, would have to be relegated to posterity.

Seeing, then, that it is impracticable to secure for experimental purposes one of the main conditions obtaining in actual work, it is futile to try to imitate the rest of those conditions, unless such imitation have advantages of its own. On this broad general ground the objections to tensile tests, when cement is never used in tension, neat tests, when it is never used neat, and hot tests, when it is always subjected to the ordinary temperature of the air, may be met and refuted. The sole object of any test or code of tests is to ascertain what cement will prove reliable when used as a building material and what will not, and, of those cements which are accounted reliable, the order in which they may be ranked. Having thus disposed beforehand of sundry "practical" objections, the method of investigation adopted by M. Deval may be described.

Acting in accordance with the principles enunciated above, he was content to adopt the conventional processes generally used; the briquettes were 5 sq. cm. in section, the tests being made in tension. The mixture used consisted of one part by weight of cement to three of normal sand, and was gauged with the minimum quantity of water necessary. After being made, the briquettes were allowed to harden for a period ranging from twenty-four hours for Portland cements to thirty days in the case of certain hydraulic limes, which were very slow in setting and hardening, owing to the alteration of one of the conditions prescribed above—namely, the use of as little water as possible. At the end of the period of setting the briquettes were immersed in water at 80° C., and remained therein for two or seven days. Parallel tests were made in the cold, the period of immersion being seven or twenty-eight days, these times being found to give results comparable with those of the hot tests at two and seven days. The briquettes were then broken in the ordinary way. On carrying out a series of such tests with six samples of Portland cement as representative as possible of the typical differences in quality that are encountered, the following conclusions were arrived at:—

1. Cold tests are fallacious, inasmuch as they may fail to detect, or may even hall-mark as good, thoroughly bad cements.

2. Portland cement of good quality, gauged in the manner described above, will resist the action of water at 80° C., attaining, moreover, in seven days, about the same tensile strength as is reached in the cold after twenty-eight days.

3. Where for any reason, such as the presence of much inert matter—as may be the case with a poor cement—setting has not been completed before immersion, disintegration will occur, even though the cement be sound. A longer period for setting must then be allowed.

4. The presence of *free lime* in appreciable quantity is detected by the hot test, the tensile strength being lower than that given by the cold test at twenty-eight days, and the briquettes cracking, swelling, or disintegrating in a highly significant manner. In cases where the percentage of free lime is small, the cement will withstand the action of water at 80° C. if the period of setting be extended, but will have a lower tensile strength at two and seven days than when tested cold at the corresponding times—viz., seven and twenty-eight days.

This last result is the most important contribution to our means of judging of the quality of Portland cement that has been made for years. Attempts have been repeatedly made to devise chemical methods for the detection and determination of free lime in Portland cement, but without success. A very obvious plan, and one still practised at times with refreshing simplicity, consists in treating a weighed portion of the cement with water or a solution of sugar in order to "dissolve out the free lime." The free lime is certainly dissolved out, but with it goes into solution the lime combined to form the silicates and aluminates which constitute hydraulic cement. Analyses professing to give the percentage of free lime, and stating it as 25 per cent., are not of extreme rarity, and have no other claim to be considered valuable.

Data have been accumulated concerning fifteen other samples of Portland cement, both the "natural" variety from cement stone, and that made in the ordinary manner from chalk and clay. During these experiments a further advantage was shown to result from the use of the hot test, inasmuch as the acid silicates that play the part of puzzolanas in certain highly silicious

THE CHIGNECTO SHIP RAILWAY.

(*For description see page* 97.)

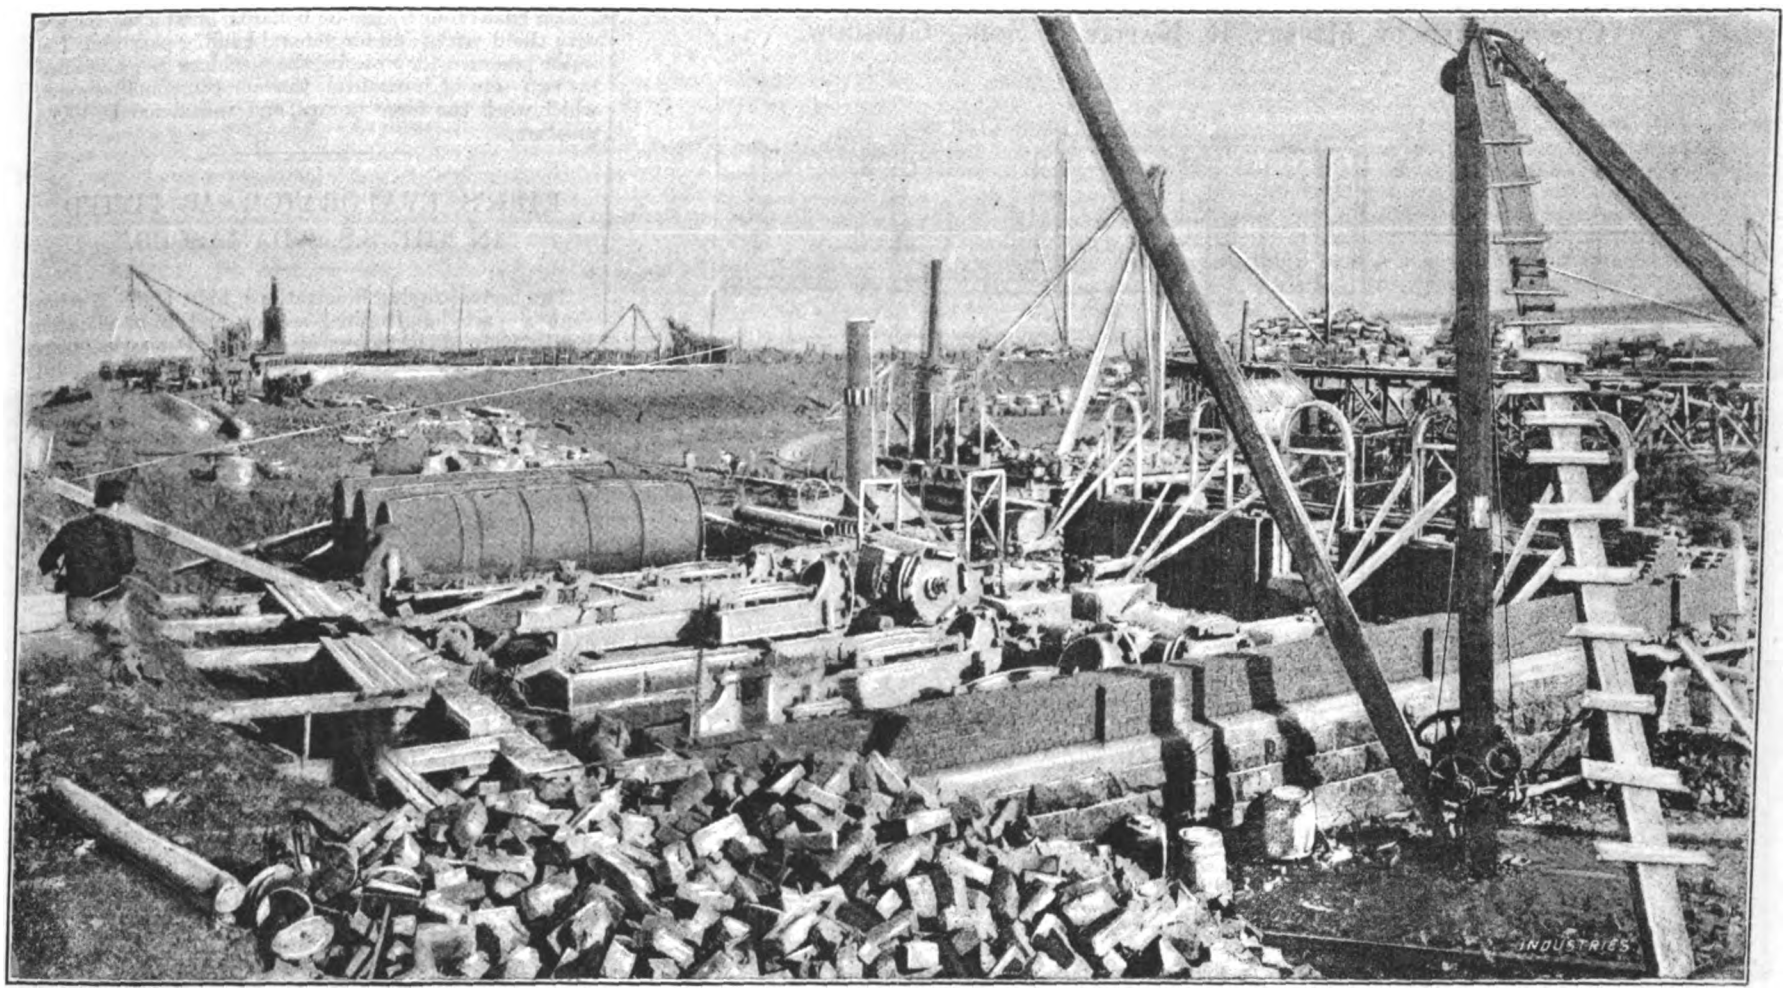

FIG. 3.—ERECTION OF THE HYDRAULIC PLANT FOR WORKING THE LIFTING DOCK.

cements have their hardening hastened by the high temperature, and raise the tensile strength, causing the cement to assume its proper rank in the scale of quality—a result impossible with the ordinary cold tests on account of the slowness with which such silicates react at a low temperature. Similar proofs of the general utility of the hot test were obtained in the case of slag cement, which has now become a considerable article of commerce and a factor that must be reckoned with both by maker and user. Experiments were also carried out with certain special quick-setting cements, and with a good variety of hydraulic limes, with the same main result.

Certain weighty conclusions which M. Deval appends to his paper demand careful consideration. Admitting the value and wide applicability of the hot test, it is obvious that its greatest utility will appear in the case of "natural" cements, the composition of which is less directly under control than is that of Portland cement. The reason for this is that such cements are made by burning the raw material (argillaceous limestone) without attempting to render it homogeneous. Thus, though analysis may show that the raw material, taken in mass, has the composition necessary for the production of good cement, a given lump may contain altogether wrong proportions. As no actual fusion takes place in burning cement, the evils of imperfect mixture cannot be remedied in the kiln, and one and the same piece of clinker may be on one side composed of overlimed, and on the other of overclayed, cement. Considering the periodical spasms of activity in the exploitation of "natural" cement, one of which is only just waning, a method capable of detecting its chief weakness cannot but be useful. Portland cement offends less frequently in this way, but the irrational demand for a cement of very high tensile strength sometimes leads to it being overlimed, and disastrous effects may result.

With regard to the adoption of the hot test as a supplement to or substitute for those with which we are familiar, it may be safely predicted that manufacturers will be vigorously opposed to it, as it discriminates too nicely between fairly good cements and those of really high quality. The prejudices born of inherent conservatism will delay its use by some consumers, but a slowly wakening regard for their own interests will finally lead to their conversion. The erroneous belief of Michaelis, already referred to, that a definite relation exists between the results of hot and cold tests, will doubtless have a retarding effect. To diminish that effect a consideration of the following statement should suffice:—The whole merit of the hot test consists in the divergencies of the results obtained by it from those given by the cold test; where the latter leaves a bad sample undetected, or only throws intangible suspicion upon it, the former condemns it without fail, the discrepancy being a measure of its success.

No sweeping change in our mode of testing is possible, or even desirable. More data—above all things those comprising the comparison of laboratory tests with the behaviour of the stuff in the work—must be collected, and to that end it is of urgent necessity that every engineer already having his cement habitually tested should include the hot test among the methods used.

HYDRAULIC HOISTING PLANT FOR H.M.S. "VULCAN."

THERE have been recently carried out on board the new torpedo depôt ship "Vulcan," at Portsmouth, a series of trials of hydraulic boat-hoisting machinery, supplied by Sir W. G. Armstrong & Co., of Elswick, which have attracted some interest in consequence of the novelty of the fittings introduced for the first time in a ship. Chief among these is a pair of enormous "goose-neck" cranes, placed one on each side of the deck, almost amidships. These cranes are, in fact, huge davits, whose total height is 65ft., with an overhang of 38ft. It will be readily understood that a bent beam of these dimensions, and weighing about 27 tons, requires special arrangements for its support and security. To provide these about 30ft. of the total height lies buried in the hold, passing down through the upper, main, and protective decks to the bottom of the ship, where the foot rests upon a special steel casting bolted to the structure of the vessel. In the upper deck is secured a heavy steel socket, in which the crane rotates. The beams themselves are built of steel plates and angles on the box-girder principle, but specially strengthened and stiffened. By this method of construction the lifting machinery is permitted to be erected within the pillar of the crane, well down in the hold, and consequently protected from gunfire, while the portion above the protective deck is screened by an armoured tube. The lifting machinery consists mainly of two cylinders, 17½in. and 5½in. diameter, fitted with rams, which have a vertical travel or stroke of 10ft. The small cylinder plays a very important part in the working of the mechanism. Both rams are rigidly attached at their upper ends to a huge cross-head, which carries four sheaves on a pin at right angles to the axis of the cylinder. At the lower end of the cylinders are four sheaves, corresponding in a vertical plane with those above, the whole thus forming a system of pulleys. The thrust exerted on the cross-heads by the rams at the ordinary working pressure of 1,000lb. per square inch is about 118 tons, one-fourth of which only is available for lifting purposes, owing to the multiplying power of the pulleys, which increases the 10ft. stroke to a lift of 40ft. The ropes, 5½in. in circumference, are of steel wire. The most interesting feature in the mechanism is the attachment of the small cylinder already mentioned, the special duty of which is to hold and keep taut the slings after they have been hooked on until a favourable moment for hoisting the boat presents itself. This is of the utmost importance in a seaway as a preventive against accidents. The arrangement of valves is such that the main lifting power cannot be applied until the small cylinder has been brought into action. It also provides for the escape of the water when the ram is driven back by the falling of the boat. The turning motion of the cranes is effected by means of two cylinders fitted with rams 16in. in diameter, and having a direct thrusting force of 90 tons. These are placed vertically alongside the pillar of the crane, and the rotatory motion is given by admitting the pressure to one or other of the

KIRK'S EVAPORATOR FOR MARINE BOILERS.

CONSTRUCTED BY MESSRS. R. NAPIER & SONS, GLASGOW.

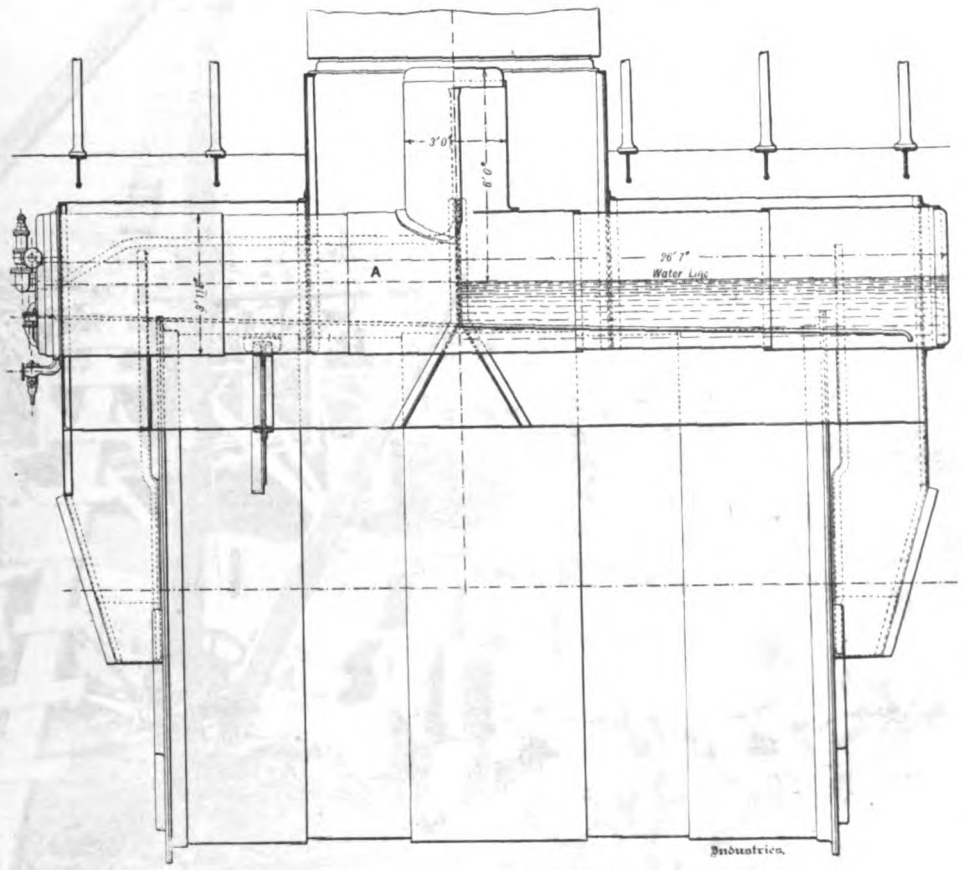

FIG. 1.—PART LONGITUDINAL SECTION OF BOILERS AND EVAPORATOR.

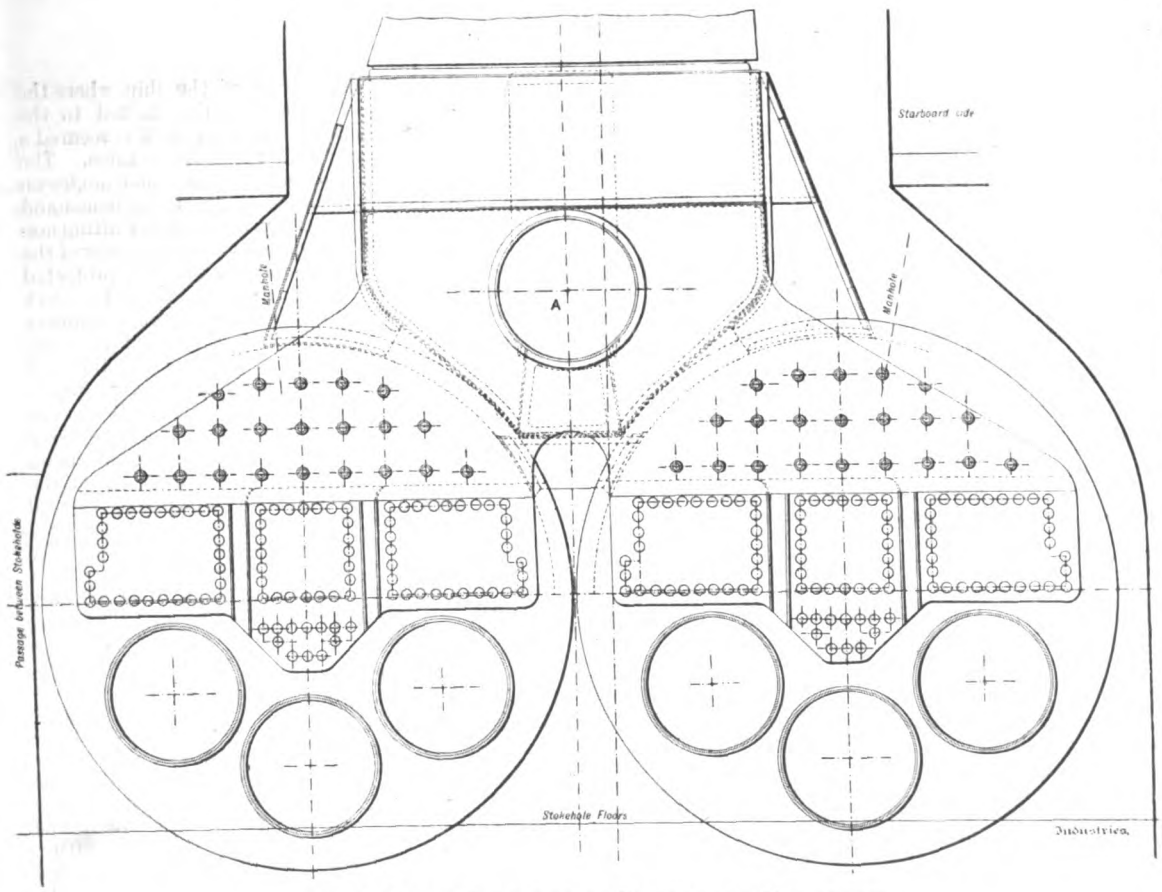

FIG. 2.—FRONT ELEVATION OF BOILERS AND EVAPORATOR.

presses. The cranes have a turning range of 250 deg., which will enable a boat to be picked up from alongside the ship and deposited in almost any position on deck. It is, however, obvious that, since the "Vulcan" is 58ft. wide and the cranes are 40ft. apart, it would be impossible, without special devices, to lift a boat remotely situated from the part where the crane is fixed. In order, therefore, to provide for the contingency of one of the cranes becoming disabled in action or by accident, the torpedo boats (of which the ship carries six) are stowed in crutches fitted on trolleys actuated by worm gearing and moving upon rails, by which means they can be conveyed from one side of the ship to the other. The cranes have been tested, and every part of the machinery successfully withstood the tests.

The service derrick attached to the mainmast for boat-hoisting purposes has also been fitted with hydraulic machinery. In addition to the cranes and derricks, there are on board four hydraulic bollards, or winches, for use with the derricks and for general hauling purposes. The water pressure for working the machines is maintained by two sets of horizontal tandem compound engines, which work the force pumps, and use steam at 100lb. pressure.

KIRK'S EVAPORATOR AS FITTED IN THE S.S. "DAMASCUS."

THE accompanying illustrations, Figs. 1 and 2, represent a part longitudinal section and front elevation respectively of the boilers of the s.s. "Damascus," fitted with Dr. Kirk's evaporator. In Figs. 3 and 4, on page 101, we further give end and side elevations respectively of the portion of the evaporator which projects through the boiler front, showing the valves employed. The evaporator A is of the simplest construction, and consists of a plain low-pressure egg-ended boiler placed in the uptake between the two main boilers, and of sufficient size to allow a man to get into it for cleaning or for repairing purposes. It is fed from the sea and blown off in the same way as an ordinary boiler, the feed being supplied by any of the pumps supplied with water from the sea, or by a special pump. Practically it is found most convenient to work with a continuous feed and a continuous blow off, although from the quantity of water contained in the evaporator the blowing off may be done intermittently if preferred.

The evaporator was originally worked under a vacuum, the steam pipe from it being connected to the condenser, but it was found that under these conditions priming took place so readily as to be somewhat troublesome.

The best working condition is under a pressure of 10lb. to 20lb. above the atmosphere. This may be attained by allowing the steam to escape through a safety valve on its way to the condenser, or, better still, by connecting it to the low-pressure cylinder casing, with an alternative escape through a safety valve, as above described. The advantages claimed for this special evaporator are (1) its simplicity of construction, and consequent ease of cleaning; (2) the evaporation of salt water at a much lower temperature than the evaporation in the main boilers, consequently the heat that would be with difficulty utilised in the main boilers is efficacious in the evaporator. It has also been found that even when by accident the feed or blow-off has been omitted the heat of the uptake is not sufficient to injure the riveting. The evaporator, which is being introduced by Messrs. R. Napier & Sons, Glasgow, has, we are informed, proved adequate to keep the boilers of the "Damascus" fully supplied with fresh water. After a run of forty days the scale formed in the evaporator was found to be only about one-eighth of an inch in thickness, and was easily removed.

MINING IN SPAIN.

LEAD mining and smelting in the Garrucha district of Spain, we learn from a Foreign Office report, is on the decline, owing to the continued stoppage of the general pumping station on the mines. Steps have, however, been taken towards remedying this state of affairs.

The principal iron ore mines of the district are situated in the Sierra of Bedar, and have recently been greatly developed. The Sierra, where the deposit occurs, may be broadly defined as consisting of very old schists capped by limestone. These schists are, as far as can be learned at present, absolutely azoic, not a single trace of organic remains having yet been found, but, judging from their lithological character, they may be described as of lower Silurian or Cambrian age. They are overlaid by a thick-bedded yellow crystalline limestone. The occurrence in this of fossil remains, together with the presence of magnesia, points to these limestones being of Permian age. The leading lode is probably a contact lode between the schists and the dolomites. The secondary lodes are sometimes parallel, and sometimes at varying angles and dips to it, and pass both into the schists and limestones. The slopes of the Sierra are covered in places by Tertiary limestones and conglomerates, but the lodes never pass into these, and are, without exception, confined to the paleozic rocks.

In one of the mining setts near the village of Bedar there are as many as twelve workable lodes, the principal one being upwards of 100ft. wide, and extending for a

Digitized by Google

considerable distance across country. In another sett, near the village of Serena, about two miles to the westward, the great lode has been followed down to a depth of over 100ft., without showing any indication of narrowing or of the ore giving out, whilst in the properties adjoining the lodes have been worked to a depth of upwards of 120ft., with a result that, although on the surface the size of the lode may be small, in depth it is found to widen out very much. In one case a narrow surface lode widened out to 45ft. below. The ore is worked both in open cast and in high galleries. It is let down an incline to a wire rope tramway station, whence it is conveyed to Garrucha at the rate of about 45 tons per hour, at a cost of about 3s. 2¾d. per ton, including repayment of cost of tramway and delivery from stock to steamer. The production is naturally governed by the quantity which can be transported by the tramway. It is now about 120,000 tons per annum, but it could be greatly increased if a more suitable means of transit were provided. The ore is black and brown hematite, and contains from 55 to 62 per cent. of metallic iron, and its freedom from sulphur and injurious quantities of phosphorus, low percentage of silica (in some cases under 1 per cent.), together with the presence of a considerable quantity of lime, makes it highly suitable for steel making purposes. Its physical condition varies considerably, and it is curious to note that the ore in the eastern group around Bedar is hard and lumpy, while that in the mines to the westward is soft and purple, and consists of only about one-tenth in lumps.

The great desideratum for this magnificent deposit is a railway connecting it with the coast. The present means of transport is altogether inadequate to the importance of the mines, many of the best of which are unworked for the want of means of communication. A good broad-gauge line would not cost more than £60,000, and would pay for itself in a couple of years if worked in combination with the mines. The supply of really good ore is no doubt very great, and there is little doubt that this line would have been constructed had the late high prices of iron continued. The sudden fall appears to have checked the influx of capital into the iron industries, although in this case it would appear to be sound policy to build the means of transport whilst prices are low and material cheap.

THE ENGINEERING SCHOOL, CORNELL UNIVERSITY.

It has been said that the great ambition of a rich Briton is to found a family, while that of a rich American is to found a college. No doubt there are exceptions to both those statements, but it must be admitted that there is a considerable amount of truth in them. The latter especially has had many exemplifications during recent years, and colleges and universities are being instituted and endowed in America at a rate which is apt to raise the envy of educationists in this country. We need not attempt an enumeration of them, but will confine our attention to one which is destined to take a high position in the advancement, not only of the higher learning, but also of technical education. We refer to Cornell University, which seems in many respects to be the ideal of a modern university, combining as it does an education in the learning of the past with the knowledge rendered necessary by our present state of civilisation. We believe that it is in the happy, or unhappy, position (according to the point of view from which the matter is considered) of being as rich as it can possibly be—that is to say, it now holds property and investments to the utmost amount allowed by its charter. Whether such a state of affairs can be amended or not we cannot say, but it must be admitted that it is a very peculiar position for any institution to occupy. During the past year alone it received for general purposes about one million dollars, a share of which will, of course, be spent on the engineering department. We understand that not less than $200,000 have been spent on apparatus and material in the engineering department and accessories alone, a great part of which is employed in instruction and research in Sibley College. This college, which forms an essential part of the University, was founded by Hiram Sibley, an old friend and comrade of Ezra Cornell, the founder of the University, and is devoted to the mechanical arts and to mechanical engineering. In one of our early volumes (see *Industries*, Vol. I., page 566), we described its general arrangements, and we shall now only notice a few of its recent developments.

What is of more importance even than its endowments, Sibley College has been fortunate enough to secure the services of a first-class man as its director, and of an efficient staff of teachers, for in education money is not the only, nor, indeed, the main thing. Unless an institution is managed in the proper spirit, and by men who are able to keep it up to the demands of the times, its teaching may degenerate into a mere matter of official routine, however excellent its buildings and equipments may be for their purpose. The director of Sibley College is Professor R. H. Thurston, whose name is as well known in this country as in America, and who, by his energy and ability, has done so much to make the College what it is. Professor Thurston was for many years connected with the Stevens Institute, and his experience there and his early training well fitted him for the position which he now holds. His papers and articles on subjects involving not only theoretical considerations, but also a large amount of experimental work, testify not only to his unwearied activity, but also to his great ability and the extent of his knowledge. He is seconded in all his efforts by a most able staff of teachers, and we have no doubt that, with all his advantages, Professor Thurston will be able to make Sibley College one of the most complete engineering colleges in the world.

What may be called the general and preparatory subjects, such as languages and the pure sciences, are taught to the students of engineering in the University proper, so that the whole resources of Sibley College can thus be devoted to the applications to engineering and to experimental work. The main department of the College is, of course, that devoted to mechanical engineering. This is subdivided into the sections of electrical, steam, marine engineering and naval architecture, and chemical engineering, all of which have their basis in a good knowledge of mechanics, both theoretical and practical. Each of these subjects is fully represented by a course of theoretical instruction and of laboratory work, for it has been fully recognised that the latter is most essential in the training of engineers, and that, in fact, the lecture-room, the drawing-office, and the laboratory are only departments of the same class. While there is no pretence of training apprentices, still there are opportunities for the students to become skilful with the tools of all the trades subsidiary to engineering, and by the time they leave college they are thus well equipped to begin a course of practical experience in some department of engineering. It must be admitted that in America formal apprenticeships have almost disappeared, and young men after leaving school or college generally enter works as improvers, and pick up experience as best they can.

Although the workshops and laboratories at Sibley College are already very extensive, we believe that during the present year they will be nearly doubled. New chemical and physical laboratories are to be supplied, and additional opportunities are to be given to the increasing number of those who intend to pursue semi-professional in conjunction with their professional studies, and to study advanced mathematics, political economy, and patent law.

The usual course of instruction extends over four years, and includes a systematic curriculum in mathematics (pure and applied), in physics and chemistry, and in their application to the different departments of engineering. General culture is not forgotten, special attention being paid to modern languages, history, and political economy. The first two years are taken up with what may be called the more general subjects, the third with those of the department selected by the students, while in the fourth they specialise still further by selecting the section belonging to their special calling. This seems a very good arrangement, as it first lays a broad basis of education, and then proceeds to give the students a useful introduction to the main work of their lives.

The College is now being largely used by graduates of other colleges who come up to take advantage of the opportunities for experimental research and to fit themselves for advanced degrees. Many of these intend to pursue the vocation of instructors in science and in technical schools. Indeed, we believe that many professors of engineering go to Cornell and Sibley College to get experience in laboratory work, and to make scientific and engineering researches such as their earlier opportunities failed to offer them.

A great movement in this country for the improvement of engineering education and of technical education generally is now being made. Our object in writing of Sibley College is to direct the attention of educationists to a well-organised experiment now being made in America, which is well worthy of their careful study.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 27th January, 1891.

Iron.—Business in the iron market is still very inactive. It may be hoped that a change for the better will make itself felt with the resumption of the building and other industries which have been interrupted for the last two months by the exceptionally severe weather. There are some heavy contracts to be given out, amongst others one for the furnishing of cast-iron pipes for the extension of the water supply of Paris at an estimated cost of about 1,500,000fr. The P. L. M. Railway Company are on the point of soliciting tenders for the delivery of 20,000 tons of steel rails, but this has not yet influenced the market, and no improvement has taken place in prices. A like report reaches us from the provinces, where the amount of business done is very limited, and the prices officially quoted much higher than those obtained. At the last meeting of the Paris Syndicate the following prices were established:—First-class bars, 128s. 6d., and joists, 136s. 6d. per ton. The improvement in the English market and the steadiness in the price of coal here will doubtless contribute to a speedy rise in quotations.

The Coal Market.—The coal market continues to be very firm. This is to be accounted for partly by the continuous growth of industries in general—with the exception of the production of metals, which has not increased in France of late years—and partly by the augmented domestic consumption during the winter months.

Copper, Lead, Tin.—The copper market is slightly firmer than it was last week. Best Chilian bars command £57 10s. to £58 the ton. The prices for tin remain unchanged, with the exception of Billiton, which has fallen 9s. per ton. Lead has gone up slightly, ordinary marks being quoted at £13 5s. the ton.

Importation of Iron Ore into France.—During the first eleven months of 1890 1,419,400 tons of iron ore were imported, showing an increase on the first eleven months of the preceding year of 174,000 tons. Of this total Germany supplied 886,526; Spain, 441,320; Belgium, 34,178; Algeria, 41,070; Italy, 10,969; and other countries, 5,437 tons.

Hardening Tubes for Guns.—An interesting experiment in hardening these tubes on a large scale took place recently at Rive-de-Gier. The piece to be operated on was a tube for a 34-centimetre gun 54ft. long, and weighing nearly 26 tons. The experiment proved a general success, and there is a probability of even better results being arrived at, but we think this is the most important operation of the kind that has been hitherto successfully carried out.

BERLIN, 26th January, 1891.

Electrical Transmission of Power at Königsbronn.—An installation for the transmission of power for the use of the Government foundries at Königsbronn, in Wurtemberg, has recently been opened. The supply of power is obtained by means of a turbine from a stream at that place, and the dynamo and the turbine each make 600 revolutions in a minute. By means of a conductor, which is carried over the roofs of the houses across the railway to the opposite side of the valley, 40 horse-power is transmitted for the working of twenty-five powerful lathes, which are employed in the turning and polishing of shafts for the Königsbronn foundries, and had been previously driven by steam power. The installation was carried out by the Esslingen Machine Works, and the turbine was erected by the machine works of Herr J. M. Voith, of Heidenheim. By means of an automatic regulator, invented by Herr Pfarr, of these works, the power transmitted is independent of the varying conditions of the stream. Other installations may be expected to follow this, which is the first erected in Wurtemberg.

International Electrical Exhibition at Frankfort.—A conference between representatives of the Berlin General Electricity Company, the Oërlikon Machine Works, and the Lauffen Portland Cement Works, with reference to the Frankfort Exhibition of 1891, was recently held at Munich. An agreement was entered upon as to the apportionment of the expenses of the electrical transmission of 300 horse-power from Lauffen to Frankfort, in view of the fact that previous trials at Oërlikon had shown that the undertaking would probably meet with success. The carrying out of this interesting undertaking depends on the Exhibition Committee obtaining the loan of the necessary conducting poles from the Postal Administration and the Wurtemberg Telegraph authorities. The question is now continually arising as to the use of streets and roads for the transmission of electric light from a distance, and it may be hoped that the authorities will afford facilities for the carrying out of such an important work as the present.

Industrial Berlin.—There are in Berlin 1,627 fixed steam boilers and 1,353 fixed steam engines, indicating 45,821 horse-power. In addition there are 285 portable boilers and engines indicating 2,229 horse-power, making a total of 48,050 horse-power. A comparison between the present state of industry and that of 1879 shows to what a large extent the industries of Berlin have been developed during that period. In 1879 there were in Berlin only 1,211 boilers and 983 steam engines, indicating 20,286 horse-power, thus showing an increase on the ten years of no less than 27,764 horse-power.

VIENNA, 26th January, 1891.

The Iron Market.—There is no important change in the Austrian iron market. The trade in bar iron and boiler plates shows no increase, but the tendency is firmer, and with better weather an amelioration of the situation may be expected. An important order for thirty-four passenger carriages has been given by the Northern Railway Company. The prospect for the year is good, and the enlargement of the city will probably lead to increased building operations.

The Coal Market.—During the past week the coal market has continued active. The demand both for home and export purposes is very brisk, and railways have some difficulty in coping with the traffic. There is a need of more rolling stock, especially in the Bohemian district. Bohemian brown coals found a sale in this market when Silesian coal could not be forwarded by rail owing to the recent snowstorms. Representatives of works situated on the Dux-Bodenbach Railway have been sent to Dresden to obtain more waggons from the State Railways of Saxony, as the greater part of the coal produced is forwarded by these lines. From the 7th to the 10th inst. the export to Saxony amounted to 84,000 tons, against 79,000 tons in the same period last year. The total transport on the Dux-Bodenbach Railway in the second week of this month amounted to 47,000 tons, and that on the Prague-Dux line to 31,000 tons.

Electrical Engineering.—The central station of the Vienna Electricity Company, in the Kaunitz Street, will shortly receive an important extension. The installation for the electrical lighting of Sophia, in Bulgaria, was taken over by Messrs. B. Egger & Co., of Vienna. During this week the Vienna Town Council has been deliberating on the concession granted to the International Compressed Air and Electricity Company (Popp), and the proposals of the company have been adopted, with small and unimportant alterations. The building of the central station for the supply of compressed air will soon be commenced. The question of an electrical railway in Vienna has been again brought forward through the enlargement of the city. Last week Herr Hochenegg read a paper on electrical traction at a meeting of the Electrical Association. On the conclusion of the paper, the Association passed a resolution that suitable measures should be taken to ascertain the best mode of employing electricity in Greater Vienna. This resolution seems to point to the construction of an electrical railway at an early date.

Bohemian Exports to America and the McKinley Act.—Bohemian exports have suffered no damage from the effects of the McKinley Act, but, on the contrary, the exports to the United States during the last quarter of 1890 show an increase, the total exports from Bohemia during this period amounting to $2,500,000, as against $800,000 in the corresponding period of the previous year. The export of raw sugar has the largest share in this increase. The export of porcelain and earthenware was increased by $40,000, beer by $10,000, cloth and woollen goods by $12,000, and linen and cotton goods by $20,000. The exports of certain raw materials have also shown a large increase, which is a sign that the McKinley Act has not produced the ill effects which were feared.

DÜSSELDORF, 27th January, 1891.

Iron Market.—The iron market is quiet, and there has been no great alteration since last week.

Coal Market.—In consequence of difficulties in transport the price of coals is rising. Many manufacturers have paid for a waggon of 10 tons from 180 to 200 marks, which might recently have been bought at from 90 to 100 marks. On the 23rd inst. there occurred at the Hibernia pit, near Gelsenkircher, an explosion of fire-damp, by which 41 men were killed and 24 men injured.

Transportation Difficulties.—The heavy falls of snow continue to cause serious inconvenience to traffic in all parts of the German Empire. The Upper Silesian and the Ruhr districts suffer most largely. In the latter the number of delayed waggons becomes greater from day to day. The Rhine is frozen from Emmerich to Düsseldorf, and from the Loreley upwards to Mainz, and the thickness of the ice is in some places more than 20ft. In consequence of the recent thaw it is feared that the banks of the Rhine will suffer extensive inundations from the drifting of ice. Similar difficulties exist on the Weser and Elbe, and the harbours of Bremen and Hamburg suffer much. The transatlantic steamer "Augusta Victoria" left Cuxhaven on the 23rd inst. for Southampton.

General Engineering.—The makers of engineering work of almost every description have fairly bright prospects. Makers of locomotive engines have got large orders and expect to receive others shortly. The German mining industries are now placing plenty of orders for hauling and pumping engines. Besides this some firms have got good orders from foreign houses. Amongst these are two sugar mills which are to be erected near San Francisco in California by Messrs. Langer and Kundhauser, of Grevenbroich. The Halle'sche Maschinenfabrik u. Eisengiesserei in Halle is busily engaged in finishing a series of sugar mills for Java. Messrs. Siemens & Halske, of Berlin, have recently received an order from the town of Stockholm to erect there a central electrical station for the supply of 15,000 glow lamps.

German Pig Iron Production.—According to the statistical records compiled by Dr. Rentzsch, the German pig iron production in the year 1890, excluding charcoal and scrap iron, was in tons of 1,000 kilogs. each:—

Forge pig and spiegel	2,029,139
Bessemer	438,527
Thomas	1,555,693
Foundry	539,666
Total	4,563,025

The total production in 1889 was 4,387,504 tons. The monthly production was in

Electric Transmission of Power.—An interesting installation has been put up at a saw mill at Neuss by the Deutsche Elektricitätswerke, of Aix-la-Chapelle. The motor employed is one of 20 horse-power, which serves to haul logs of wood up to the works from the neighbouring Erft Canal. The dynamo supplying current to the motor is also used for lighting the premises.

AMSTERDAM, 26th January, 1891.

The Weather and Navigation.—The change in the weather has brought a welcome revolution in the means of communication, although the effect of the thaw upon the frozen rivers is as yet slight. The snow has almost disappeared, and with it one of the chief hindrances to regular railway traffic. The goods train service with Belgium and Germany has at last been partly resumed.

Report upon the State of Navigation.—At Rotterdam an interesting report has been published, prepared at the request of Mr. J. de Kuyper, the Dutch Consul-General at Antwerp, by Mr. J. W. Welcker, State Civil Engineer, employed upon the new waterway. He had to solve the important problem how it comes that Antwerp has been a closed port, whilst Rotterdam was, and is, available for all ocean steamers, despite the late severe frost. Mr. Welcker's report tends to show that the action of the Maas helps to keep the port of Rotterdam free from ice, by means of a strong current, which takes the floating ice away to sea. At Antwerp the tidal movement of the sea causes a contrary effect. It forces the ice back, and this consequently blocks the approaches of the port, and the Scheldt itself, where it soon solidifies into a compact mass forming an impenetrable barrier to all ships.

The Dutch South African Railway Company.—The management of this undertaking has decided to stop all work upon the lines during the season in which pestilential fevers cause great mortality among the staff of workers. But the building of the railway bridge over the Komati River near the Portuguese frontier will be pushed on as much as possible, and the operations upon the first section likewise.

Dutch Artisans in London.—The Dutch Consul in London has issued a warning against Dutch artisans going over to the great Metropolis in search of work. He points to the already overstocked labour market, and opines that there is no chance whatever for foreign workers to earn a living there under present circumstances.

International Association of Customs Tariffs.—The Dutch Government has submitted a Bill to the approval of the States-General for a vote of 1,600fr. towards the cost of instituting an International Board of Fiscal Statistics, to be established at Brussels, and 4,100fr. a year thereafter towards the expense of maintenance. The idea of forming this Board originated with Belgium. The Belgian Government summoned a conference, which met last July at Brussels—forty-one States participating—and decided to found the Bureau, whose function consists in collecting international statistics bearing upon trade, industry, and finance, but principally customs, to be translated into the various languages of the States participating, for distribution. The primary cost of establishment is computed at 50,000fr., whilst 125,000fr. a year will be required for maintenance.

An International Agricultural Congress.—In the coming month of September the unusual spectacle will be witnessed at the Hague of an International Exhibition organised by a foreign Government in a country not its own. The French Government will organise and open there an International Agricultural Exhibition, the idea of which originated in 1889 during the Agricultural Conferences at the Paris Universal Exhibition. Naturally enough, the French Government has sought the support of the Dutch Government, and the latter has already cordially promised to lend it.

STOCKHOLM, 24th January, 1891.

The Stockholm General Telephone Company.—This company has offered to members of Parliament to instal telephones in their private residences on payment

Digitized by Google

of 30kr. for the whole of the session. Telephonic communication is extensively used by the general public in Stockholm.

THE SWEDISH NORWEGIAN RAILWAY COMPANY.—The fate of this concern will probably soon be decided, as Mr. L. Annerstedt has gone to London as the representative of the Swedish Government in order to negotiate with the vendors. The debenture-holders must look upon an arrangement with the Swedish Government as their last chance, although the sum of about £400,000, which the Swedish Government is prepared to pay, is a very small percentage of the millions sunk in this undertaking.

TENDERS FOR COAL AND COKE.—The Swedish State Railways are inviting tenders for the supply of a large quantity of coal and coke. Of locomotive coals 21,000 tons are required at Stockholm, 20,000 tons at Gothenburg, 30,000 tons at Malmö, 10,000 tons at Stugsund, 13,000 at Sundsvall, and 3,500 tons at Trondhjelm.

PROJECTED RAILWAY.—Another outlet from the North Trunk Railway to the sea is under contemplation, the Hernosand-Solleftea Railway Company having applied for a Government loan of 2,350,000kr., which is half the calculated cost of the projected line. There is every prospect of the loan being granted.

UTILISATION OF WATER POWER.—Electricity is likely to prove a great boon in the utilisation of the large amount of water power which Sweden possesses in its numerous and large waterfalls. One of the largest schemes of this kind is that in connection with the Elfkarsby Fall, in which several prominent engineers and capitalists are said to be interested. It is a question of the transmission of power by electricity on a large scale.

THE MUNKSUND SAW MILLS.—The saw mills at Pitea and the Bergfors Estate have been sold to Mr. P. Wikström, of Stockholm. This valuable property has been in the hands of Englishmen since 1867, and the opinion with regard to this sale seems to be that it seals the fate of the "Gellivara Aktiebolag," as its remaining property entails a less and will probably soon have to be sold. This part of the property may, however, become valuable when the iron industry in those parts is a little more advanced.

CHRISTIANIA, 24TH JANUARY, 1891.

THE UNION PAPER MILLS COMPANY.—This company, which possesses the largest paper mills in Norway, has now bought the southern half of the Skotfos waterfall, at a price of 70,000kr. The Union Company is thus owner of the whole of Skotfos, and has at its disposal water power of about 8,000 horse-power. The Skotfos is one of the largest waterfalls in Norway which has been turned to industrial account.

THE ICE EXPORT.—The export of ice from Norway shows a steady and continuous increase, and the figures for last year head the list. Up to the end of November the export amounted to over 308,000 tons, and the total export for the year probably amounts to 316,000 reg. tons. The figures for the previous four years are 254,000 tons in 1886; 266,000 tons in 1887; 244,000 tons in 1888; and 290,000 tons in 1889. The financial result of last year's ice export is satisfactory, although it varies very much for the different shippers. Those who sold early did far better than those who held back. The encouraging reports from America in the spring buoyed up the market, but the rise was only temporary. In October and November ice was sold at one-fifth of the price which had been refused in May. Owing to the present severe winter the prospects are not of the brightest. Last year's exports to America from Norway amounted to about 16,000 tons.

FOG HORNS.—Mr. O. C. Hausen's manufactory of fog horns at Skadesnäshaven has made nearly 7,000 fog horns during the last ten years. Mr. Hausen has supplied fog horns to the Norwegian, Swedish, Danish, Dutch, German, and United States navies, and to the lighthouse services of Norway, Sweden, Denmark, and France. The Spanish navy has quite recently sent an order. The works, which were started on a small scale, have been constantly increasing.

THE "DEIMEL" LIGHT COMPANY, LIMITED.—Mr. J. Werner has been appointed agent for the "Deimel" lamp in this city.

COPENHAGEN, 24TH JANUARY, 1891.

TRAMWAYS.—The Copenhagen tramways have proved first-rate investments, and none more so than the Nörrebro Tramway Company, of which the balance-sheet for last year shows receipts amounting to 326,970kr., and expenses to 224,605kr., leaving a net profit of 102,364kr. The Board get 12,098kr., the sinking fund 2½ per cent., the reserve fund 6 per cent., the sick and pension fund 3 per cent., the heirs of the builder 1 per cent., and the shareholders a dividend of 16 per cent.

PROJECTED NEW RAILWAYS.—Several new railways are projected in Denmark, both Government and private lines. One plan comprises a Tange-Silkeborg railway, in connection with a Lunderskov and a Veile-Brumminge railway, which lines are expected to prove of great importance, as regards both the local traffic and the communication with Germany and England. The promoters hope that these lines will be built as State railways.

ICE-BREAKING STEAMERS.—The capital service rendered by efficient ice-breaking steamers has been amply illustrated during the last few weeks' frost. They are almost daily at work, both in the Copenhagen harbour, and occasionally used right across the Sound, in the Great Belt, in order to keep up the important connection between Korsör and Nyborg, and in the Little Belt. It is only during the last few years that the immense practical value of ice-breakers has been realised, but now they are being generally adopted.

MARSTRAND BREWERIES.—These breweries, which have stood in the way of an amalgamation of the Copenhagen breweries, have issued their balance-sheet for the year ending 31st October, 1890. The result is by no means satisfactory. The gross profits amount to 143,997kr., but the net profits show a deficiency on the year's working of 14,975kr. The share capital is 1,800,000kr., and there are debentures for 867,069kr. It is difficult to understand why this large capital has not been able to yield any profit to the shareholders.

THE EFFECT OF FROST UPON RAILS.—The recent severe frost has caused much damage on the Danish railways through the snapping and cracking of the rails. Between Korsör and Copenhagen—a distance of some sixty miles—sixteen rails had given way the other day, the metal being rendered very brittle by the cold.

MADRID, 26TH JANUARY, 1891.

THE TRANSATLANTIC COMPANY.—The annual meeting of the shareholders of this company was held recently. For the past six years no profits have been available for distribution, all the earnings having been spent on the improvement of the fleet. Although the report attempts to show that the business is improving, the balance sheet teaches a different lesson. With a capital of £1,000,000 there is a debt of about £2,500,000, while the assets, which consist chiefly of the value of the ships, are stated to amount to £2,400,000. This state of affairs is not reassuring to the shareholders. Though some few of the ships are new and well constructed, many others are slow and old-fashioned. If the company were to liquidate, it is possible that the whole of the capital would be lost.

LAUNCH OF A STEAMER AT CADIZ.—The first merchant steamer built of iron or steel in Spain will be launched at Cadiz this week. It was built by the Transatlantic Company in their repairing shops and dry dock, established at the Trocadero, in Cadiz Bay.

ELECTRIC LIGHT COMPANY.—The Electric Light Company La Madrileña General de Electricidad, a half of which belongs to a group of German bankers and a half to the Gas Company, intend to increase their capital by £80,000, in order to establish two more stations. As long as the company are able to maintain their price of 1s. 4d. per 1,000 watts, their business is very profitable, but it is doubtful whether consumers will continue to acquiesce in this price.

GAS ENGINES.—The German company which manufactures gas engines of the Otto type is trying to extend their use in Spain. The company supplies them, together with the means of making some special gas for their working, and estimates that the expenditure of fuel will be 1 kilogramme per horse-power per hour. This seems to show that the gas is not Dowson's gas, which has been used in only one instance in Spain. Anthracite is found in Asturias, which can be easily worked, and gas coke is sold at Cadiz and Xerez at a lower price than that of coal.

TELEPHONE LINES.—Six direct telephone lines are to be laid between Madrid and some of the most distant provincial capitals. It is intended to connect all towns, including even the small ones, by telephone with the nearest telegraph station. At the present time there is great activity in the telegraph department.

NEW YORK, 17TH JANUARY, 1891.

LOCOMOTIVE BUILDING IN 1890.—The locomotive building in the United States by private firms was considerably more in 1890 than in 1889. In 1889, 16 firms built 1,860 locomotives. In 1890, 14 firms built 2,213, and, according to the *American Manufacturer*, several of those who have not yet reported were very busy through the year. It may, therefore, be concluded that the year's product has been materially greater than that of 1888, when 17 firms built 2,180 locomotives. Eleven of the firms that have reported up to date built over 18 per cent. more engines in 1890 than in 1889. All but two of those firms increased their output, and one of the two is the Grant Locomotive Works, which have been practically at a standstill for a good while. The Baldwin Works lead with 953 locomotives, an increase of 14 per cent. The Schenectady Works were the next largest builders, and their increase in output was over 53 per cent. The average yearly product of 19 firms for eight years, 1881-1888, was 1,645 locomotives. It will be seen that the product of each of the last three years has been far above that average.

RAILROAD REPRESENTATIVES' MEETING.—On the 8th inst. a meeting of representatives of all the Western railroads was held here in order to devise some plan for the formation of an advisory board to equalise and maintain rates. A motion was adopted for the appointment of a committee, consisting of one representative from each company, to report as to the bye-laws necessary for the carrying out of the purposes of the association.

RAILROAD IMPROVEMENT.—The third annual report of the Western New York and Pennsylvania Railroad shows a gratifying increase in all branches of the service. The net earnings have increased $311,144·50 over the preceding year, while the percentage of expenses has decreased from 78·3 to 69·4 per cent. In the nine months nearly thirty-one miles of new 67lb. steel rails have been laid, 176,000 ties put in the track, twenty miles of road ballasted, and important bridges renewed with steel, iron, and stone.

IRON AND STEEL WORKERS' WAGES.—Attempts are being made to change the basis of the scale on which the wages of iron and steel workers is based from bar iron to some other specialty which will give more nearly an average condition for the trade. Bar iron has been the basis for a good many years, but is of little moment when compared with iron and steel in other shapes. Either skelp iron or sheet iron has been suggested as fair basis, and a committee of the Amalgamated Association of Iron and Steel Workers are now collecting data by which an intelligent choice can be made.

THE SAULT STE. MARIE CANAL.—Some idea of the importance of this canal may be formed from the following comparative statement of the business passing through it for the seasons of 1890 and 1889:—

	1890.	1889.	Increase.	Per Ct.
Number of lockages	4,970	4,684	286	6
Number of vessels passed	10,557	9,579	978	10
Registered tonnage	8,454,425	7,221,935	1,232,490	17
Tons freight carried	9,041,213	7,516,022	1,525,191	20
Estimated value of freight	$102,214,949	$83,732,527	$18,482,422	22

The vessels passing the canal this year included 7,268 steamers, 2,872 sailing vessels, and 417 unregistered craft.

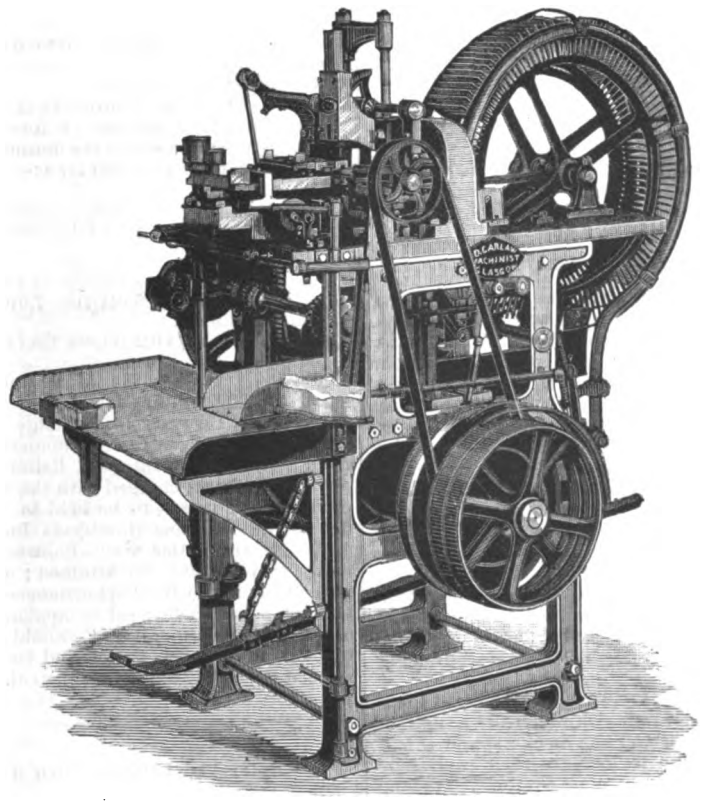
RAILWAY CONVENTION.—Judge Cooley, Chairman of the Inter-state Commerce Commission, has issued notices for a National Convention of Railroad Commissioners and any State officers charged with the supervision of railroads or railroad interests, to be held in Washington, on March 3rd, 1891. The general subjects for consideration as suggested in the notice are:—Railway legislation, how harmony therein may be attained; uniformity in railway accounting; statistics; apportionment of expense to freight and passenger traffic; safety appliances for railroad cars, and what legislation, if any, should be by Congress; the question of reasonable rates, and the elements to be considered in the determination thereof.

PHILADELPHIA, 16TH JANUARY, 1891.

RAILROAD STRIKE.—As a result of the refusal of the Chicago, Milwaukee, and St. Paul Company to accede to the demands of the station agents and telegraph operators on the line of that system a strike has been determined on, to begin to-day. The Chief of the International Order of Railway Telegraphers has ordered every station agent and telegrapher to send in his resignation. This course was taken by the men in order to protect their bondsmen, who would be liable for resulting damages if there had been a strike without previous notice.

BOBBINS.—The New England spool, bobbin, and shuttle industry seems to be going into the hands of foreign capitalists. The business has been a lucrative one, as the goods are used in all the textile mills. The present movement is supposed to have originated in the concern of Mr. H. J. Norwood, which is one of the largest in the East, having shops in New Bedford, Fall River, Woonsocket, R.I., and in Guilford, Me. Consumers of these articles are becoming interested in the matter, and threaten to establish a joint plant for manufacturing rather than allow a syndicate to dictate prices.

SUGAR.—The effect of the reorganisation of the Sugar Trust was seen in Boston when the properties of the refineries interested in the trust were re-leased to the America Sugar Refining Company, of New Jersey, which succeeds the Trust. The properties transferred in Boston amounted to $2,575,000. Over 160,000 Sugar Trust certificates were held in New England, and in the reorganisation holders of these certificates will be given one share of preferred stock, paying 1 per cent., and one share of common stock, which has averaged 10 per cent. for several years, for each two certificates presented for redemption.



GAS.—The report of the Bureau of Gas for this city for the past year gives as the total receipts $3,659,644·20, an increase of $1,419·37 over the previous year. The expenditure was $2,851,019·51, a decrease of $84,751·84. The total amount of gas made was 3,311,995,000 cubic feet in 1890, as against 3,151,156,000 cubic feet in 1889. The cash profits for the year amounted to $893,376 53, and adding to this $862,810·31 for 575,206,872 cubic feet used by the city departments, at $1·50 per thousand feet, makes the total profit for the year $1,656,186·84, an increase of $128,482·12 over the year 1889.

AMALGAMATION OF STEEL COMPANIES.—The Scranton Steel Company and the Lackawanna Iron and Steel Company's steel mill are to be consolidated, to enable the two companies to compete on better terms with Western mills, as it has been evident for some time that such a combination would be mutually advantageous. The output of the two mills will probably not be affected. An arrangement has been arrived at, and has been recommended at a meeting of the directors to the stockholders as desirable, and now awaits ratification by the stockholders. The output from the Scranton mills is nearly one-sixth of that of the entire company.

IMPROVED ENVELOPE FOLDING MACHINE.

CONSTRUCTED BY MR. DAVID CARLAW, 56, ROPEWORK LANE, GLASGOW.

IMPROVED ENVELOPE FOLDING MACHINE.

THE above illustration represents a new envelope folding machine, introduced by Mr. David Carlaw, 56, Ropework Lane, Glasgow, which possesses several novel features, including the use of boxed or inside cams, which obviate the necessity for springs in producing the different movements of the mechanism, and thus increase the smoothness of working and durability of the apparatus.

In the course of working the pile of prepared paper blanks is placed on a rest-plate in front of the machine. The blanks are then automatically raised, so that the top of the pile is maintained at a constant level in relation to the gumming and folding mechanism above. The feeding apparatus for accomplishing this may be lowered as requiring for replenishing, by means of a chain and treadle below the table of the machine. The blanks are lifted one by one from the top of the pile by brass picker plates, partially coated with gum. Two of these, making alternate movements, are employed, the required quantity of gum being imparted at each stroke by metal rollers, revolving in gum boxes.

The picker plates deliver the gummed blanks to a sliding carrier, which deposits them under a plunger, where they are creased and the flaps closed, with the exception of the seal flap, which is only partially folded over. At the same time, by means of an ingenious adjustable appliance, the envelopes have any desired amount of bulk, or roundness of the edges, imparted to them. This operation makes the envelopes more convenient for use, and also adds to their strength by lessening the liability to split at the edges.

After folding, the envelopes are transferred to wired divisions on the periphery of a revolving wheel at the rear of the machine, where they are dried by currents of hot or cold air forced through perforators in pipes coiled at the sides of the wheel. On reaching the bottom position of the wheel during its revolution the envelopes are dropped into a race, and gradually advanced to the front table to be banded by the attendant. All the operations, from the placing of the blanks to the receipt of the finished envelopes, are entirely automatic; and a single machine is capable of making from 30,000 to 40,000 envelopes per day.

THE GRAYDON DYNAMITE GUN.

The following interesting description of the Graydon dynamite gun appeared in the *Times* on the 27th inst.:—

The practically resistless energy developed by dynamite and other high explosives has long indicated them to be the best agents for producing a maximum destructive effect when used as bursting charges in shells for artillery fire. The difficulty, however, which has stood in the way of their practical application in this direction has been the great sensitiveness of such compounds to heat and concussion. It is easily conceivable that the blow exerted on the base of the shell by the explosion of the gun charge would cause the explosion of the bursting charge within the shell, which would thus destroy the gun and probably those serving it. This result might also be brought about by the heat generated by friction during the passage of the shell through the gun, which might cause the ignition of the bursting charge. Two things, therefore, have to be done—namely, to protect the charge of explosive so that the shell may not prematurely burst, and to eliminate, or reduce as far as possible, all concussive action at the moment of discharge. These two things have been accomplished by Lieutenant James W. Graydon, late of the United States Navy, in his dynamite shell and his dynamite gun. His shell is lined with asbestos cloth, which is an excellent non-conductor of heat as well as a cushion, and the charge of dynamite contained within the shell is divided up into small pellets or cartridges, each enclosed in a wrapper of waxed paper. These pellets are designed, first, to prevent the nitro-glycerine accumulating at any one point, should it exude from its absorbent; and, secondly, to cushion the charge and to prevent the shock from the propelling charge being transmitted to the dynamite in the shell in such a manner as to explode it.

Such, briefly, is the Graydon shell, which is to be discharged from the Graydon gun by means of highly compressed air, the bursting charge being 600lb. of dynamite, which is intended to be projected three miles in 30 seconds. The shell has already been tried in the United States, but with guns firing ordinary gunpowder. Three series of experiments were made there a year or two ago, the first of which consisted in firing several rounds from a 2·9in. field gun at the Presidio, San Francisco. The second series was carried out at Fort Winfield Scott, where 52 dynamite shells were fired from a 4·5in. siege gun. Later on the third series of experiments was carried out on a large scale at Sandy Hook, before the permanent Ordnance Board of the United States. Amongst others, a 7in. rifled gun was used, firing a 23lb. powder charge, with a 122lb. projectile, charged with 2¾lb. of dynamite. The target was part of an iron turret, 14in. thick, which was practically wrecked by two rounds, a third utterly demolishing it. Satisfactory as this was, there still remained the contingency of the blow on the base of the shell, imparted by the explosion of the gun charge, causing a premature burst in the shell. This point is met, as we have already indicated, by the propulsion of the shell being effected by compressed air in the Graydon gun. The first of these guns has been manufactured in this country by Messrs. Taunton, Delmard, Lane, & Co., of Birmingham, and has just been completed. This gun is to be discharged by the expansion of condensed air at a pressure of 5,000lb. per square inch, the impulse of which is a safer propelling energy than the ignition of any kind of powder, because it does not operate so suddenly as to cause danger of the premature explosion of the missile.

The dynamite gun has a tube or barrel made of Whitworth forged steel, 30ft. in length, and weighing about 11 tons. It is a smooth-bore, breech-loading gun, with a calibre of 15in. It is supported at the breech end on fixed trunnions 15in. in diameter, which are made hollow, for the passage of the compressed air into the gun. Towards the muzzle it is carried on movable trunnions, which engage with two steel arms or levers. These levers have sliding fulcra, and are actuated by a hydraulic plunger for the purpose of elevating or depressing the gun. The breech piece is a steel screw block with interrupted screw threads, as in heavy service ordnance. The gun is mounted on a carriage built of heavy steel plates, with trunnion bearings of cast iron secured to it by turned bolts. The carriage is supported on conical rollers running on a circular roller path. The rollers are geared together, and are actuated by a Heenan and Froude spherical quick-speed engine, the motive power of which is also compressed air. The roller path, which will ultimately be embedded in concrete, is 21ft. in diameter, and is made in sections of cast iron planed on the bearing surfaces. The gun can be trained for an all-round fire to the full circle of 360 deg. A peculiar feature of this gun is that it can be loaded at any degree of elevation within its working range. Pivoted to the breech trunnions is a loading slide or tray for the reception of the projectile or shell, which latter is 6ft. 3in. long, and weighs, with its bursting charge of 600lb. of dynamite, 1,300lb. The true flight of this shell is secured by a tapering, telescopic tail. By this telescopic arrangement Lieutenant Graydon is enabled to shorten the shell 50 per cent., and to reduce proportionately the length of the impulse tube. At all times when the barrel of the gun is elevated above the horizontal line the loading slide is raised by hydraulic pressure to receive the shell from a carrier running on a light tram line. By the opening of a valve the slide is caused to descend with the shell and to become in line with the barrel of the gun. On each side of the barrel is a small, double-acting, hydraulic cylinder, the plungers of which not only control the movements of the loading slide, but also, by their continued action, draw the shell up into the barrel, where it is held. The breech-closing block, which has hitherto been held suspended above the trunnions by counter-weights, then descends, and is also drawn into the breech by the cross-heads of the hydraulic plungers, and locked. The gun is now ready for being discharged.

The arrangements for effecting the propulsion of the shell from the gun consist, first, of a set of compressed-air reservoirs, thirty-two in number. These are 4ft. high and 10in. in diameter, and are made of metal ¾in. thick, tested up to a pressure of four tons per square inch. They are mounted on the gun carriage in four sections of eight each, two sections being placed on either side of the gun. Filled with air compressed to 5,000lb. per square inch, or about 1-340th of its original volume, the capacity of each at the working pressure is 17,000 cubic feet of air, weighing 11 cwt. in its compressed condition. Any number out of the four sections may be discharged, according to the range desired or the weight of the projectile. The discharging valves are a peculiar arrangement of the piston type, and are packed on the hydraulic system. The valves and pipes are of Whitworth steel, either forged or cast. The air is admitted from the reservoirs through the breech trunnions to the base of the shell, and the gun can be loaded, elevated, trained, and discharged by one person, who actuates a simple system of levers. It is stated that, if necessary, the shells can be discharged from the gun at the rate of one per minute.

The abnormally high pressure at which the air is used necessitated, as a matter of course, special apparatus for compressing it. The compressor adopted is one which has been devised by Mr. Lane, a partner in the firm which manufactured the gun. It is a modification of the

Digitized by Google

high-pressure apparatus invented by him and used for compressing oxygen, hydrogen, and carbonic acid gas. The air is compressed in four operations, the pistons decreasing in diameter at each stage. The first, which draws the air from the atmosphere, is 12in. in diameter, and the last, which delivers it to the reservoirs on the gun carriage, is 2¼in. in diameter. After each operation the air is cooled by a tubular coil surrounded with water. The air from the compressor is passed to the reservoirs on the gun carriage through a central pivot or swivel tube. The Graydon gun is now ready for trial by the British Government with live shell, but the place of trial has not yet been decided upon. The results of the trials will doubtless be looked for with much interest, as being likely to indicate the direction of a new and important development in warfare.

TRIPLE EXPANSION MILL ENGINE.

Our illustration on page 108 shows a type of triple-expansion engine constructed for driving machinery in mills and factories. The engine is constructed in three different sizes—viz., with cylinders 8in., 13in., and 21in., by 16in. stroke; 10in., 15in., and 25in., by 24in. stroke; or 14in., 22½in., and 37in., by 36in. stroke—and has been designed and constructed by Messrs. Ross & Duncan, Whitefield Works, Glasgow. The design secures economy of space by placing the cylinders overhead, as usual in marine engines. The three cranks are set at equal angles. In the engine we illustrate the condenser is of the ordinary jet type, but where necessary the same general construction can be combined with surface condensation. The air, feed, and injection pumps are worked by levers from the crosshead of the low-pressure engine, and are guided by brackets from the back of the columns. The cylinders are all fitted with indicator gear, and all drain and injection cocks are carried to the front of the engines. The high-pressure cylinder has a throttle-valve regulated by a high-speed governor, and has also Bremme's patent expansion gear to vary the cut-off. The crank-shaft is carried on six bearings, having bushes filled with white metal. The fly-wheel is cast in halves, and is made for belt or rope driving according to requirements. The advantages aimed at in this kind of engine are economy of space and fuel, smooth running, and symmetry of design.

SHIPBUILDING NOTES.

On the 17th inst. the s.s. "Glenisle," built by Messrs. Edward Withy & Co., Hartlepool, for Messrs. Livingston, Conner, & Co., West Hartlepool, was taken to sea for her trial trip. The vessel is built of steel and to the highest class at Lloyd's, and has a very large deadweight carrying capacity. She is fitted with triple-expansion engines by Messrs. T. Richardson & Sons, Hartlepool, with cylinders 20in., 31½in., and 53in., with 36in. stroke, and they have all the latest improvements for economy of fuel and efficiency in working. During the trial trip a mean speed of 11 knots was obtained, and the engines worked with great smoothness.

Messrs. Fleming & Ferguson, shipbuilders and engineers, Paisley, have received an order from the Union Steamship Company, of New Zealand, to build for them a steel screw steamer for their passenger and fruit trade between Fiji and New Zealand. This firm has also received an order for a steel screw yacht from Mr. Peter Coats (of Messrs. S. & P. Coats, Limited), Paisley, to be built to the design of Mr. G. L. Watson, naval architect, Glasgow. Both vessels are to be fitted by the builders with their patent quadruple-expansion engines.

On the 23rd inst. the ss. "Yung Ping," built by Messrs. Craig, Taylor, & Co., of Stockton-on-Tees, to the order of Messrs. Russell & Co., of Shanghai, New York, and London, and under the superintendence of Messrs. A. & W. Dudgeon, of 112, Fenchurch Street, London, was taken out to sea for her trial trip, which proved very satisfactory. The dimensions of the vessel are:—Length, 223ft.; breadth, 32ft.; depth, 13ft. 11½in. She is to trade in Chinese waters, and is fitted with teak decks. She has water ballast, and is classed 100 A1 at Lloyd's. The engines, by Messrs. Wm. Allan & Co, Scotia Engine Works, Sunderland, are 15in., 25in., and 41in., with 24in. stroke, and on the measured mile, after a number of runs, a mean speed of 9·8 knots was easily obtained, the weather at the time being fairly rough. The vessel, which was loaded, proceeded at once to China.

Messrs. Sharp & Kent.—In our account of the work done in electrical engineering during the past year a misstatement occurred which we regret. We should have stated that Messrs. Sharp & Kent supplied the engines, boilers, and "Goolden" dynamos, and the underground mains for the Houses of Parliament. This firm also supplied the boilers and dynamos to the Westminster Company, and have large orders for Brighton and elsewhere.

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, January 30th, at 7.30 p.m. Students' meeting. Paper to be read: "The Counterbalancing of Locomotive Engines," by Mr. E. L. Hill.

Royal Institution.—Friday, January 30th, at 9 p.m. Lecture on "The Rejuvenescence of Crystals," by Professor J. W. Judd, F.R.S.

Sanitary Institute.—Friday, January 30th, at 8 p.m. Lecture on "Ventilation, Warming, and Lighting," by Sir Douglas Galton, K.C.B., F.R.S.

Sheffield Society of Engineers.—Saturday, January 31st, at 7.30 p.m. Paper to be read: "Elliott's Smoke Annihilator," by Mr. C. F. Shrewsbury.

NEXT WEEK.

Society of Engineers.—Monday, February 2nd, at 7.30 p.m. Presidential Address by Mr. W. N. Colam.

Society of Chemical Industry.—Monday, February 2nd, at 8 p.m. Paper to be read: "On Standard Sperm Candles," by Mr. W. C. Young.

Royal Institute of British Architects.—Monday, February 2nd, at 7 p.m. Sessional meeting.

North East Coast Institution of Engineers and Shipbuilders, Newcastle-on-Tyne.—Monday, February 2nd, at 7.30 p.m. Discussion on the following papers: "The Unsinkability of Cargo-Carrying Vessels," by Mr. Hök, and "Main Steam Pipes," by Mr. M. Sandison. Paper to be read: "The Influence of the Relative Dimensions and Proportions of the Screw Propeller on the Vessel's Performance," by Mr. A. Blechynden.

Institution of Civil Engineers.—Tuesday, February 3rd, at 8 p.m. Paper to be read: "Electric Mining Machinery," by Messrs. L. B. and C. W. Atkinson, Assoc.M.M.Inst.C.E.

Sanitary Institute.—Tuesday, February 3rd, at 8 p.m. Paper to be read: "Principles of Calculating Areas, Cubic Space, &c.; Interpretation of Plans and Sections to Scale," by Mr. H. Law, M.Inst.C.E.

Owens College Union Engineering Society.—Tuesday, February 3rd, at 7 p.m. Paper to be read: "Stationary Engines," by Mr. A. Saxon.

Society of Arts.—Wednesday, February 4th, at 8 p.m. Paper to be read: "Decimal Coinage, Weights, and Measures," by Mr. J. E. Dowson.

PRICES CURRENT, 28th January, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

„ English Ingots	94	5	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: Very steady, and prices unchanged. Demand continues slow, and the amount of business small. Chili bars have fluctuated but slightly of late, quotations to-day being the same as on the 21st—viz., £53 2s. 6d. to £53 7s. 6d. cash, with moderate sales reported. Manufactured quiet at £65 to £66, "strong."

Tin shows a weaker tendency, values having declined during the last few days.

Lead: Dull, with small demand, but values unchanged.

Spelter continues firm, and prices advancing, owing to small supplies.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: The values of all articles controlled by the Chemical Union are firmly maintained, and any small re-sale parcels that may be available are only to be obtained at a very slight discount upon Union prices. Caustic soda is rather slow of sale, but its value is not affected. More business is passing in acetates of lime, and prices are firmer. Acetate of soda is scarce on spot. Acetates of lead in fair inquiry. Nitrate of lead dull.

HOME INDUSTRIES.

LONDON, 29th January, 1891.

THE MONEY MARKET.—The abnormally small demand for money keeps rates very low, in spite of a well-maintained outflow of gold, chiefly to Holland. Loans for short periods are in excess of the demand, and those who have balances to lend find it almost impossible to employ them, even below ¾ per cent. Discount rates are also very easy, the fact that three months' Treasury Bills were allotted in the beginning of the week at 1⅛ per cent. giving a fair idea of the condition of the market. Stocks have been inactive and generally dull, the settlement affording a good excuse for a relaxation of even the small amount of "professional" dealing that had been going on. The settlement has been chiefly interesting because of the insight afforded into the state of the account in home railway stocks. The falling off in dividends through the increase in working expenses has induced speculative "bear" selling on a considerable scale, but investors do not seem to have been alarmed into parting with their securities, and stock has been very scarce. The experience has been the same in most departments of the market, but the usual consequence of an oversold account—a revival in prices—has not followed. The more select investment securities are firmer in consequence of the abundance of money and the difficulty of employing it, but other departments are dull in tone.

ACCESS TO THE EMBANKMENT.—A plan has been proposed by Sir J. Whittaker Ellis, M.P., for improving the access to the Embankment, and also for widening the Strand, in order that the traffic over Waterloo Bridge from the South of London may be facilitated. In a letter addressed to the London County Council, he suggests that that portion of Wellington Street lying between the Strand and Waterloo Bridge should be widened on the western side to the frontage of Lancaster Place, and that the roadway of Waterloo Bridge should be thrown out on each side to an equal width by carrying it out in its present form to the water-line of the Embankment. A roadway, say, 60ft. wide, should then be run down parallel with the Embankment itself to the Embankment level. These spurs from the bridge, which would take a gradient of 1 in 33, would take all the traffic going east or west from Waterloo Station and the South of London. They would also be convenient for the relief of the Strand itself east and west. These improvements would afford readier access from the Strand eastwards to the Temple Station, and westwards to Charing Cross along the Embankment.

THE JUNIOR ENGINEERING SOCIETY.—The sixth annual dinner of this flourishing Society was held at the Holborn Restaurant on Friday evening last. Professor S. P. Thompson, B.A., D.Sc., presided. The growth of this Society, which numbers amongst its past and vice-presidents some of our leading engineers, has been exceedingly rapid. At the commencement of the present session the membership roll, including honorary members and associates, numbered 180, as against 88 during the preceding session, showing an increase of more than 100 per cent. We are informed that it is the intention of this Society, at an early date, to further add to its useful features an employment bureau for the use of members disengaged.

THE SANITARY INSTITUTE.—Donations to the amount of £600 have been made to the Institute during the past year by the honorary officers and members of council, and a considerable portion of this amount has been devoted to re-arranging and improving its museum of sanitary appliances, and to the preparation and printing of a catalogue. The museum being open free to the public, want of funds has hitherto prevented the Council from undertaking this work, although they long felt it to be much needed in order to make the teaching of the museum fully available to the public.

BOWMAN'S OXYGEN LIGHTING COMPANY.—This company have stated that they will not proceed any further with their Bill in Parliament for the generation and supply of oxygen to the metropolis. The Bill included powers to lay mains for the supply of oxygen, and to make agreements with the gas companies for the use of oxygen in combination with coal gas, in order to increase its illuminating power.

BUSINESS ANNOUNCEMENT.—The Delta Metal Company, Limited, of 110, Cannon Street, E.C., inform us that they have appointed as secretary Mr. Y. W. Meyjes, who has been connected with that company for several years.

THE WHITECHAPEL CRAFT SCHOOL.—Practical handicraft classes in carving and modelling suited to the needs of wood carvers, cabinet makers, and stonemasons are held on Friday evenings, at 8 p.m., at the Whitechapel Craft School, 27, Little Alie Street, E.

CALENDAR.—A calendar for the year 1891 has been issued by Messrs. Shand, Mason, & Co., Blackfriars Road, London, makers of steam and manual fire engines, which contains a well-executed illustration of a steam fire engine, from a picture by Mr. J. Charlton.

EXHIBITION OF METEOROLOGICAL INSTRUMENTS.—The Council of the Royal Meteorological Society have arranged to hold at 25, Great George Street, Westminster (by permission of the Council of the Institution of Civil Engineers), on March 17th to 20th next, an Exhibition of rain gauges, evaporation gauges, percolation gauges, and kindred instruments. The Exhibition will also include any new meteorological instruments invented or first constructed since last March Intending exhibitors should make application to Mr. W. Marriott, the assistant secretary, 30, Great George Street, S.W., not later than the 10th prox.

MANCHESTER, 29th January, 1891.

THE IRON TRADE.—The general trade in pig iron in this district is very languid, and this has been a very dull month. Although few engineers or ironfounders are short of work there has been no inclination to buy, and except for absolutely necessary purchases little has been done. Prices have consequently drooped, and there is a total lack of firmness in this trade. Bar iron is weaker in tone, and lower prices are ruling. At present prices of fuel and raw material, and with existing rates of wages, the manufacture of bars is much less profitable than it has been for about two years. Although the frost has not been so keenly felt as in some districts, it has had an effect upon trade, and has aided in bringing about the present depression.

THE SHIP CANAL.—The works of this undertaking narrowly escaped flooding again on the 24th instant. A large volume of rain fell in the Mersey and Irwell valleys, and as there was a good deal of snow on the ground the rivers rose rapidly. The only serious damage done, however, was to the brickfield at Lymm, which was for the second time flooded. The flooding in the Medlock led to the backing up of the water into an old sewer and caused a flooding of one of the sections of the new intercepting sewers which are being constructed by the Manchester Corporation.

THE ENGINEERING TRADES.—Employment in the engineering trades is good, the returns from local branches of the trade societies showing that only about 2 per cent. of their members are out of employment. In millwrighting work there is plenty of employment, and the same remark may be made of boiler-making, tool-making, and locomotive works. In cotton machinery extreme activity prevails, and this department continues to be actively employed. Improvements are being made in preparing machinery, both Messrs. Platt Bros. & Co., Limited, and Messrs. Asa Lees & Co., Limited, being engaged in introducing improved opening machinery with a view of getting more even laps.

THE LINEN AND JUTE TRADES.—There has been a steady movement during the week, the setting in of mild weather having stimulated business considerably in several departments. There is no perceptible weakness in prices of linen goods, manufacturers, both of low and better class makes, being firmly resolved to maintain prices at their present level. Spinners also preserve an attitude of firmness, and there appears to be little prospect of goods becoming cheaper just yet. Drills for export are slow of sale. Light damasks for the home trade meet with inquiry. The shipping trade is still quiet, both on South American and United States and Canadian account. There is no fresh news from Chili, and local shippers are now awaiting the arrival of the mails, as all hope of obtaining reliable news through the medium of the cable has been abandoned. Further failures in Canada tend to increase the gloom caused by recent events, and commercial enterprise is kept within very limited bounds, owing to the prevalent uncertainty.

BRONZE ALLOYS.—A company was registered on the 12th inst. to acquire an invention of Mr. Joseph Elton Bott, for improvements in the manufacture of bronze alloys, and to carry on the business of iron and steel founders, engineers, and boiler makers. The works will be at Openshaw.

GLASGOW, 29th January, 1891.

THE SCOTTISH RAILWAYS.—The Bill of the North British Railway Company for the acquisition of the Glasgow and South-Western Railway has been found to comply with the standing orders of the House of Commons, and will shortly come up for discussion. Sir John Burns, of the Cunard Line, who announces himself and his family as the holders of £80,000 of stock in the Glasgow and South-Western Company, has written a circular to his fellow-shareholders, protesting against the sale of the line to the North British Railway. Besides this, it is rumoured that the Bill will be received with opposition on all sides. Whatever may be the public opinion upon the conduct of the strikers, and whatever may be the relevancy of that topic to a discussion of the merits of the Bill, the North British Company has undoubtedly done much to revive the adverse feeling which existed against it in the public mind a few years ago. Such feelings had been almost obliterated by admiration for its energy and enterprise, especially in connection with the construction of the Forth Bridge and the reconstruction of the Tay Bridge.—The Caledonian Bill for the acquisition of the Glasgow and South-Western Railway by that company has been withdrawn. This is said to indicate an attempt at agreement between the companies, and a probable re-arrangement, especially as regards the Edinburgh and Glasgow traffic. At present the two railways share in the receipts in the proportions of two-thirds to the North British and one-third to the Caledonian.

THE RAILWAY STRIKE.—The Scottish railway strike is now in its sixth week. The men of the Glasgow and South-Western Railway returned to their work some weeks ago, and the Caledonian men have now almost all returned; but the North British Railway Company is still in difficulties with its men. The latest phase of the struggle, which even yet shows no definite sign of ending, is the institution of a civil action by the North British Railway Company against the executive of the men's union. The company demands £20,000 damages for injury to its business caused by the action of the executive. In addition to bringing this action the company also employed a process of law in Scotland called "diligence," which is now rarely resorted to, and seized by arrestment the effects of each of the members of the committee of the men. The company has succeeded in attaching a sum of about £3,000 of strike funds. These funds had been received by the committee from day to day from other trade unions and from the general public. The affair is a new development in the recent history of trade unionism, and has caused considerable excitement in Scotland.

STATE OF TRAFFIC.—Traffic has considerably improved. The mineral service still suffers considerably, and on some of the lines reduced services of passenger trains are being carried on. Although the worst period of the strike is now felt to be at an end, there is still a large number of men out, and their places are filled by inexperienced men. This fact must still give rise to anxiety.

THE ACCIDENT AT THE CORPORATION GAS WORKS.—Sir William Arrol and Messrs. George Livesey, Charles Hunt, and Andrew Gillespie were asked to report upon the cause of the recent explosion of two gas-holders at Maryhill. They have reported to the effect that they "found indications of some explosive material having been placed on the crown" of one of the holders, that the explosion penetrated inwards, and that the concussion was sufficient to rupture the plates of the second holder, which was also destroyed. They also report that the gas simply burned away without causing any damage either to the remainder of the works or to the neighbourhood, The authorities have offered a reward of £1,000 for the discovery of the perpetrators of the outrage. An independent report will be submitted by Colonel Ford and M. Dupré to the Home Office. It will be remembered that this is the second time that such an outrage has happened in Glasgow. One of the gas-holders at the Tradeston works of the Corporation was destroyed in 1883 by precisely similar means. In that case the deed was traced to a Fenian conspiracy.

CHEMICAL INDUSTRY.—Steps are being taken towards forming a Chemical Section in connection with the Glasgow Chamber of Commerce similar to those which exist in the London and Manchester Chambers. Its object would be to look after the interests of the chemical and allied trades of the West of Scotland, and to advise as to legislation towards enabling them to compete with foreign nations under fairer conditions than at present exist.

(From our own Correspondents.)

LIVERPOOL, 28th January, 1891.

THE LIVERPOOL ENGINEERING SOCIETY.—A large number of the members of this Society met on the 21st inst., at the Highfield Street Station of the Liverpool Electric Supply Company, and were conducted over the works by Mr. A. B. Holmes, M.Inst.C.E., one of the engineers to the company. An inspection was made of the whole of the machinery, meters, and testing apparatus, and the members afterwards adjourned to the Royal Institution, when Mr. Holmes read a paper upon what they had seen. To illustrate the growth of the company's operations, he mentioned that in January, 1888, the number of 16-candle lamps connected with the company's stations was 997; in January, 1891, the number had risen to 11,750. The company have now three stations, having a total capacity of 15,500 lamps, and capable of extension to 37,000 lamps. The system adopted was a direct current continuous supply, at a pressure of 110 volts, all the mains being in simple parallel. The accumulators are made by the Electric Construction Association and by the Crompton-Howell Electric Supply Company, and have a storage capacity of 1,700 ampere hours at ordinary rates of discharge. The largest feeding mains were composed of ninety-one No. 7 wires, having a sectional area of 1·51 square inches. The total length of single cable laid in the mains was 41 miles; there were 10 miles of feeding mains, 9 miles of distributing mains, and 1¼ mile of service line. The weight of copper in the mains was 210 tons.

THE MERSEY TUNNEL EXTENSION.—An opportunity was afforded, on the 23rd inst., for a party of local engineers and others to inspect the extension of the Mersey Railway from the James Street Station to the Central Station at the bottom of Bold Street. The tunnel is now practically completed, and the permanent way is laid and ballasted down Lord Street. The station which is underneath the Central Station is far advanced, and operations have been going on underneath to within a foot of the rails of the Cheshire Lines Railway, this part of the work being very difficult, and attended with considerable risk in consequence. The line to Bold Street will be open for traffic towards the end of June next. The work is being carried out by Messrs. Waddel & Son Mr. Francis Fox being the chairman and engineer of the company.

LEEDS, 28th January, 1891.

THE IRON AND STEEL TRADES.—Compared with the opening of 1890, the past fortnight has been quiet, though the feeling with regard to the iron and steel trades is perhaps steadier than was the case even a week ago. The quietness of the shipping trade is being felt, but some of

Digitized by Google

the large firms are in the position of being able to give their workmen employment in other directions. A fairly large quantity of material is being turned out at the steel rolling mills. The Leeds Forge Co. continue very active, much business being done in steel bogie frames, both on home and foreign account. With reference to the engineering shops, a large number of tank locomotives are in course of construction, while contracts for the larger class of railway engines are as yet by no means exhausted. It is reported that large contracts for locomotives for foreign railways will shortly be offered, and if there should be truth in the rumour local engineers will expect to receive some of them for Leeds. The shops where specialties are manufactured seem to be still well occupied, and employers generally can keep their hands on full time.

THE COAL TRADE.—During a greater part of the last two weeks the coal trade was disorganised owing to the waterways of West Yorkshire being frozen. In Leeds householders particularly suffered from the severe frost, in that they had difficulty in obtaining coal for domestic purposes. At the time of writing, however, matters have assumed their normal condition, prices remaining firm. The recent bad weather was not taken advantage of for the increasing of quotations.

SHEFFIELD, 28TH JANUARY, 1891.

IRON AND STEEL.—A large amount of trade continues to be exported from this district, and although some of the large contractors are becoming anxious at the cessation of inquiries for new work, there is at present no cause for alarm. There are a few good orders for crank-shafts of cruisers and gunboats to be built or re-engined under the new naval programme. These are all forged under hydraulic pressure from special ingots of Siemens steel, and, however well forged they may be, a good deal of heavy machining has to be done in the shops. Almost all marine cranks under 16in. diameter are now forged solid, both for triple-expansion and for compound engines. The marine engineering trades are rather quiet just now, and little work of a special character is being done here. Some very fine gun forgings are being sent out rough machined, both for the home and for foreign Governments.

RAILWAY MATERIAL.—Manufacturers of rolling stock and railway material generally are fully employed. The last three years have been very prosperous, the machinery of some firms having run night and day during the whole of this period. There is, however, a bad time coming, as the producing power is now largely in excess of the requirements. The Manchester, Sheffield, and Lincolnshire Railway Company are pushing on with their Beighton extension, and have already completed the heavier portions of the cuttings.

NORTH STAFFORDSHIRE, 28TH JANUARY, 1891.

THE IRON TRADE.—Prices of pig iron and the finished material show a weaker tendency, and in some cases are now actually below the cost of production. Forge pig iron realises from 42s. 6d. to 45s. at makers' works, according to quality. Bars are quoted at £6 to £6 5s. per ton delivered at Liverpool. The outlook is also discouraging, orders and specifications being scarce, and competition very severe.

CHATTERLEY COLLIERIES.—The prospectus of the Chatterley-Whitfield Collieries, Limited, has been issued this week. The company has been formed with a capital of £400,000, and a debenture issue of £200,000, to take over the business of the Chatterley Iron Company, which has for many years been in liquidation. The profits for the year 1890 are certified as having amounted to £52,977.

BIRMINGHAM, JANUARY 28TH, 1891.

THE IRON TRADE.—Business generally in iron and iron goods is quiet, though there is a slightly better tone in the hardware stamping trades and hollow ware trades. Bicycle manufacturers are busy, and they keep the makers of light stamped forgings in full work. Bridge builders in the Dudley and Wednesbury districts have not much on hand, but boiler makers are busy, as also are tube works of all kinds. Edge tool makers and manufacturers of spades, shovels, and anvils find a better demand.

ADMIRALTY CONTRACT.—The Admiralty contract for bar iron has been placed with the Butterley Iron Company, Derbyshire. It has been executed by the New British Iron Company, Cradley, during the last seven years, and the 14,000 or 15,000 tons supplied in that time have given great satisfaction at the Government Dockyards. The iron for these contracts is all tested at the works of the contractors, both for tensile test and smithing qualities.

LEICESTER, 28TH JANUARY, 1891.

WOOL SPINNING AND YARN TRADES.—The amount of business doing in the local wool market has been steadily increasing, especially in the best kinds of English wools. There has been no further advance in prices, but the market is very firm at current rates. There is no speculative business, and consumers are awaiting the results of the London sales of this week. Skin wools sell freely, and lustres and demi-lustres are more inquired for. Good hog and half-hog fleeces make 23s. to 24s. per tod; superior, 24s. to 26s. per tod; choice lots, 26s. to 27s. per tod. Spinners are a little better employed than they have been, but the advance in the price of wool has lately prevented their accepting contracts at the low current quotations. There is a decided increase in the amount of business on offer, and, in the face of this, spinners are trying for better prices. Cashmere yarns are in good demand.

HOSIERY TRADE.—This industry is in a very healthy condition. There is a large business in most departments of plain hosiery. The long-continued cold weather has almost cleared stocks of underwear, and the glove and heavy hose departments have shared in the good business done. The prospects for both home and shipping trade are very encouraging. The fancy department is beginning to exhibit signs of increased activity, and sampling is very brisk. There is rather a general complaint that prices are very low, and the profit margin narrow.

SWANSEA, 28TH JANUARY, 1891.

INDUSTRIAL INCIDENTS OF THE FROST.—Llanelly, which throughout the frost has been well supplied with water, was seriously inconvenienced on the 24th inst. owing to the total cessation of the supply. Fearing an overflow over the damaged waste water weir of the Cwmlleidi reservoir, the repairs to which had been interrupted by the appearance of the frost, the flood-gates and the sluices were opened to lower the level and the water run into the river, with the effect that operations were brought to a standstill in the majority of works in the tinplate town. The frost has also caused serious inconvenience at the Dowlais Works, where, in the cogging mills, nearly forty hydraulic and pressure pipes burst during the recent severe weather. The mills had of necessity to be closed until repairs were effected.

STRIKES AVERTED.—Mr. Mannesmann has granted an advance of 2s. per week to all the smiths at his tube works after a conference with the officials of the Amalgamated Society of Engineers, the Dockers, and the Welsh Artisans' Unions.—The "flux" dispute at the Duffryn Tinplate Works has been amicably settled, the men having returned to work in accordance with the terms of a resolution of their union executive.

THE ELECTRIC LIGHT.—The directors of the Gwendraeth Tinplate Works have decided to adopt the electric light, and the installation is in a forward state.

CARDIFF, 28TH JANUARY, 1891.

IRON AND STEEL.—The new Plymouth Collieries Company, Limited, may possibly revert to the manufacture of Welsh bars or Bessemer steel, but the distance from the seaboard, where most of the large steel and iron makers are looking for prospective sites, makes such a course improbable. The manufacturing trade is in an unsatisfactory condition. While the price of tinplate bars, as well as steel rails, is decreasing, foreign ore is advancing, and even at high figures good ore is difficult to obtain. Some contracts for Bilbao ore have been entered into for shipment over the year at higher prices than were recorded at the top of the boom a year ago.

COAL MARKET.—The steam coal market continues active, and prices show little change. No. 1 quality is quoted at 15s. 6d. to 16s.; No. 2, 14s. 3d. to 15s. 3d.; No. 3 13s. 6d. to 13s. 9d.; and No. 4, 13s. to 13s. 3d.

BARROW-IN-FURNESS, 28TH JANUARY, 1891.

HEMATITE.—The business done during the week has been comparatively small. Orders have not been offered on a large scale, and the work in hand will not probably extend over more than three or four months. But the consumption of Bessemer pig iron has been lessened by reason of the fact that steel makers are not using so much as they were, and when this is coupled with the paucity of the general demand, and the fact that stocks have been gradually increasing of late, the wisdom of the action of makers in reducing the output of pig iron is at once demonstrated. Five furnaces have been blown out during this month—one at the West Cumberland Works at Workington, one at the Solway Works at Maryport, and three at the Moss Bay Iron and Steel Works, where also the steel-producing plant has been indefinitely brought to a standstill in consequence of the inability of Mr. Peet, the official liquidator, to make iron at a profit, and the indisposition of the men to accept lower wages. There are now forty-five furnaces in blast, and at this time last year fifty-six were producing iron. Prices are easier, at 53s. for warrant iron, net cash, and 53s. 6d. to 54s. for parcels of mixed Bessemer numbers, net f.o.b. Makers say it is impossible, with iron ore at 11s. 6d. and coke at 21s. to 22s. per ton, to sell iron at lower prices than those they quote.

STEEL.—Makers are well employed in most departments, and have orders in hand which will keep them busy for some three or four months to come, both in the rail and in the general departments of trade. Prices are not materially changed, except so far as regards tinplate bars, which are quoted at £5 per ton.

TUBULAR FRAME WAGGONS.—It is very probable that next week a new company will take possession of large works at Barrow, with a view of commencing the building of tubular frame waggons on the American freight car principle at Barrow.

MIDDLESBROUGH, 28TH JANUARY, 1891.

PIG IRON.—The tone of the market yesterday was rather better. No. 3 G.M.B. was inquired for at 42s. 3d., but sellers asked 42s. 6d., so there was not much business actually done. Inquiries for forward delivery are beginning to be more numerous, which is a healthy sign. For delivery over the first quarter 42s. 9d. was offered. In warrants Middlesbrough are quoted at from 42s. 1¼d. to 42s. 3d. Hematite East Coast brands are quoted at 55s. per ton mixed numbers makers' iron, and West Coast at from 52s. 10¼d. to 53s. cash. The stock in Connal's store is still increasing, standing at 122,407 tons on the 26th inst., being an increase since the beginning of the month of 6,520 tons.

SHIPMENTS OF PIG IRON.—These are improving, but mainly on account of the heavy shipments to Scotland. Up to the 26th inst. the shipments for the month amounted to 37,333 tons, 18,028 of which went to Scotland, against 7,615 over similar period last year. The continued frost has lessened the Continental demand for the present.

MANUFACTURED IRON AND STEEL.—There are more inquiries and a better feeling. Prices remain much the same. Iron ship plates, £5 15s.; angles, £5 10s. 6d.; bars, £5 15s. per ton; steel ship plates, £6 5s.; angles, £6 5s.; rails (heavy), £4 17s. 6d. per ton, all less the usual discount f.o.t. at works. The average net selling price per ton of manufactured iron for the last two months of the year, as certified by the Arbitration Board's accountant, was £5 19s. 9d. per ton. Rails sold during that period at £5 15s. 10·03d., plates at £5 18s. 10·87d., bars at £6 2s. 8·24d., angles at £5 15s. 7·68d. per ton.

NEWCASTLE, 28TH JANUARY, 1891.

IRON AND STEEL.—In the finished iron trade, though prices have receded to the point at which they stood six months ago, a tone of firmness now exists, and there appears to be little likelihood of any further depreciation of values taking place during the first quarter of the year. The manufacture of steel plates will soon be commenced at Gateshead by Messrs. Ibbotson Bros., of Sheffield, and at Newburn by Messrs. John Spencer & Sons, who are now rapidly completing extensive mills for the purpose. The Consett and Jarrow Steel Works are very busy.

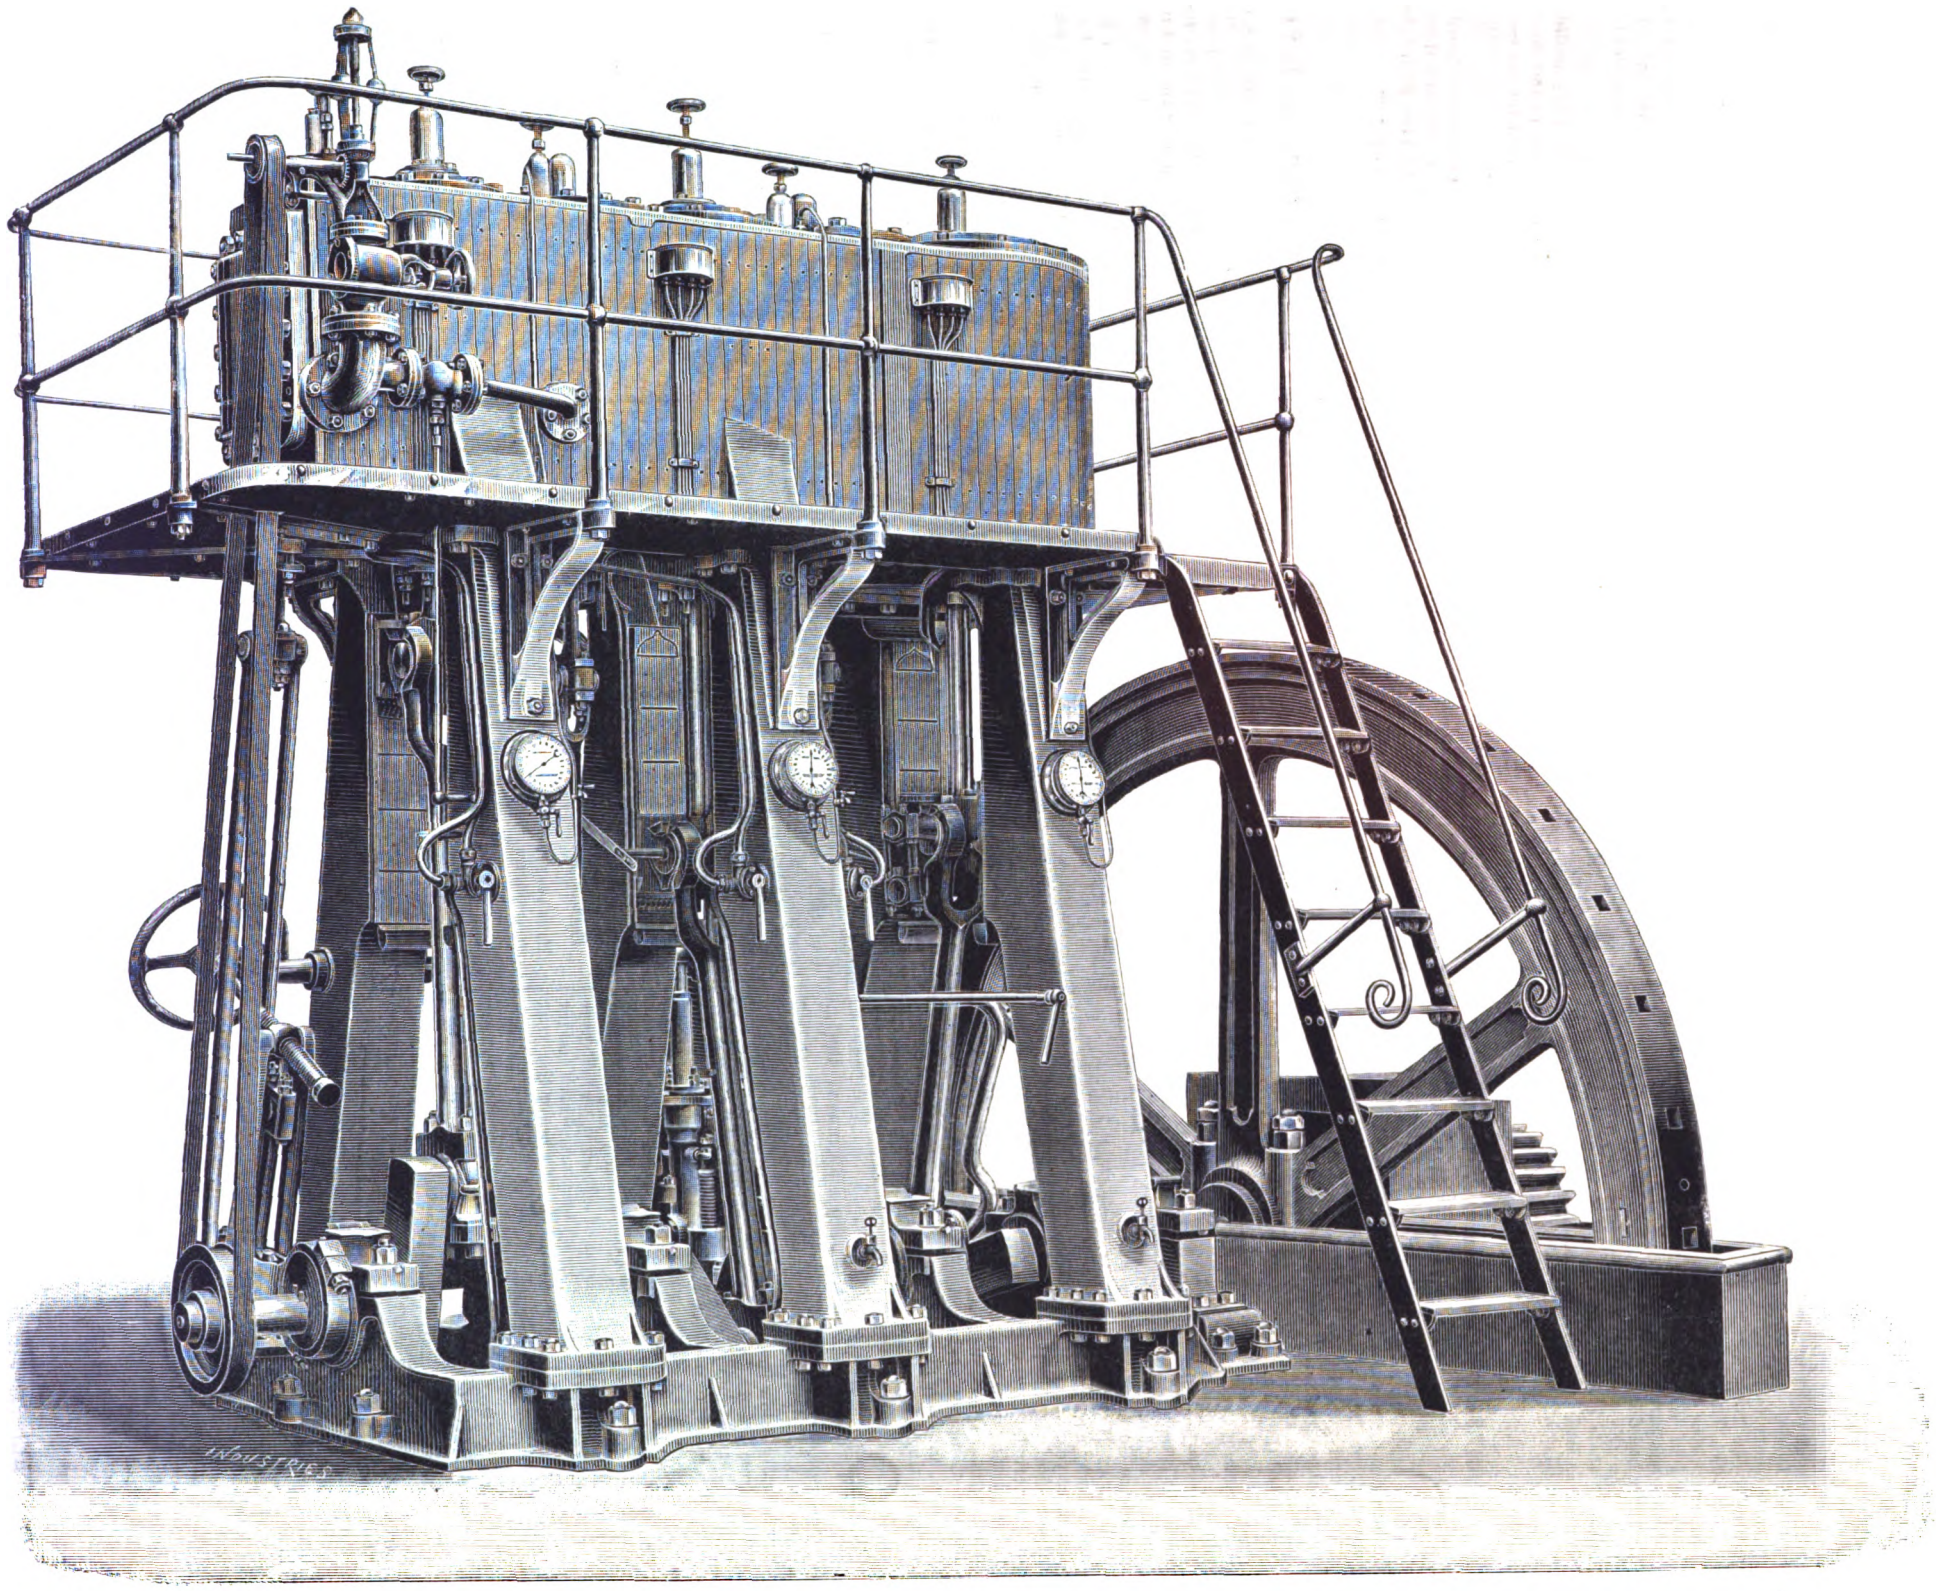
THE COAL TRADE.—The shipment of coal and coke at Tyne Dock during the week ending the 24th inst. amounted to 108,761 tons, being an increase of 6,417 tons as compared with the shipments in the corresponding week last year.

ENGINEERING.—The pressure of work at the St. Peter's establishment of Messrs. Hawthorn, Leslie, & Co. shows an increase, and if the firm had not an extensive range of shops at Forth Banks, to which they can send some of the subsidiary parts of engines to be machined and fitted, they would scarcely be able to make the necessary progress with their many important contracts. The firm are also utilising the resources of the Forth Banks boiler works—where only locomotive boilers are usually dealt with—for the execution of part of the marine work, and two marine boilers of large size are now in course of construction at the latter place. On the whole, the firm are perhaps better supplied with engineering work than any other in the district. Messrs. Tangye & Co., of Birmingham, have just supplied through their Newcastle agency two 30in. centrifugal pumps to Messrs. John Readhead & Co., South Shields. These pumps, which are to be used in connection with the working of a large graving dock in the vicinity of Messrs. Readhead's shipbuilding yard, will be among the largest and most powerful in the district.

ELECTRIC LIGHTING OF WYNYARD.—One of the largest private house electric light installations in England will be that at Wynyard, Lord Londonderry's country seat in Durham, the contract for which has recently been given to Messrs. Drake & Gorham. It will comprise 753 incandescent lamps, together with a steam power electric generating plant of large dimensions. Mr. A. A. Campbell Swinton has been appointed consulting engineer to superintend the work on Lord Londonderry's behalf.

DUNDEE, 28TH JANUARY, 1891.

JUTE AND FLAX TRADES.—There is little change in the industries of this district. Cable advices from Calcutta state that loose and baled jute are in active demand and prices firmer. In New York, burlaps, 40in. 10¼oz, are quoted at 4 1/16c. per yard, and light weights at 4 9/16c. The demand in the American market has considerably improved during the last few weeks. A good business has been done here in raw jute, and prices have advanced from 15s. to 20s. from the lowest point. The jute yarn market is quiet, and the improved demand for jute goods has scarcely been maintained here. In flax few transactions are reported. Holders are asking firm prices, and spinners, being well supplied for immediate wants, are not disposed to offer. Prices of flax yarns are low, and there is a fair business.



APPOINTMENT.—Mr. T. Claxton Fidler, M.Inst.C.E., London, has been appointed to the Chair of Engineering in University College, Dundee, rendered vacant by the election of Professor Ewing to the chair formerly held by Professor Stuart in Cambridge University.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 30TH JANUARY, 1891.

PRIVATE BILL LEGISLATION.

THE subject of private Bill legislation has for a good many years been frequently discussed, especially in Scotland, and the name of the late Mr. Craig Sellar is prominently identified with the question. Mr. Sellar and those who acted with him thought it was a great hardship that when Scotch corporations or private individuals wished to carry out any engineering work, or do anything which required the permission of Parliament, they were compelled at great expense to journey to London and bring all their witnesses with them. Mr. Sellar several times introduced a Bill for having the investigations carried on in the localities concerned. Vested interests in this matter are generally very strong, and the progress made was slow. Three years ago, however, a Joint Select Committee was appointed by the two Houses of Parliament to inquire into the matter, and to report how far, and in what manner, without prejudice to the public interest, the present system might be modified with a view to the benefit of suitors, the economy of the time of Parliament, and the reduction of costs and charges. The Committee reported in favour of the devolution upon a Commission of the duties relating to private Bills, which at present are performed by Committees of the two Houses. The Government has introduced a Bill founded on that Report, as regards the nature of the Commission, the local inquiry which it is to hold, the relation in which it stands to Parliament, and the measure of control which Parliament will retain over private Bill legislation. The Bill at present before Parliament relates only to Scotland, and as it has passed its second reading by a majority of 64, and is to be pushed forward with all the influence of the Government, it may be well to consider some of the arguments which have been put forward in its favour, and also some of the objections to it.

We suppose that the reason why the Bill has been confined in its operations to Scotland is that the subject has excited more attention in Scotland than in other parts of the kingdom, but we are of opinion that this is not a good principle on which to arrange the legislation of the country, as it places in the hands of energetic agitators an amount of influence which they ought not to possess. The Government of the day should arrange its legislation strictly according to the wants of the country, and should as far as possible make its measures, at least all those of a general kind, applicable to the whole country. In the matter of private Bill legislation, it is difficult to see that what is good for Scotland should not at the same time be good for England and Ireland. The Report of the Committee stated that the convenience of suitors had pointed strongly towards local inquiry as being the best method of informing Parliament of the facts relating to such questions as are dealt with by private Bills. The Lord Advocate, who introduced the measure, while praising highly the ability and attention of Parliamentary Committees, pointed out some of the weaknesses of the present system, and indicated his preference for such a body as the Railway Commissioners. It was therefore proposed that the Commission should consist of a Judge of the Court of Session, a Railway Commissioner, a Member of Parliament, and a fourth to be appointed by the Court of Session. The decisions of this Commission are to be by no means absolute, but only to take the places of those of the Parliamentary Committees of the two Houses—that is to say, that the House of Commons should reserve its judgment on the scheme on the second reading, and should deal with the report of the Commission on the third reading, as it had hitherto been in the habit of dealing with the report of the Committees of the House. The Commission was to perform its duties in the following manner:—First, it would sit in the locality; secondly, it would sit out of as well as during the Parliamentary session; and thirdly, it would sit *de die in diem*.

The question for the public, especially that part of it connected with engineering and industry, to consider is whether this measure will make arrangements which are preferable to those at present in existence. Mr. Littler, Q.C., is strongly of opinion that it will not. It may, perhaps, be urged that he is an interested party, but he points out that he and men like him are likely to benefit pecuniarily by the operations of the Bill, for no one supposes that Scotch suitors will not—at all events for some years to come—seek the benefit, like all other suitors, of technical knowledge and experience, and, if so, they will have to pay considerably more, as election petition business proves, for making the inquiry a local one. As to distance, Mr. Littler considers that Glasgow is practically nearer to London than many English towns, so that it is absurd to treat Scotland exceptionally. The Bill proposes that the business should begin, as now, in Parliament, and, if it is unopposed, should be concluded there. At present, if there is opposition, counsel, engineers, chemists, and other witnesses are, as a rule, on the spot. The present tribunal, according to Mr. Littler, costs nothing, except the outrageous fees which the Houses themselves extort from the unhappy suitor. He thinks, however, that the proposed Commission will be far more costly, and he estimates its expense at £10,000 a year, while the expense to the suitors will be increased. He suggests that the present method might be much cheapened by abolishing House fees and keeping big deputations at home. In his opinion the Bill is worse than useless, for it is mischievous, and its only friends, so far as he can learn, are some busybodies from the Royal burghs and some briefless advocates in Edinburgh.

This may seem rather strong language, but it has been endorsed by experienced men in Scotland. Mr. Henry Lamond, who has had much experience in dealing with Scotch Parliamentary work, thinks that those persons who are urging the Government to pass this measure have not correctly diagnosed the causes of the expense and delays in private Bill legislation of which they complain, and therefore are not well fitted to suggest remedies. In addition to other objections, he points out that when the Bill is reported to the House, and the promoters are not satisfied, they may then appeal to the House, which, under the Bill, is to have all its control reserved. The House will be deluged with printed statements, and probably with garbled extracts from the evidence. These considerations show that Mr. Campbell-Bannerman had at least some justification for the amendment he moved—namely, "That the subjects dealt with in private Bill legislation ought not to be committed for inquiry to a Committee until it has been shown that it is

Digitized by Google

impracticable to remedy the evils now complained of by amending the present system of inquiry by Parliament, and by extending the powers of municipal authorities in counties and burghs." He pointed out that the private Bill business which came before Parliament might be referred to two classes. First, there were the schemes and proposals of municipal authorities for the introduction of water, for gas works, for extension of harbours, for widening streets, or for any other municipal purpose for the benefit of health and convenience of citizens, but such measures constituted only a quarter of the mass of private business. The other three-fourths were made up of the ambitious proposals of the important railway and canal companies. It was a remarkable fact, he said, that the parties concerned in these three-fourths were satisfied with the present methods, and he was of opinion that the other cases need not come to Parliament at all, if we only had the courage to give local authorities power in the matter. Railway Bills came upon a totally different ground. They were promoted by wealthy companies in rivalry with each other. The large expenditure of money which was incurred for that purpose by the railway companies was chiefly a matter for the shareholders, although the public were more or less directly concerned. Mr. Campbell-Bannerman believed that the railway companies were satisfied in their minds that the expense of having an inquiry locally would be greater than the expense of having the inquiry in London—that the expense of taking expert witnesses down to Scotland would be greater than the expense of bringing ordinary witnesses up to London, and that, therefore, nothing would be gained.

The whole question is one involving many aspects, and, therefore, deserving of very careful consideration. No doubt many of our readers have had experience of the present arrangements, and we should be glad to have their opinions regarding them, and also suggestions for their improvement, or for alternative arrangements.

ELECTRICAL SECTION OF THE LONDON CHAMBER OF COMMERCE.

A MEETING of this section was held on the 26th inst., when several matters of considerable importance were discussed. Great dissatisfaction is felt in electric lighting circles at the action of the Board of Trade in the matter of what are known as the "telephone clauses" in Provisional Orders. The position, as we understand it, is this: In 1889 a clause was agreed upon by the telephone and electric light representatives, or was arrived at in Committee. In 1890, however, when the Birkenhead Bill was in Committee, a clause was put in, and notice was sent round to various solicitors and parliamentary agents interested that it would be adopted. The clause was fought in Committee, but what form it finally took in the Birkenhead order matters little. In December of last year the Board of Trade communicated to those concerned on both sides its intention of inserting a new clause, which has been asked for by neither the telephone nor the electric light companies. The question is of great consequence. First, as to existing telephones with "earth returns," it is generally conceded by the electric light companies that they should either render their mains innocuous, or they should provide the telephone companies with metal return wires at their own expense. The difficulty is, however, chiefly with future telephone circuits. The electric light companies may lay mains which interfere with no existing telephone circuits, and then new telephone circuits may be erected, which will be disturbed. The electric light companies argue that the telephone companies should protect themselves by using insulated returns for such circuits. The telephone companies reply, however, that that would mean altering their whole system as soon as any such new circuits were required, for their switch boards and connections are designed for earth returns, and cannot be adapted to insulated returns without considerable alteration and great expense. Moreover, in London, the Telephone Company has no statutory powers enabling it to pull up streets, and doubling the number of overhead wires would not be tolerated. It was proposed by Colonel Jackson that Mr. Morse, who is solicitor for several electric light companies—though he attended the meeting merely as a member—should meet Mr. Winterbotham, solicitor to the Telephone Company, and discuss the matter in conjunction with Colonel Jackson and Mr. Garcke.

A report from the Sub-Committee on Overhead Wires was read. The Electrical Section are trying to induce the Board of Trade to reconsider their rules relative to overhead wires, chiefly as regards suspension and insulation of the smaller sizes of leads. Electric light engineers consider the suspensions and insulation to be prohibitive as regards expense, and to be unnecessary. The Section resolved to print and circulate the report of the Sub-Committee.

More than half the agenda referred to difficulties with the Board of Trade, and there is a very strong feeling in this matter. The Electrical Section holds that questions of telephone clauses, electrical standards, and overhead wires are commercial matters which concern the electrical engineering trades. The Board of Trade, on the other hand, ignores, as far as possible, the existence of the Chamber of Commerce, and, when in doubt, has recourse to the Council of the Institution of Electrical Engineers instead. Undoubtedly this Institution contains among its members nearly all the leading electric light engineers in the country, and is therefore a thoroughly representative body, but the Council is not in any way representative, and really contains only a small percentage of men versed in such questions. Though the members of the Council do their best for their Institution, and have its interests at heart, they have, we believe, little idea how much they are at variance with the general body of the Institution. The Electrical Section, therefore, object very strongly to such questions being referred to the Council of the Institution. Whether the Board of Trade consults the Council of the Institution, a general committee of the Institution, a committee of the Chamber, or the engineers of one or two of the largest electric light companies is really of little or no importance. All that is required is that an even hand should be held between the public, whose safety must be secured, and the electrical industry, which should not be saddled with needless difficulties.

The next question considered was the electrical standards of the Board of Trade. The Electrical Section asked that makers and users of instruments should be represented. The Board of Trade replied that it would avail itself of the evidence of makers and users if needed, but they were not required on the Committee. Of course, a great deal depends on what the Committee is to settle. If it is to decide whether the standards are to be taken from particular resistance coils and from Clark cells, or by deposition of copper or silver, the matter is not one of very much commercial importance. It would be preferable, however, other things being equal, that methods should be employed which are convenient in commercial use. Above all, it is important that the Board of Trade or legal volt and ohm should not vary from day to day. That is of much more consequence than scientific accuracy of definition or exact agreement with the most accurate determination of the standards. Under the supervision of the technical adviser it is not likely that there will be any such inaccuracy, but it is most important that the public should feel absolute confidence in the work of the standardising laboratory. There is no difficulty in working with standard resistances, in conjunction with either Clark's cells or voltameters, to a much greater degree of accuracy than commercial instruments admit; but, in spite of the ease of working accurately, calibration of instruments has been treated as a sort of mystery, and each maker still thinks that he alone can work within 1 per cent. Dr. Fleming, to whose energy the standardising laboratory is chiefly due, is conspicuous by his absence from the Committee.

Two electrical exhibitions were proposed, but the feeling of the Section was strongly against further exhibitions just now. With the Frankfort Exhibition and another at Chicago afterwards, and the Edinburgh display just over, electrical engineers, we think, feel that they have had enough of exhibitions for the present.

THE PROPOSED INDIARUBBER "RING."

WE agree with a daily contemporary that there is no great danger of an indiarubber "ring" for some time to come. We can quite understand the excitement in certain minds over the enormous consumption of rubber in different branches of engineering and manufacturing, as compared with the supply of the new material. But things are not as they were in 1883, when the price of Para rubber was 50 per cent. over that of the following year. The demand for rubber goods may be greater now than heretofore, but then more has been done towards getting the raw material, and it turns out that, instead of being restricted to any definite area, it is inclined to show itself in all directions, especially in such regions as Columbia and the vast forest of the Aruwhimi. The new Columbian railway through the valley of the Cauca towards Darien is said to tap a country containing extensive supplies of the Central American species (*Castilloa elastica*). Moreover, French and Italian travellers say that in the east of Columbia, towards the watersheds of the Orinoco and the Amazon, there is an abundance, not only of "Castilloas," but of "Heveas" also.

We shall await with interest a report on the quality of the rubber from the newly discovered forests, though we may take it for granted that it will not equal that at present obtained from Para and cured by the smoking process. But if it should so happen that some acute chemist finds out a method of so improving the quality of the African rubber, which is cheap enough, so as to enable it to be mixed with the best Para, with the result of lowering the cost of the latter, we should think that any syndicate would come to look upon the progress of things with an unfriendly eye. With reference to new sources of supply, it is satisfactory to hear that under the governorship of Sir Alfred Moloney, Lagos exported in 1885 rubber to the value of £70,000, although the trade was only commenced in a very small way five years before. Mr. Alvar Millson, Acting Commissioner at Badagry, has been very prominent in connection with new sources of rubber supply in the West Coast colonies, and we would refer those interested to his papers in the Kew Reports. If we are rightly informed, the rubber yielded by the Liberian forests, in the working of which Englishmen are interested, is of a quality quite equal to that of Para. Although this is a somewhat startling statement, it gives ground for hope that other sources of supply, together with the possibility of improvements in our manufacturing processes, may save the necessity of depending so much on the expensive productions made from the best Para rubber.

REVISION OF THE ORDNANCE SURVEY.

THERE are few things of so much importance to the country as a good set of thoroughly trustworthy maps of the different districts, and on the whole the people of Great Britain have been well served by the maps of the Ordnance Survey. It is rather a curious fact that in proportion to the area of which Government maps are procurable, the demand for them has not increased. This subject was discussed at the last meeting of the British Association, being introduced by Mr. Henry T. Crook, C.E., and several suggestions were made, but, so far as we are aware, the matter has been allowed to drop. As, however, it is one which is of considerable importance, in relation especially to industry and engineering, it is well that we should direct the attention of our readers to some of the points which were raised, so that steps may be taken for having them pressed home on the authorities.

The first reason given for the apparent want of appreciation by the public of the maps of the Ordnance Survey was that they were not accessible, and therefore not known, but on the whole we think that there is not much in this, as the arrangements for their supply are now fairly good. We attach more importance to the opinion that the maps do not meet popular requirements, and are, therefore, not in demand. Mr. Crook gave the following reasons why, in his opinion, the maps fail in many cases to meet the requirements of the classes of users for which they are presumably designed, viz.:—(1) Age. For want of revision large portions of even the 25in., but more particularly the 6in. and 1in. maps, are very incorrect, and in many cases quite obsolete. (2) Bad impressions or impressions from old and worn-out plates. (3) Complexity (in the 1in. map) through overcrowding of detail, causing confusion, the map being printed in only one colour. (4) Deficiency in information as to ground forms, particularly in the 6in. map (excepting Lancashire and Yorkshire). (5) Want of uniformity. (6) High price, especially in the case of the 6in., quarter sheets, and on all scales where sheets are partially blank. (7) Lack of explanatory information with the maps. Each of these points was discussed in detail. The Director-General of the Ordnance Survey admitted that he was quite sensible of a pressing need for a revision of the maps, but he pointed out that the question is really one of money, which it is for Parliament, and not for the Department, to decide. The extension of the 25in. survey has been so much pushed forward at the expense of revision that in many places revision must now be virtually a re-survey, as, in consequence of the length of time which has taken place since the maps were made, and the neglect to provide for a timely revision, the great part of them are obsolete and of little more than historical interest. The other points which have been mentioned as requiring attention are matters of minor importance, and are capable of comparatively easy

Digitized by Google

arrangement, but we would urge that the work of revision be at once commenced, and pushed forward with vigour, so that the maps may be of the greatest possible use to the public, for, without exactness, they may be very misleading. We may state that we refer to the matter simply for the purpose of increasing the efficiency of a Department which has done most valuable work for the advancement of geodetical and astronomical science.

Letters to the Editor.

OUR BIG GUNS, AND HOW THEY ARE MADE.

To the Editor of "Industries."

Sir,—Your correspondent, "C.E.," appears to be a little mixed. Rodman, the inventor of the Rodman gun, could not have heard of the name of Siemens at the time of the war between the Confederates and Federates. "C.E." would appear to be more intent on advertising the name of Siemens than in adding information on the subject.

Yours, &c.,
Yankee.

Liverpool, 21st January, 1891.

GAS AND ELECTRICITY.

To the Editor of "Industries."

Sir,—If, as sometimes happens, anything goes wrong with a central electric light station, and consumers are left in the dark, the fact is heralded all over the country, and the gas journals rejoice, and say, "We told you how it would be with this new-fangled invention." When, however, a gas company does the same thing, silence reigns supreme. The dailies take a special delight in alternately giving absurd puffs to electrical inventions and horrifying their readers with imaginary deaths of telegraph linesmen from touching live wires, but not one of them, as far as I have seen, has condescended to mention that last week the north of London, or at any rate a large part of it, was plunged into darkness by the Gas Light and Coke Company. The incident took place about eleven at night, and as at this hour some people are asleep in bed with their gas burners slightly on, far more serious danger was run than would be the case from a temporary extinction of glow lamps.

It is as well that publicity should be given to this fact, for though two blacks do not make a white, still there is no reason why gas companies should not have their blunders exposed as well as electric light purveyors.

Yours, &c.,
R.

Stoke Newington, London, N., 24th January, 1891.

THE SCOTTISH RAILWAY STRIKE.

To the Editor of "Industries."

Sir,—The debate in Parliament bodes no good for the companies, so far as their present attitude is concerned. It evidently foreshadows some legislation in the direction of restricting the hours of labour on railways. The perfectly obstinate attitude of the North British Railway Company in declining to submit to arbitration, in absolutely rejecting all efforts at compromise, in refusing even to say in the vaguest way that administrative reforms would be undertaken to avoid real cause for discontent among its servants and excessive inconvenience to the travelling public, is bound to recoil, not only upon its own head, but upon the whole railway service of the country. Comparison between the returns of the North British Railway as regards the hours of its servants with those of the other Scottish and any of the English lines reveals a state of matters quite sufficiently serious to account for the deplorable situation in which it finds itself.

The conduct of the company throughout this crisis has shown indeed that, while labour combinations may often exercise their power in a rash, selfish, and tyrannical way, a company employing 10,000 or 12,000 men, and controlling nearly half the railway system of Scotland, can put itself in flagrant opposition to the public interest in such a way as to make objections to direct legislation, and, perhaps, even oppressive legislation, almost certain to be unavailing. When a principle is strained to breaking point, as the North British Company has strained the principle that "a man may do what he likes with his own," the swing of the pendulum in the opposite direction is often extreme.

Railway shareholders may have little reason to congratulate themselves upon the battle the North British has been presumed to be fighting for them when they find the railways infested by inspectors to see that a driver does not work more than ten hours or that a signalman has not fallen asleep in his cabin. The people who really cause great, hurried, and sometimes disastrous changes are those who, like the authorities of the North British Railway Company, do not carry on the administration of the large interests with which they have been entrusted with a reasonable amount of tact.

Yours, &c.,
Disappointed Laisser-faire.

Glasgow, 28th January, 1891.

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—In reply to the critical letters of your two correspondents, I must preface my reply by an acknowledgement of the courtesy of the one writing over the *nom de plume* of "Cockney," whose communication I will first attempt to answer.

He observes that in all fairness I should have added, to the estimate of cost of the project, the cost of converting, in each house, the existing hearths for gaseous fuel firing. Now I think a little consideration will convince your correspondent that such an estimate, although possible in an approximate degree, is unnecessary. When a gas supply company is floated, it does not include in its capital the cost of supplying complete, or even connecting, services for every house within its lighting area, and the same may be said of electric lighting companies. The service mains are laid all through the district, and the property owners or occupiers must do the rest. There would be no hesitation on the part of the property owners, or even occupiers, once a cheap heating or fuel gas was supplied. They would be ready to convert the hearths for the use of the new fuel, as the change would enhance the value and attractiveness of their property, and if it cost them £5 to effect the alteration there would, I think, be no difficulty in obtaining an extra 7s. 6d. a year rent. This would pay 7½ per cent. on the outlay, and thus be a safe, and profitable, and advisable investment in every way.

For the poorer districts, the project, if carried out, would prove an incalculable blessing, especially if the new 1d. prepayment gas meters were installed along with the fuel gas service. This new prepayment system is certain to become most popular with the less favoured portion of the population, and I believe already that some gas companies will undertake, without any cost to the occupier, and on certain conditions, to provide prepayment meters. The extra difference over the ordinary price charged for the gas (measured by the volume delivered for one penny) pays them to do so. The system also conduces to economy in the use of fuel.

For the poor, one penny dropped into a slot will enable them to obtain sufficient heat for their purpose, and they can economise it to the most extreme limit. It is not so at present; wood has to be bought, and also coal or coke, costing, say, at least 6d., before a single thermic degree can be obtained. And what a wasteful system it is! A few hours of flickering and smoky flame, a few cheery sparks, an ashy grate, and the fire goes out, leaving the surrounding misery in deeper misery than before.

If we estimate the number of houses within the metropolitan area (I am writing from memory) to equal 450,000, and further estimate the average cost of converting each house at £5, this would, therefore, equal a total cost of £2,250,000, an outlay that would be readily borne and hardly be felt (in its minute division) by the property owners of London. That eminent sanitarian, Mr. Chadwick, estimated the annual damage done to London property by smoke to be equal to £2,000,000 sterling, so that about one year's saving in damage would counterbalance the cost of the household services and internal alterations for gas firing.

Respecting the stated difficulty of obtaining satisfactory arrangements and appliances for fuel gas burning, I believe there are now a good many cheap and effective gas heating and cooking appliances in the market, which are practically all that could be desired. What the householder generally complains of is the inadequate pressure and supply of gas, and that the *price* is too high. Remove these two impediments, and I don't think that the modern methods would leave much margin for improvement.

I terminate my remarks on your correspondent's letter by thanking him for the friendly tone of the last paragraph, which if echoed by his co-citizens would enable the project within a comparatively short and measurable period to become an accomplished fact.

Your correspondent "R. S." does not, I think, act justly in blaming me for ignoring the steps that are being taken by others towards the achievement of a similar object—namely, the prevention of smoke. The Committee in Manchester deserve every possible encouragement in their laudable work, and with steady persistence they will, I am sure, succeed in reducing, if not in removing, the evil in Lancashire and Yorkshire. They have a wide and difficult field for their operations in Manchester alone, and I do not know that the project I have described in any way clashes with their remedial proposals.

I thank "R. S." for the practical illustration he gives of the advantages of the employment of fuel gas at the works of Messrs. Brunner, Mond, & Co. It is striking evidence that for manufacturing purposes gaseous fuel may be utilised with economy, besides its evident collateral advantages to our agriculturists and to the hygienic condition of the workpeople.

The suggestion of "R. S." that the lower basements of houses should be made the *locale* of heat generation or combustion of the fuel gas, for distributing heated air to the upper floors, deserves consideration, and is a rational and scientific proposal; but I fear that we shall not readily overcome the insular prejudices of Englishmen in favour of the open and cheery fire, whether of coal or gas.

I cannot, in the contracted space of a letter, describe in detail the appliances that one could recommend for using the fuel gas—for cooking, heating, and for motor purposes; but without mentioning the proved appliances in use in Pennsylvania for natural fuel gas, there are a number of admirable contrivances which have been developed by British manufacturers that leave little to be desired in the way of efficiency and cheapness of first cost. It would be unfair to specify one more than another.

I feel certain, after reading the body of the letter of "R. S.," that he has no serious intention of damning the project with faint praise. He says: "This experiment at Brunner Mond's, together with the employment of natural gas at Pittsburgh, does certainly tend to support the views he has set forth."

Yours, &c.,
B. H. Thwaite.

Liverpool, 26th January, 1891.

To the Editor of "Industries."

Sir,—Every Londoner must wish that some such scheme as that proposed by Mr. Thwaite may soon be realised.

While agreeing with Mr. Thwaite generally, may I be allowed to suggest that his estimate of the future demand for illuminating gas is excessive? Surely it would be much better to do away with hydrocarbon gas as an illuminator altogether, and use the same gas for fuel and lighting, with only one system of pipes. Of course, incandescent burners would have to be used.

A very small reduction of the price of gas would make a great difference in the proportion of gas heating. At present gas stoves are too expensive; moreover, they are not well designed. They are generally fitted with asbestos radiators, which are white, whereas some black substance should be used. Moreover, they cause such a draught that nearly all the hot air produced by them is drawn up the chimney.

Judging by the slow progress of the electric light fraternity, London will have to depend on gas as an illuminant for many a long day, and now that the chief gas engine patent is run out, we will, no doubt, soon have numbers of cheap little engines which can be used for lifts and small power work.

If we had half the push of our American cousins, Mr. Thwaite's scheme would be taken up at once. I beg to enclose my card, and remain

Yours, &c.,
Londoner.

London, 27th January, 1891.

CYANIDE OF POTASSIUM AS A SOLVENT OF GOLD AND SILVER.

To the Editor of "Industries."

Sir,—Chlorine, which was thought to be the best and the most powerful solvent of gold, is considered now as having been superseded by cyanide of potassium, the affinity of which for gold has been discovered, we are told, after three years of researches and experiments, by Messrs. MacArthur and Forrest.

But, is there any discovery in these properties of cyanide of potassium for dissolving gold and silver? Is it a new thing to chemists, metallurgists, and electricians that cyanide of potassium dissolves gold?

As an electrician, I will only make two quotations about the dissolution of gold in a cyanide of potassium solution. I extract the first one from Elkington's specification, No. 8447 of 1840, page 6, l. 24:—

"The third part of our invention, which consists, it has been said, in coating, covering, or plating certain metals with gold by the use of a *solution of gold* in connection with the galvanic current, we perform as follows:—We take oxide of gold, prepared by any of the known methods, or *metallic gold in fine division*, and dissolve the same in a solution of prussiate of potash or soda. To about 2oz. of gold converted into oxide we add 2lb. of prussiate of potash dissolved in 1 gallon of water, and boil the same for about half an hour, and the solution is then ready for use. We prefer to keep the solution as nearly saturated with gold as possible, and for this purpose we keep a portion of oxide or of metallic gold in the solution undissolved. . . . We claim, therefore, the method of coating, covering, or plating the metals above mentioned with gold by the use—first, of an oxide of gold or *metallic gold* in fine division dissolved in prussiate of potash, or any soluble prussiate; and also by the use of *oxide of gold dissolved* in any other analogous salt."

I take from the paper of Messrs. Glassford and Napier my second quotation on the solubility of metallic gold in an aqueous cyanide of potassium solution. It is entited "Cyanide of Gold and Potassium" (*Phil. Mag.*, T. XXV., page 64; July, 1814.):—

"The following process, which we have employed, is *beautifully calculated for obtaining a large quantity of salt* in a few hours and at comparatively little trouble. A solution of cyanide of potassium is prepared, which contains about six times as much cyanide as the quantity of gold to be dissolved. The cyanide may be dissolved in twice, thrice, or four times its weight of distilled water, and carefully filtrated to separate any insoluble matters with which the cyanide is continually contaminated. This solution is then to be gently and carefully raised to the temperature of 100° F. in an earthenware or glass vessel. *Two plates of gold are placed in the solution at the opposite sides of the vessel*, and these are connected by means of copper wires to the poles of a small galvanic battery, composed of two or three pairs of zinc and copper plates and excited with dilute acid. As soon as the circuit is completed the operation commences, *gold is dissolved* from that plate connected with the copper end of the battery, *passes into the solution, and is only partly deposited* upon the opposite plate, while a gentle flow of gas is evolved from the negative plate. *The solution of cyanide of potassium* rapidly consumes the gold, which is *dissolved* at the positive pole, and becomes a *double salt of cyanide of gold and potassium*. The gold which deposits upon the negative plate is in minute grains, occasionally quite *brown*, is beautifully crystalline. The operation is much facilitated by having the positive plate or pole of gold several times larger than the opposite plate. At first the amount of gold deposited is very small compared with that dissolved from the positive pole, the solution retaining the greater proportion, but after some hours, as the solution becomes saturated, the amount deposited increases until there is a perfect balance. In this way ½oz. of gold may be dissolved in a few hours, and nearly 1oz. of the salt obtained."

As a chemist, I would say that in Thompson's "Chemistry," translated into French by J. Riffault, in 1807, prussiate of potash was stated to be the alkaline solvent of gold and silver. I would also refer to the paper by Proust, on "Facts for the History of Prussiates" (1806, Tome LX., pp. 225–249, *Annales de Chimie et de Physique*), which I quote as follows:—

"There are some metals which form simple and triple-prussiate, such as copper, manganese, cobalt, nickels, &c., some others forming only a simple prussiate: for instance, gold, &c."

There are also many other books from which I could extract passages, showing that the affinity of cyanide of potassium for gold has long been known. I will only give you a few names:—Liebig, Himly, Elssner, Prince Bagration, Gmelin, Hahn, Sagg, Wurtz, Lossen, and Birnbaum, &c. Hagen in 1805 (Hagen's "Untersuchungen," Vol. I., p. 655), states in a most emphatic manner that gold does not only dissolve in *aqua regia* or free chlorine, but also in a cyanide of potassium solution. Wahl, in his "Practical Guide for the Gold and Silver Electroplater," Philadelphia, 1883, makes the following statement:—

"It is a phenomenon worthy of remark that the solutions of cyanides even without the action of the electric current rapidly dissolve in the cold, or at a moderate temperature, all the metals except platinum, and that at the boiling point, they have scarcely any action upon the metals."

As a metallurgist, I would say that in a paper read before the Royal Society of New South Wales, August 1st, 1887, by W. E. Dixon, F.G.S., on a method of extracting gold and silver from pyrites, he states that the only salts of gold, besides chlorine, which possess sufficient stability, are bromide of gold (which was used by Figaguière before other patentees), and the auri-cyanides of the alkali metals, and he enters into details with regard to the action of cyanide. He also adds: "A patent was applied for in America in 1868 for the extraction of gold from its ores by cyanide, but I have no particulars of the process. It seems to me, however, that the high price of the salt, its insta-

Digitized by Google

bility when exposed to the air and in solution, and its extremely poisonous properties, precluded its use for this purpose."

To these objections, Janin, who had made in 1886 some experiments on the treatment of rebellious argentiferous ores at the Ontario Silver Mine, Utah, gave his views, and it will be interesting to give an extract from his paper on the subject in the *Engineering and Mining Journal*, 29th December, 1888, page 548, in which he says:—"According to Smee, the auri-cyanide of potassium may be easily made by simply placing a piece of pure gold in a solution of cyanide of potassium, but this is a long process. I found that gold leaf is readily soluble in a moderately strong solution. . . . . Cyanide extracts a large percentage of gold from raw and roasted pyrites, and from gold ores where the gold is present in a very finely divided state. But on raw ores the effect is less pronounced than on roasted ores, and therefore the drawback of the great solvent power of cyanide on base metals has very little importance."

Already, in 1867, the powerful dissolving properties of cyanide were patented in America by Dr. Rae (No. 61826), and in his specification he claimed the combined action of a current of electricity and of a suitable liquid such as cyanide, so that, by the action of cyanogen, the metal is reduced, and then can be collected. In 1880 Clark (No. 229586) patented the use of 1lb. of prussiate of potash, 1lb. of alkali, and 5lb. of salt to treat 1 ton of auriferous ores containing 5 per cent. sulphurets, and, as far as I can remember, he said in his claims: "The ore is completely desulphurised and the precious metals are freed." A little after, Faucett (No. 236424 of 1881) patented the use of cyanide of potassium with some other chemicals; he also employed a tumbler, and what he claimed was the separating of metals from refractory ores in subjecting the ores to the action of disintegrating chemicals. Then we find the specification of Sanders (No. 244080 of 1881), which is of minor importance, but in which we see that he employs cyanide, apparently for dissolving the coatings of the auriferous ores, but really to dissolve the gold. Simpson (No. 323222 of 1885) is more explicit; he uses cyanide of potassium with an addition of carbonate of ammonia, and precipitates the gold from the solution by means of zinc.

Where is the difference between Messrs. MacArthur & Forrest's process, patented in 1887, and Mr. Simpson's system, patented in 1885? The only one I find is that, in order to precipitate gold from the solution, Messrs. MacArthur & Forrest employ zinc in a state of fine division, which is neither efficient nor new, since the precipitation of gold by means of zinc in state of fine division was the object of the Price patent, No. 5125 of 1883. I think I have made one point clear—namely, that cyanide of potassium is common property.

Now the next question is: How to apply this solvent of gold? and, when the gold is in solution, how to separate it and how to catch it? It is a very long and tedious work to have to dissolve gold and exhaust its ores; and then, to have to filter the gold solution and to precipitate the precious metal by complicated and not altogether cheap methods, such as the alloy of zinc and sodium, suggested by Mr. Claude Vautin. I have no intention whatever of disparaging this mode of separation of gold any more than I would criticise the use of charcoal, through which Mr. Claude Vautin used to filter and separate the gold. But I confess I do not see the advantages of an alloy of zinc and sodium, while I see in this process many drawbacks which render it prohibitive.

What is wanted in any process for the extraction of gold from its ore, is not only novelty and patentability, but also efficiency, practicability, simplicity, and cheapness. As long as the gold and silver are not dissolved and separated *in one single operation*, the problem of the extraction of the precious metals will not be solved; and my experience in treating refractory or non-refractory auriferous ores is, that there is *nothing like the electric current* to exhaust the ore and to deposit the gold and silver it contains.

Yours, &c.,
E. ANDREOLI.

62, Loughborough Park, London, S.W.,
26th January, 1891.

Legal Proceedings.

PINTO *v.* TROTT.

THE SAME *v.* BADMAN.

THESE two actions were tried in the Queen's Bench Division, before Mr. Justice Day and a special jury. Mr. Aston, Q.C., and Mr. McCall appeared for the plaintiff; Mr. Lane, Q.C., with Mr. Willis Bund and Mr Herbert Reid, for the defendants.

The actions were brought to recover damages and obtain an injunction in respect of the infringement of the plaintiff's trade mark. The plaintiff is a manufacturer and importer of Mexican cigars, which he sells under a registered trade mark and the name "El Destino." The defendant Trott is a cigar merchant, and sells a brand of cigars known as "El Devino." The use of this name and of a label strongly resembling the plaintiff's in design constituted the acts complained of. The plaintiff, beside relying on the obvious resemblances between the two names and labels, called in evidence the designer who had prepared the defendant's label, and who deposed to having been furnished with a specimen of the "El Destino" label which he had copied. During the progress of the case, the jury conveyed an intimation of opinion to the judge, by whom it was communicated to counsel, and, in consequence, the counsel for the defendant did not argue the point as to imitation, but was content to discuss before the jury the question of the amount of the damages to be awarded, and to submit to the Court that the plaintiff had not successfully made out his title to the exclusive use of the trade name said to be infringed. For this purpose he relied on an alleged defect in the instrument under which the plaintiff had acquired the rights of Marcia Brothers & Co.—the original manufacturers of "El Destino" cigars—and on the fact that the name "El Destino" had been previously used by other manufacturers, and so used, as he alleged, as to have become matter of public right, incapable of being afterwards monopolised by any person. It is necessary for this purpose to prove user by three persons, and the user proved by the defendant in this case was a continuous user in the course of a business carried on at first by a firm of which the members were a father and his two sons; after the father's retirement, the two sons in copartnership; and, after the retirement of one of the sons, the other son trading alone. There was a further objection to the registration—that the name was a geographical name, and, as such, a descriptive word when applied to these goods. Mr. Justice Day overruled these objections, and, upon the finding of the jury in favour of the plaintiff, gave judgment for an injunction, damages and costs as asked.

The second action was brought in respect of another infringement by the use of the term "El Destinacion." The defendant in this case was a cigar dealer in Birmingham, in no way interested in the making of the cigars, which are of English manufacture. The case made against him was that his assistant had sold "El Destinacion" cigars for "El Destinos," and evidence was tendered in behalf of the plaintiff that a purchaser at one of his shops upon asking for "El Destino" had been offered cigars from a box labelled "El Destinacion" by an assistant, who held the box in such a way as to conceal with her finger the letters "cion" at the end of the word. This was denied by the incriminated assistant, but the jury, having regard no doubt to other matters—as the conduct of the defendant in taking up the quarrel instead of referring the plaintiff to the manufacturer who had supplied him with the goods, and to the fact that English manufactured goods were being passed off under a Spanish name, and that the label complained of was decorated with what appeared to be drawings of medals, although no prize medals had in fact been awarded to these cigars—found for the plaintiff in this case also, awarding damages to the extent of £50.

This latter case may at first sight appear to be one of some hardship, since the unfortunate retailer was certainly not primarily responsible for the infringement of the trade mark of which the plaintiff complained. It is, however, well that it should be generally known that a vendor of goods sold in derogation of trade-mark rights is equally responsible before the law with the person who commits the original act of piracy, and that the only safety for a person attacked by the owner of a trade mark lies in obtaining from some person who has a substantial interest to defend a sufficient indemnity against the consequences of an action, or a timely submission, which will reduce his damages to a nominal sum, or give him a substantial defence if the plaintiff refuses to acquiesce in a reasonable settlement of the dispute.

THE STANLEY SHOW.

THE fourteenth annual Exhibition of bicycles, tricycles, and accessories, which is being held at the Crystal Palace, and which closes on the 31st inst., differs somewhat from its predecessors from the fact that most of the principal cycle makers are conspicuous by their absence. The show, however, has suffered comparatively little from this, while the smaller makers, who are exhibiting in greater force than previously, are likely to reap a substantial reward. The number of machines exhibited is not quite so large as last year, but there are quite sufficient to satisfy the curiosity of the average spectator. The ruling features of the present Exhibition are undoubtedly the "pneumatic" and "cushion" tyres, by means of which racing cyclists were able last season to beat all previous records made with the old form of tyres.

If the relative numbers of the "safety" and "ordinary" bicycles exhibited may be regarded as any criterion, the latter type would seem to have almost become a thing of the past, except for racing purposes. It is interesting to note the rapid growth in public favour of the inflated tyres. At last year's show the principal novelty was the exhibit of the Pneumatic Tyre Company, whereas at the present Exhibition, owing to the enormous demand for these tyres, every exhibitor has a large proportion of the machines shown fitted with them. Another feature of the show is the absence of regard to mechanical principles. By purely empirical methods designs of superlative excellence have been gradually evolved—frames stiff and light, wheels admirably built, bearings little short of perfection, giving as a result machines through which can probably be transmitted a greater number of foot pounds of energy per pound weight than can be dealt with without injury by any piece of mechanism in any way comparable with them. But this has only been arrived at by the painful process of trial and error, and the adoption of such patterns as have proved successful in practice. Of the principles that are involved in the construction and propulsion of a cycle the average maker appears to know little or nothing, judging from the announcement, made in a catalogue, that the use of a band-brake acting on a drum attached to the hub of a steering wheel "solves the problem of a brake which shall not strain the spokes," the idea latent evidently being that the retarding force not being applied at the rim does not have to pass through the spokes.

A novel form of tyre is shown by the Maxim Company of Birmingham. This consists of a number of projecting studs of rubber placed very close together, instead of the continuous rim. The object of this is to prevent skidding of the wheel. The exhibit of Mr. Vaughan Sherrin, of 37, Tabernacle Street, E.C., is worthy of attention. This gentleman appears to have effectively studied the application of electric motors to cycles, and shows a tricycle so equipped which is capable of travelling at a speed of fifteen miles per hour, and also a Bath chair with a motor applied. Mr. W. E. Roberts, of Bristol, shows some new constructive features in connection with "safeties" for reducing vibration when a rider is passing over obstructions or uneven roads. He provides an oscillating lever or levers, fulcrumed at or upon the driving spindle or crank axle, and carrying at the end of it the axle of the rear or driving wheel, while the other or shorter arm of the lever is connected by means of a spring to the framework. In passing over a rough road the shocks to the back-wheel are thus reduced by the elastic properties of the lever. Mr. Harrison Carter, of London, exhibits a method of protecting and lubricating the pitch chain of safety bicycles and tricycles, which consists of a metal curve containing oil, through which the chain is made to travel. Mr. W. Bown, of Birmingham, exhibits a safety bicycle with a pneumatic tyre on the rear wheel only, the vibrations from the front wheel being absorbed by means of a spring fork. The Cornbrook Cycle Company and Acme Two Speed Gear Company exhibit safety bicycles fitted with their two-speed gear. This only adds about 2½lb. weight to the machine, and the apparatus is thrown in and out of gear by means of a small lever placed near the saddle.

The loan collection of curious and old machines is very interesting.

THE ELMORE COPPER DEPOSITING PROCESS.

THIS often-quoted process has taken practical shape at Leeds, and extensive works in connection with it are in course of construction. In the case of the Tube Making Company vats are already at work and orders are being executed, but the wire works are still incomplete. So much has, however, been done, that our representative paid a visit to the Leeds works on the 27th inst. to inspect the actual state of progress. Although the company was apparently unprepared for a special visit of the kind, much was seen of considerable interest. The most striking feature of the process is, perhaps, its automatic character, the depositing tanks being so arranged that work can go on day and night, the traverse of the burnisher being periodically altered in direction. We had hoped to give an illustrated description of the works at Leeds, but in consequence of the short notice that had been given of the visit adequate drawings and photographs could not be obtained in time. We hope to deal with them in a later issue.

Reviews.

THE METALLURGY OF STEEL. By Henry Marion Howe, A.M. (Harvard), S.B. Vol. I. New York: THE SCIENTIFIC PUBLISHING COMPANY. 1890.

This portly volume is the first instalment of a work which, although professing to be the outcome of a desire on the part of its publishers to give metallurgists an account of American steel works, fulfils a much larger design. The author practically gives an exhaustive account of all that has been done since the appearance of Percy's well-known manual, as he passes on to the various sections in the important departments of steel manufacture and the application of this material to industrial purposes. The term *steel* is used in its modern acceptation, and is made to include mild steel or ingot iron, as well as those alloys of the metal that are capable of being hardened and tempered. The intelligent observer of those mysterious actions to which cutting tools made of steel owe their main value will be pleased to find a well-founded theory that explains

Digitized by Google

them, even though we are told that it must be accepted as provisional. The chemical evidence adduced seems to prove conclusively that carbon exists in steel in two states of combination, being in one case called *hardening* carbon, because chiefly found in hardened steel, and in the other *cement* carbon, because chiefly found in cement or blister steel. One form readily passes into the other by changes of temperature. Thus the explanation is easily understood that "the heating which occurs in tempering and annealing relaxes chemical inertia so as to permit the carbon to pass from the hardening state, in which it has been previously imprisoned by sudden cooling, to the cement state, to a degree which, within limits, increases with the temperature reached."

The subject-matter of the book is treated on a methodical plan that must greatly facilitate the labour of reference, more especially to those who may consult the work on any of the many difficult questions bearing on the effect of the presence of various elements in the composition of steel. The chapters in the section that treats on these matters begin in each case with a summary containing the leading facts and conclusions, which are expanded in succeeding paragraphs, and the evidence for or against which is given in detail. In this way the effect of the various metals and metalloids that are usually met with in combination with steel is dealt with, not only from the point of view of the chemist, but also in their most intimate practical relations, so that the manufacturer has here a perfect storehouse of information. Some correspondence that appeared in the pages of *Industries* whilst the work under review was passing through the pages of our American contemporary, *The Engineering and Mining Journal*, is an evidence of the interest that this section of the work has already aroused. The representations made in the letters referred to might be understood to take Mr. Howe to task for the subordinate place he assigns to our knowledge of chemical composition as a means of indicating the physical properties of steel, but the same thing might be said in regard to his views as to the value of mechanical tests. The failures which Mr. Howe chronicles of material that had behaved admirably under test make it clear that there is still a mystery that lies beyond our present knowledge. The fact remains that a judicious combination of chemical and mechanical tests is absolutely indispensable to the manufacturer who wishes to conduct his processes with safety and efficiency.

The steel maker will turn with interest to the chapter on the prevention of "blow holes" and "pipes," a subject intimately connected with the phenomena of the absorption and escape of gases from iron treated of in the antecedent chapter. Various methods of liquid compression to effect the desired purpose have been adopted since Whitworth devised his mould for subjecting the ingots to hydraulic pressure, but none seem to have met with such success as that of S. T. Williams, who employs a mould one of whose inner faces is concave. As soon as the shell of the ingot has solidified, a plano-convex plate is slipped between mould and ingot, and the two sides of the mould are forced together by hydraulic pressure. Mr. Howe states that this process has been in use at Henry Disston & Sons' Tacony works for over two years, and he is informed that during this time not a saw has split on account of "piping." Fifteen presses are now in use, and twelve more are building.

The discovery of Regnard that the fresh fractures of ingots from certain heats of open-hearth steel emitted a sound of escaping gas, with an ammoniacal smell whose intensity seemed proportionate to the quantity of gas escaping, may have unforeseen consequences in regard to the much-sought-for synthesis of ammonia. As Percy only refers to the presence of ammonia in iron rust, the facts ascertained since his time, and brought together in Mr. Howe's work, should not be overlooked by those engaged in the investigation referred to. Chemists on the look-out for useful work to do will find other helpful suggestions in this book, such as the hint that the sulphuric acid, now wholly lost, in the calcination of the ferrous sulphate obtained as a by-product from the pickling liquor used in wire mills, might be recovered. The very interesting section on wire drawing may follow naturally after a discussion on "the rationale of the effects of cold working." So detailed an account, however, certainly comes as a surprise, even though the important and manifold uses to which wire is applied quite justify the introduction of a thoroughly practical description of the process that is sure to be appreciated by many readers. Billings' apparatus is also described, by which previously pickled steel and iron bars (round, square, hexagonal, &c.) are drawn cold through a die, by hydraulic means, to strengthen them, raise their elastic limit, and give them accurately uniform section. Although the division on cold working appears to be complete, we find no mention therein of Dyson and Hall's reeling process, which, although applicable only to round bars, admirably effects a similar purpose to that of Billings' and at less cost. The omission might have been intentional had the original scope of the work been carried out, as the process is a purely English one. In this case it is somewhat difficult to understand why Hadfield's recent labours on manganese steel, and those of Riley on nickel steel, should find so prominent a place in the appendix to this volume, seeing that Britain also must claim the honour of their discoveries, as must also be the case with the classical researches of Sorby on the microscopical structure of iron and steel which are incorporated in this work. In fairness to the author, we must add that he seems throughout most anxious to give credit where it is due, and that also, like Percy, he fearlessly gives expression to his opinions when they differ from the fashionable beliefs, thus greatly adding to the value of the work, which is illustrated with upwards of 200 engravings and diagrams and a like number of original tables. We shall welcome the advent of the next volume.

NOTES ON PERMANENT-WAY MATERIAL, PLATELAYING, AND POINTS AND CROSSINGS. By W. H. Cole, Executive Engineer, P.W.D. India. London: E. & F. N. SPON. 1890.

This little work is evidently written by one who has had practical experience of the matters with which he deals. In the preface the author dedicates his book to "the permanent-way inspector of to-day," "who," he says, "is not merely that vague product, a 'practical man'; he does not necessarily prefer guesswork to certainty; he has *not* a supreme contempt for a simple and intelligible mathematical method; . . . . and he is not one jot less practical than the platelayer of the old school, although he has had the advantage of a better education."

In the first chapter the nature and methods of manufacture of the materials used by the platelayer are first briefly described. The author then deals with the inspection and testing of steel rails, sleepers, fish-plates, and other parts of the permanent way; the construction and component parts of points and crossings; the relative merits of steel and wrought and cast iron, double-headed and other forms of rail, longitudinal and transverse sleepers and metal and wooden sleepers. On the subject of inspection of steel rails, &c., we think the author might with advantage have gone further into details and have described more minutely the character of the faults and flaws to be expected. We are also of opinion that detailed drawings of the forms of steel and pot sleepers most extensively used, and of a few standard rail sections and chairs, would add considerably to the value of the book. The author has, however, to a great extent disarmed criticism of this character by his remark in the preface, that "This little book has been written at scattered intervals of leisure," and that this may be pleaded "as a partial excuse for its unequal treatment of the subject and lack of completeness." Chapter II., on "Platelaying," is devoted to useful information of a distinctly practical character, including such matters as the distribution of workmen in platelaying, duties of permanent-way inspectors and sub-inspectors, "creep" or "travel" of rails, maintenance of wood sleepers, and treatment of metal sleepers. In Chapters III. and IV. the construction of points and crossings is explained, and the rules necessary for laying them out, together with various tables bearing upon the subject. This part of the work is well illustrated by diagrams, and very clearly yet concisely treated. In some cases more than one rule or method of determining certain dimensions is stated, as very frequently a simple approximate formula may with sufficient accuracy replace a mathematically exact but more elaborate expression. In any future edition we would suggest that a working drawing of a set of points and crossings should be added to the purely *diagrammatic* illustrations. Altogether, we are favourably impressed with Mr. Cole's work, and commend it to railway engineers.

STRUCTURAL MECHANICS: A HANDBOOK FOR ENGINEERS, ARCHITECTS, AND STUDENTS. By R. M. Parkinson, Assoc.M.I.C.E. London: GEORGE BELL & SONS. 1890.

This small book will be found very useful, as an intermediate step between treatises on theoretical mechanics and those which treat of applied mechanics or the different departments of engineering. It is evidently the outcome of the wants which the author experienced when he was a student, and, as such, is more likely to meet the difficulties of the majority of those for whom it is intended than if it had formed a systematic treatise. The author complains that such treatises do not take the student direct from the simpler to the more complicated problems which occur in practice. He treats the elementary and theoretical parts of the subject in as short a manner as possible, the chief part of the space being devoted to the solution of problems which can only be gathered from a number of different books, such as the works of Baker, Barlow, Box, and Twisden, and the papers by Bell, Christie, Clarke, and Fidler in the Proceedings of the Institution of Civil Engineers and the American Society of Civil Engineers. The author has freely consulted and used these works, and has selected his examples with reference chiefly to the everyday work of the engineer's and the architect's office, and for the purpose of comparing calculated results with actual experiments, a system which will impress the meaning of the different formulæ on the minds of the students. Like many books which treat of the properties of materials, there is sometimes a tendency to an inexact or double use of some of the terms employed. For instance, the word "strain" should be restricted to the deformations produced by the forces acting on a structure, and not to the accompanying stresses. We have suggested before now that a committee of the Institution of Civil Engineers should draw up an authoritative nomenclature for engineering subjects, in the same way as is being done by the British Association for physical subjects, and we now venture to repeat the suggestion, as almost every new book or paper shows that something of the sort is much wanted.

THE ENGLISH AND AMERICAN MECHANIC. By B. Frank Van Clive. New Edition. Edited by Emory Edwards, M.E. Philadelphia: HENRY CAREY BAIRD & Co. London: E. & F. N. SPON, 125, Strand. 1890.

This book contains within a comparatively small volume an immense amount of information, and is in fact, as its preface says, an Encyclopædia of Useful Technical Knowledge. It will be found useful, not only by the practical manufacturer and mechanic, but also by the amateur workman. It was stated in former editions of the work that it was intended to serve as a handy book of reference for the manufacturer, and to supply the intelligent workman with information required to conduct a process foreign, perhaps, to his habitual labour, but which at the time it might be necessary for him to practice. The new edition has been issued for the purpose of bringing the work up to date, and of otherwise improving it, in the hope that it may be still more useful in the future than it has been in the past. The editor, indeed, seems to have spared no effort at least to deserve success, and to have endeavoured to select only the best processes and recipes, which have been verified by competent authorities. With this end in view the European and American journals and transactions of societies devoted to technical subjects have been carefully searched.

The first part of the book is essentially a handbook for engineers, and contains many useful notes on the various departments of civil and mechanical engineering. We need not enter into any details of these, as they are very voluminous, but we may say that British engineers will find in them many useful hints regarding American practice which they would do well to study. The second part is made up of recipes of all kinds, which will be found most useful both in the actual workshop and by the amateur. Such subjects as alloys, solders, lacquers, varnishes, and cements receive particular attention, and the editor has, in addition, covered a very wide field of subjects. It would be difficult to name a subject in workshop practice on which useful and reliable information is not given. The book is rendered more complete, and its contents more available, by a very copious index, which makes reference to any subject or special recipe prompt and easy. We have no doubt that the success which this book has met with in America will, to a large extent, also attend it in this country, when its merits become more widely known.

THE ELECTRIC LIGHT. By John Urquhart. London: CROSBY LOCKWOOD & SONS. 1890.

This is the fourth edition of a comparatively old work, and is one of the few books on electric lighting extant in 1880, when the first edition appeared. Now it has a rapidly increasing number of competitors, but an attempt has been made to bring the work up to date. The author has not, however, been altogether successful in this. There are far too many descriptions of old and obsolete machines and lamps, and these occupy space that should be devoted to modern practice.

A TREATISE ON ELECTROMETALLURGY. By Walter G. McMillan. London: GRIFFIN & Co. 1890.

This is one of Messrs. Griffin's well-known "Scientific Textbooks." The title is somewhat too comprehensive, as the author deals but in a small way with the larger branches of electrometallurgy, such as copper refining. The work is really a treatise on electro-plating, and contains full and complete directions for depositing every useful metal and alloy. Several receipts are given for each solution, taken from a large number of authorities, so that the worker has a most extensive choice.

THE "EICKEMEYER" STREET RAILWAY MOTOR.

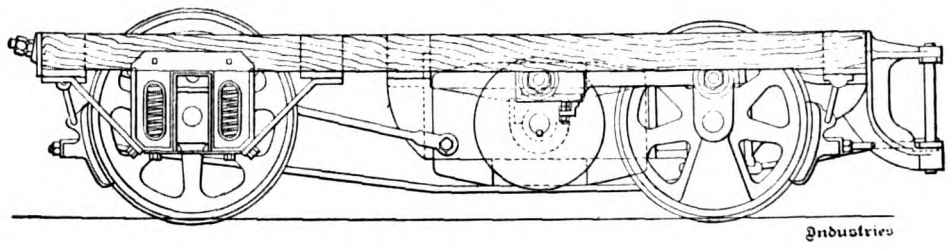

FIG. 1.—SIDE ELEVATION.

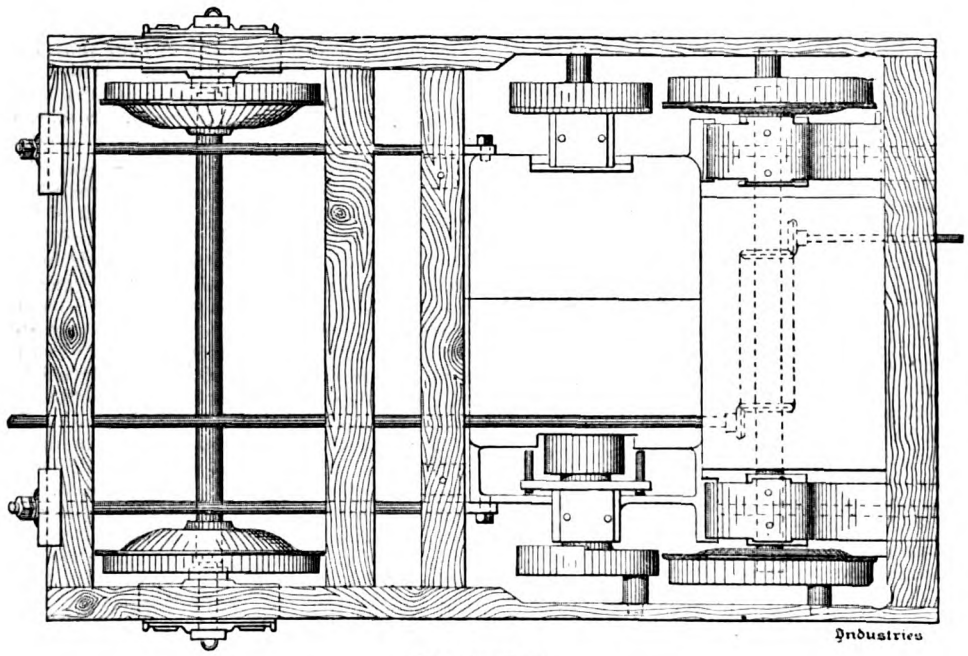

FIG. 2.—PLAN.

THE "EICKEMEYER" STREET RAILWAY MOTOR.

DURING the summer of 1887 Mr. Stephen D. Field worked an electric locomotive on the Thirty-Fourth Street branch of the elevated railroad of New York. The locomotive represented a new departure, the essential

FIG. 3.

feature of which lay in the fact that the machine was designed for a slow speed, and that the armature spindle was provided with a crank geared direct to the driving wheels by a connecting rod. The results obtained were so satisfactory that a street car was constructed on a similar principle, in which the well-known "Eickemeyer" motor was employed. The illustration Fig. 3 represents the car as it stands on the track. The motor is geared direct to the drivers, which are 18in. diameter, and is capable of developing 25 h.p. at 300 volts; it weighs altogether about 2,400lb. The armature is 12in. in diameter and 17½in. long. When the motor is running at a velocity of 150 revolutions per minute, the car attains a speed of 8½ miles an hour. We are informed that for ease of starting, evenness of running, and ability to get along sharp curves and gradients, the motor is very satisfactory. This system is about to be adopted at Lynchburg, Va. Figs. 1 and 2 show a side elevation and plan respectively of one of the trucks which will be employed there. The motor, which is designed to develop 35 h.p at 500 volts, will be geared directly to drivers of 26in. diameter by a 5in. crank, and under these conditions it is expected that a speed of 10 miles an hour will be attainable with only 120 revolutions per minute of the motor. The diameter of the armature is 13¾in., and its length 18½in. As in Mr. Eickemeyer's dynamos, these motors are all supplied with carbon brushes, but, unlike the usual type of solid blocks, a multiplicity of contacts is obtained by securing a series of carbon buttons to a spring plate, which presses them against the commutator and thus provides a number of contacts. We are indebted for our illustrations to the *Electrical Engineer* of New York.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.*

(*Continued from page* 89.)

Radiant Matter.—By means of this tube (Fig. 5) I am able to show that a stream of ultra-gaseous particles, or radiant matter, does not carry a current of electricity, but consists of a succession of negatively electrified molecules whose electrostatic repulsion overbalances their electromagnetic attraction, probably because their speed along the tube is less than the velocity of light. The tube has two negative terminals A A¹, close together at one end enabling me to send along the tube two parallel streams of radian matter, rendered visible by impinging them through holes in a mica diaphragm on a screen of phosphorescent substance. It is exhausted to a pressure of 0·1 mm. I connect one of the negative poles A with the induction coil, and the luminous stream darts along the tube from C to D parallel with the axis. I now connect the other negative pole, giving a second parallel stream of radiant matter. If these streams are in the nature of wires carrying a current they will attract each other, but if they are simply two streams of electrified molecules they will repel each

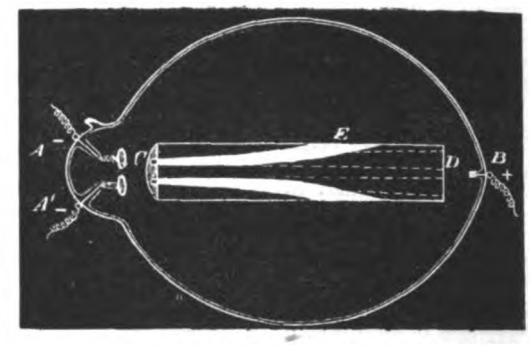

FIG. 5.—P = 0·1 MM.

other. As soon as the second stream is started you see the first stream jump away in the direction C E, showing strong repulsion, proving that they do not act like current carriers, but merely like similarly electrified bodies. It is, however, probable that were the velocity of the streams of molecules greater than that of light, they would behave differently and attract each other, like conductors carrying a current.

The Edison Effect.—An exactly parallel experiment has been made by Mr. Edison, Mr. Preece, F.R.S., and Professor Fleming, using, instead of a vacuum tube, an incandescent lamp. They found that from an idle pole placed between the ends of the filament the electricity always flowed as if the pole were the zinc element of a copper-zinc cell. Having repeated their experiments, I entirely corroborate them. I get a powerful current in one direction from an idle pole placed between the limbs of an incandescent carbon filament, and one in the opposite direction from an idle pole in a highly exhausted vacuum tube. This discrepancy was extremely puzzling, and I tested, with a similar result, very many experimental tubes made in different ways.

Some of the contradictory results are due to the exhaustion not being identical in all cases. In my vacuum tubes the directions of current between the idle pole and the earth changes from negative to positive as the exhaustion rises higher. Testing the current when exhaustion is proceeding, there is a point reached when the galvanometer deflection—hitherto negative—becomes nil, showing that the potential at this point is zero. At this stage the passage of a few more drops of mercury down the pump tube renders the current positive. This change occurs at a pressure of about 2 mm.

After this point is reached, when the induction current is passed through the tube, the walls rapidly become positively electrified, probably by the friction of the molecular stream against the glass, and this electrification extends over the surface of any object placed inside the tube.

Properties of Radiant Matter.—One of the most characteristic attributes of radiant matter—whence its name—is that it moves in approximately straight lines, and in a direction almost normal to the surface of the electrode. If we keep the induction current passing continuously through a vacuum tube in the same direction, we can imagine two ways in which the action proceeds; either the supply of gaseous molecules at the surface of the negative pole must run short, and the phenomena come to an end, or the molecules must find some means of getting back. I will show you an experiment which reveals the molecules in the very act of returning. Here is a tube (Fig. 6) exhausted to a pressure of 0·001 mm., or 1·3 M. In the middle of the tube is a thin glass diaphragm C, pierced with two holes D and E. At one part of the tube a concave pole A¹ is focussed on the upper hole D in the diagram. Behind the upper hole, and in front of the lower one, are movable vanes F and G, capable of rotation by the slightest current of gas through the holes.

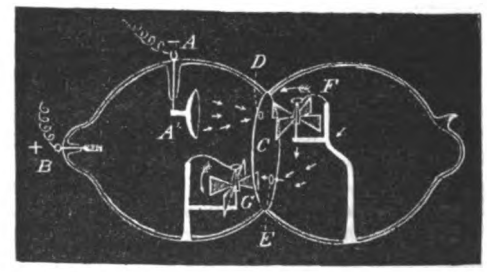

FIG. 6.—P = 0·001 MM.

On passing the current with the concave pole negative, the small vanes rotate in such a manner as to prove that at this high exhaustion a stream of molecules issues from the lower hole in the diaphragm, whilst at the same time a stream of freshly charged molecules is forced by the negative pole through the upper hole.

This view of the ultra-gaseous state of matter is advanced merely as a working hypothesis, which, in the present state of our knowledge, may be regarded as a necessary help, to be retained only so long as it proves useful. In experimental research early hypotheses have necessarily to be modified, or adjusted, or perhaps entirely abandoned, in deference to more accurate observations. Dumas said, truly, that hypotheses were like crutches, which we throw away when we are able to walk without them.

* Abstract of Presidential Address given by Mr. William Crookes, F.R.S., before the Institution of Electrical Engineers on the 15th inst.

Radiant Matter and "Radiant Electrode Matter."—In recording my investigations on the subject of radiant matter and the state of gaseous residues in high vacua under electrical strain, I must refer to certain attacks on the views I have propounded. Dr. Puluj's paper concerns me most, as the author has set himself vigorously to the task of opposing my conclusions. Dr. Puluj has no authority for linking my theory of a fourth state of matter with the highly-transcendental doctrine of four dimensional space. I could quote numerous passages from my writings to show that what I meant and said was the mean free path as amplified and modified by the electrification. In this view I am supported by Professor Schuster, who distinctly admits that the mean free path of an electrified molecule may differ from that of one in its ordinary state.

The greatest difference between Puluj and myself lies in his statement that "*the matter which fills the dark space consists of mechanically detached particles of the electrodes which are charged with statical negative electricity, and move progressively in a straight direction.*"

To these mechanically detached particles of the electrodes, "of different sizes, often large lumps," Puluj attributes all the phenomena of heat, force, and phosphorence that I from time to time have described in my several papers.

Puluj declares that the phenomena I have described in high vacua are produced by his irregularly shaped lumps of radiant electrode matter. My contention is that they are produced by radiant matter of the residual molecules of gas.

Some metals, when used for the negative electrode in a vacuum tube, volatilise more or less rapidly, coating any object in their neighbourhood with a very even film. Aluminium, however, seems exempt from this volatility. Hence, and for other reasons, it is generally used for electrodes.

If, then, the phenomena in a high vacuum are due to the "electrode matter," the more volatile the metal used the greater should be the effect.

Here is a tube, Fig. 7 (P = 0·00068 mm., or 0·9 M.), with two negative electrodes A A^1, so placed as to project two luminous spots on the phosphorescent glass of the tube. One electrode (A^1) is of pure silver, a volatile metal, the other (A) is of aluminium, practically non-volatile. A quantity of "electrode matter" will be shot off from the silver pole and practically none from the aluminium pole; but in each case the phosphorescence (C C^1) is identical. Had the radiant electrode matter been the active agent the more intense phosphorescence would proceed from the more volatile pole.

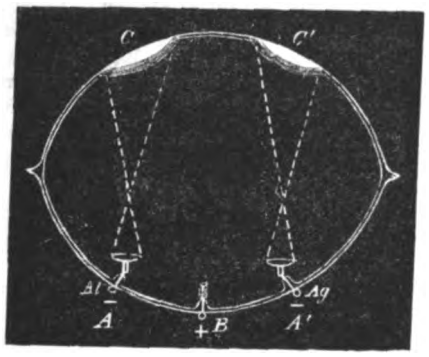

FIG. 7.—P = 0·00068 MM.

The identity of action of silver and aluminium in the first case, and the non-projection of silver in this second instance, in themselves are sufficient to condemn Dr. Puluj's hypothesis, since they prove that phosphorescence is independent of the material of the negative electrode. In front of me is a set of tubes that to my mind puts the matter wholly beyond doubt. The tubes contain no inside electrodes with the residual gaseous molecules, and with them I will proceed to give some of the most striking radiant matter experiments without any inner metallic poles at all.

In all these tubes the electrodes, which are of silver, are on the outside, the current acting through the body of the glass. The first tube contains gas only slightly rarefied and at the stratification stage. It is simply a closed glass cylinder, with a coat of silver deposited outside at each end, and exhausted to a pressure of 2 mm. The outline of the tube is shown in Fig. 8. I pass a current, and, as you see, the stratifications, though faint, are perfectly formed.

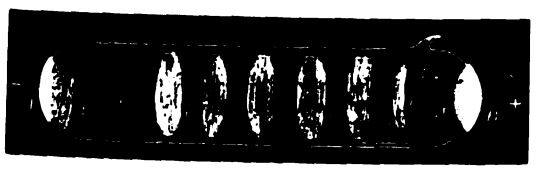

FIG. 8.—P = 2 MM.

The next stage, dealing with more rarefied matter, is that of phosphorescence. Here is an egg-shaped bulb, shown in Fig. 9, containing some pure yttria and a few rough rubies. The positive electrode B is on the bottom of the tube under the phosphorescent material, the negative A is on the upper part of the tube.

A shadow of an object inside a bulb can also be projected on to the opposite wall of the bulb by means of an outside pole.

Passing to the next phenomenon, I proceed to show the production of mechanical energy in a tube without internal poles. It is shown in Fig. 10 (P.=0·001 mm., or 1·3 M.). It contains a light wheel of aluminium, carrying vanes of transparent mica, the poles A B being in such a position outside that the molecular focus falls upon the vanes on one side only. The wheel rotates rapidly, reversing in direction as I reverse the current.

All the old "radiant matter" effects can be produced in tubes containing no metallic electrodes to volatilise. It may be suggested that the sides of the tube in contact with the outside poles become electrodes in this case, and that particles of the glass itself may be torn off and projected across and so produce the effects. This is a strong argument, which fortunately can be tested by experiment. In the case of this tube, Fig. 11 (P. = 0·00068 mm., or 0·9 M.), the bulb is made of lead glass phosphorescing blue under molecular bombardment. Inside the bulb, completely covering the part that would form the negative pole A, I have painted a substantial coat of yttria so as to interpose a layer of this earth between the glass and the inside of the tube. The negative and positive poles are silver discs on the outside of the bulb, A being the negative and B the positive pole. If, therefore, particles are torn off and projected across the tube to cause phosphorescence, these particles will not be particles of glass, but yttria, and the spot of phosphorescent light C on the opposite side of the bulb will not be the dull blue of lead glass, but the golden yellow of yttria. You see there is no such indication; the glass phosphoresces with its usual blue glow, and there is no evidence that a single particle of yttria is striking it.

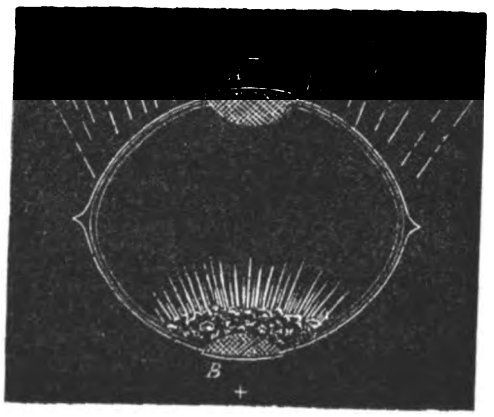

FIG. 9.—P = 0·00068 MM.

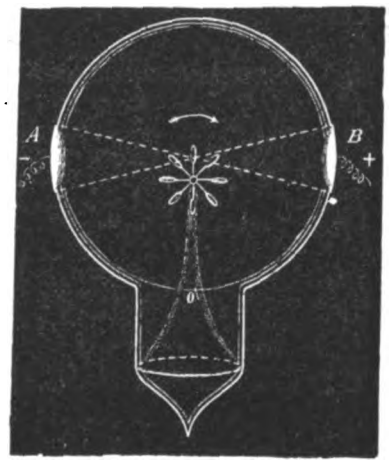

FIG. 10.—P = 0·001 MM.

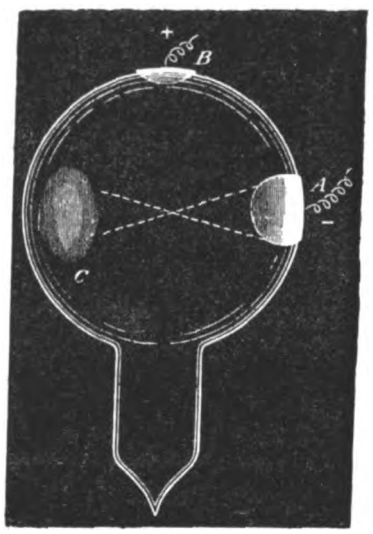

FIG. 11.—P = 0·00068 MM.

Witnessing these effects I think you will agree I am justified in adhering to my original theory that the phenomena are caused by the radiant matter of the residual gaseous molecules, and certainly not by the torn-off particles of the negative electrode.

(To be continued.)

ORGANIC ANTISEPTIC COMPOUNDS.

THE late Dr. Carnelly contributed to the Chemical Society, just before his death, the results of an investigation to determine the influence of atomic arrangement on the antiseptic properties of organic compounds. It is well known that within recent years many organic compounds have been proposed and are actually in use in antiseptic treatment, and as good preservatives and from an economical point of view, as well as of theoretical interest, it is important to ascertain what factors determine the antiseptic nature of the bodies referred to. Most of the physical properties of organic compounds have been shown to be determined by the orientation or relative position of the various elements or groups in the molecule, and there can be no doubt that the "germ-destroying" property will also bear some definite relation to the constitution of the compound. In Professor Carnelly's experiments sterilised peptogelatine, containing a known weight of the antiseptic, was inoculated by exposure in a dusty room for fifteen minutes, and, after the lapse of some days, the surface of the jelly was examined for growths or colonies of micro-organisms. By varying the amount of antiseptic it was quite easy to hit the point so that a milligram more or less of the substance was sufficient to reverse the result, and in this way it would be possible to arrive at what may be called the fatal dose, or limit of safety, in employing any given antiseptic as a food preservative. So far as the investigation has at present been conducted, it has been proved that among the di-derivatives of benzene, the *para*, or most symmetrical compounds, are usually more powerfully antiseptic than the corresponding *ortho* and *meta* compounds. The oxy-benzoic acids are, however, an important exception to this rule, the *ortho* acid (salicylic) being far more powerful in its action than its two isomers. The phenols and nitro-compounds appear to have a relatively high antiseptic power, so that among the above derivatives of benzene this property culminates in para-nitrophenol.

LUBRICATING OILS AND GREASES.

AT the meeting of the associates of the Insurance Institute of Manchester, held on the 14th inst., a paper on the above subject was read by the county analyst, Mr. J. Carter Bell, A.R.S.M. For the purpose of making the paper thoroughly practical Mr. Bell divided the subject into the following queries, which he then proceeded to answer, viz.:—(1) What are mineral oils made from? (2) With what are they mixed or blended for lubricants? (3) If not mixed, are they more dangerous than mixed or blended? (4) What are the flashing points of oils at present in use? (5) Are any "low flash" oils now used? (6) Will mineral oils on waste cause spontaneous combustion? If not, why? (7) State any danger of fire from "friction" in the use of these oils. (8) From what are lubricating greases made, and which kind are dangerous?

With regard to question (1) Mr. Bell stated that mineral oils are made from natural oil and shale. The natural oil is obtained from America and Baku (in Russia); the shale oil is obtained from the distillation of shale in Scotland. The Russian oil supply is increasing at an enormous rate, and in the future bids fair to supplant America and Scotland. Thus, in the first five months of 1890, Russia exported 828 million pounds, being an excess of 270 million pounds over the same period of 1889. (2) In the preparation of lubricants for textile machinery mineral oils are commonly blended in various proportions with animal oils, such as neatsfoot oil, lard oil, tallow oil, and occasionally sperm oil, and not unfrequently with olive oil. (3) As the "flashing points" of the leading animal and vegetable oils range from 100° to 150° Fahr. above those of ordinary mineral lubricating oils, and as the addition of any considerable percentage of fatty oil to mineral oil produces an oil having its flash point proportionately above that of the pure mineral oil, it seems reasonable to suppose that a well-blended oil is safer than a pure mineral oil, and not only on account of its greater power in reducing friction and in preventing increase in temperature, but on account of its higher flash point. (4) The flashing points of oils in use are on an average over 350° Fahr., and oils obtained from first-class manufacturers are from 360° to 370°, and therefore insurance companies should lay down a hard and fast rule that no lubricating oil should be used in any mill that has a lower flash point than 350° Fahr., and that lost more than 5 per cent. in twelve hours at 140° Fahr. The first-class oil manufacturers would be glad, he said, to hear that such was the decision of the Insurance Institute. (5) Very few low flash oils are now in use; from an examination of about 170 oils, only 14 per cent. flashed under 350° Fahr. (6) Mineral oils on waste will not

Digitized by Google

cause spontaneous combustion, because, being hydrocarbons, they are not liable to oxidation, and a mixture of mineral and animal oil is also not liable to spontaneous combustion, unless the animal oil is in very large excess, and even then the danger would be very small. (7) It is difficult, if not impossible, to establish any graduated ratio of danger in relation to the flashing points of oil, but it must be evident that in the event of a journal or bearing becoming heated to a temperature approaching that of the flashing points of ordinary lubricating oils, the lower the flashing point of the oil in use on that bearing, the sooner will it produce an atmosphere of inflammable and explosive gas ready to be ignited by any spark from the heated machinery, and to communicate flame to any material in the neighbourhood. (8) Lubricating greases should be made from mixtures of tallow and palm oil mixed with other oils, the flash points of which should be high. The most dangerous greases are those which are made from the refuse of coal tar products, such as anthracene oil, dead oils, creosote mixed with lime, steatite, plumbago, sulphur, &c. The grease which was in use at a cotton mill near Manchester, recently destroyed by fire, was made from tar oils and anthracene. This was highly inflammable, and the grease, when once fired, was not easily put out. Snch a compound should never be allowed to be used in any mill.

An interesting discussion followed the reading of this paper, and many important points were raised, which were fully answered by Mr. Bell, after which a vote of thanks was accorded him for his valuable paper.

THE "JUBILEE" OF THE CHEMICAL SOCIETY.

The Chemical Society of London is the eldest among chemical societies, and, having been founded in 1841, it is now in the fiftieth year of its existence. Arrangements have been made to celebrate this important occurrence in the history of the Society. The first meeting of the Society was held on February 23rd, 1841, in the house of the Society of Arts, John Street, Adelphi, and in the report of this meeting we find the well-known names of Andrews, Brande, Daniell, De La Rue, Fownes, Graham, Grove, Lyon Playfair, Stenhouse, Warington, and others among the list of original members. A provisional committee was appointed to draw up a report for the government of the Society, and at the second meeting this report was presented and adopted, and Professor T. Graham was elected the first President of the Society. On April 13th of the same year the Society commenced work by the reading of a paper "On the Preparation and Formation of Yellow Prussiate of Potash," by Professor Liebig. After publishing memoirs for a few years at irregular intervals, the council changed the publication of the Society to a quarterly journal, and finally this was supplanted by the present well-known journal of the Society issued monthly, which now not only publishes the transactions of the Society, but gives a monthly digest of foreign chemical literature. Within the last few years the Society has published proceedings as soon after the reading of papers as possible, containing an abstract or preliminary notice of the author's communications to the Society. The "Jubilee" celebrations include a meeting on February 24th, at 3 to 5 o'clock, at the Society of Arts, where the original meeting took place on February 23rd, 1841, at which the formation of the Society was decided on. At this meeting various addresses will be delivered, and delegates from other societies will be received. On the evening of the same day the President and Council will hold a reception at the Goldsmiths' Hall, which has been placed at the disposal of the Society for the purpose by the Worshipful Company of Goldsmiths. On the evening of February 25th the Fellows and their friends will dine together at the Hôtel Métropole.

Notes.

PERUVIAN RAILWAYS.

The new Verrugas Bridge on the Lima and Oroya Railway in Peru has recently been completed. This bridge replaces the famous viaduct over the Verrugas Gorge, which was built in 1871 by the Baltimore Bridge Company (illustrated in *Industries*, Vol. II., page 38), and destroyed by a flood in March, 1889. The new bridge will be secure against such an accident, inasmuch as there are no piers in the centre of the ravine which it crosses, the undermining of which was the cause of the failure of the old viaduct. The new bridge is of the cantilever type, 575ft. long, and is supported on two iron piers. The cantilever arms are each 235ft. long, and the suspended span is 105ft. At the centre it is 250ft. above the bottom of the valley. The new bridge was designed by Mr. L. L. Buck, M.Am.Soc.C.E., and was constructed by Messrs. Cooper, Hewitt, & Co., Trenton, N.J. The Oroya Railway has its present terminus at Chicla, eighty-seven miles from Callao, and 12,300ft. above the sea level. Arrangements are being made to complete the road from that point to the Cerro di Pasco Mines, and thence to a point on the upper waters of the Amazon.

ELECTRIC TRACTION.

It is reported by the London correspondent of the *Elektrotechnische Zeitschrift* that the Barking line of accumulator cars is being run at a heavy loss. The depreciation of the accumulators is stated to cost at least 2d. per car mile, and at the contract price of 4½d. per car mile the General Electric Power and Traction Company, Limited, are said to be losing 1d. per car mile. In the interests of electric traction in this country it would be well if this assertion were either confirmed or corrected.

FLEXIBLE MOULDINGS FOR ELECTRIC LIGHTING PURPOSES.

For ingenious practical contrivances we must generally turn to America. Mr. John A. Seely, of New York, has, according to our American contemporary, the *Electrical Engineer*, brought out a flexible moulding. The wires, already well insulated, are imbedded in a flexible insulating material, which is moulded so as to have the same appearance as the usual wooden cases. This moulding has the advantage, however, that it can be bent round corners if they are not too sharp.

SURFACE LEAKAGE IN ELECTRIC LIGHTING.

Now that electrical supply companies demand a very high standard of insulation before they will connect a house to their systems, the surface leakage question comes to the front. In many cases there will be as much leakage in one lamp holder exposed to the weather as a door light or gate light as in all the rest of the installation. All fittings exposed to vapour condensation from fogs and moist air should be made perfectly water-tight by some elastic packing, so that condensation cannot give rise to surface leakage.

VACUUM TUBES.

Mr. Crookes' presidential address to the Institution of Electrical Engineers was of unusual interest, owing to the large number of experiments shown. Engineers are a little apt to look upon vacuum tubes as of interest only from a purely research point of view. Is it unlikely, however, that the light of the future, which is to take little power and develop little heat, will be some sort of vacuum discharge? Vacuum tube lamps have already been used or proposed by Trouvé and others, but so far have not been successful.

RAILWAY CONSTRUCTION IN THE UNITED STATES IN 1890.

During the past year there were constructed in the United States 6,080 miles of railway, which is somewhat below the average of the previous ten years, although slightly greater than that of 1889. The Eastern States are pretty well supplied with railways, and therefore the greater part of the construction has taken place in the Southern, South-Western, and North-Western States. The latter has had the most rapid rate of growth, many important extensions having been made, the Great Northern having pushed its way nearly to the Rocky Mountains. With these exceptions, however, the greater part of last year's additions consist of branch and supplementary lines, rendered necessary by increased population and traffic.

NEW ZEALAND RAILWAY CARRIAGES.

The *N. Z. Railway Review* states that an improved railway carriage has been placed upon the Wellington-Taranaki line. Two sets of carriages, each comprising one first-class and one second-class vehicle, have just been turned out of the Petone Government workshops, and reserve sets are also being manufactured, and expected to be completed shortly. Each first-class carriage is mounted on a double-bogie frame. Exterior balcony runs along one side of the carriage for half its length, to enable passengers to indulge in a promenade, the danger of falling off being obviated by an iron railing and lattice-work. Abreast of this balcony there are three separate compartments, viz., a smoking recess luxuriously fitted up, a well-appointed lavatory, and a comfortable cushioned and padded section available by engagement by private parties. It is seated for six persons. The remaining half of the carriage is fitted along one side with reversible double cross seats, which are of the American pattern, but with wooden arm-rests. Along the other side there is a comfortable couch running longitudinally. Another important feature is that the two smaller compartments can be readily provided with beds for the accommodation of invalid passengers. The second-class carriages have been furnished with lavatories, and in other respects improved as compared with those used on other lines. New Zealand timber and other material have been used throughout in construction. These carriages were made at the Addington workshops, and mounted and decorated at the Petone shops under the superintendence of Mr. Beatty.

ELECTRICAL HEATERS.

In the United States quite a large business is done in electrical heaters. At first sight this method appears an expensive way of heating, but on further consideration this is seen to be hardly the case. A fire sends most of its heat up the chimney—that is to say, it has a very much lower efficiency than a central station. In addition to this, it causes dirt in the house, and cannot be turned on or off just when wanted. It is not likely that we will use electric stoves instead of fire, but electric heaters are so very much more convenient that they will probably come into very general use. For instance, if a person is writing, his feet often get cold, and it is almost impossible to arrange a fire to keep them warm, especially during such weather as has been experienced lately. An electric heater, taking about twenty watts, and costing less than a farthing an hour, will do. To boil a kettle containing a couple of pints of cold water needs, theoretically, 125 watt hours, or a penny-worth of energy. If the kettle is coated with felt, and is heated from the inside quickly, this amount of energy should be nearly enough. In 1885 Mr. J. S. Sellon exhibited electrical foot-warmers at the Inventions Exhibition, and since then various engineers, such as Messrs. Ferranti, Madgen, Gay, and Hall, have been working in the same direction. For such purposes as keeping sleeping children warm at night, of course nothing can compete with electric heaters. In the United States it is said that instead of hot-water tins vessels containing fused acetate of soda are used. The latent heat of fusion is great, so they keep at one temperature a long time. Even they can hardly compete with electrical heating when once introduced.

NEW GRAVING DOCK AT BOMBAY.

The new graving dock, which the shipping interests of the port of Bombay have so long demanded, is so far advanced that it is likely to be ready for use in the course of next month. The dimensions of the new dock are as follows:—Length of floor, 500ft.; extreme length available for docking purposes, 530ft.; width at coping, 90ft.; width at floor, 62ft.; depth of dock at head, 33ft.; depth of stern, 34ft.; available depth for docking at H.W.O.S.T., 27ft. 3in.; width of entrance, 65ft. 6in. The work is very substantial, states the *Indian Engineer*, no less than 140,000 cubic feet of dressed stone and 32,000 cubic yards of rubble masonry having been utilised in the construction. The dock will hold about 7,000,000 gallons of water, which will be filled through culverts placed on either side of the entrance, and with the three powerful 36in. centrifugal pumps, which have been supplied by Messrs. James Watt & Co., Birmingham, it will be possible to empty the dock within the space of three hours, which means that the pumps will have to deal with not less than 40,000 gallons per minute. It may here be stated that the caisson was built by Messrs. J. & G. Rennie, and put together in Bombay in the early part of last year. All, therefore, that now remains to finish the dock is the erection of the engine-house, and this is being pushed forward as speedily as possible. This portion of the work, which could not, for many reasons, be proceeded with while the other work was in progress, is now well in hand, and there is not the least doubt but that everything will be quite ready for the opening of the dock in the course of next month.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

12th January, 1891.

541. Hamilton, J. ..... Steam engine governors.
547. Fowler, A. B. ..... Buffing, sand papering, or heel scouring machines.
552. Burrell, F. J. ..... Pneumatic guns.
561. Briercliffe, J. R. G. ..... Speed regulators of motive power engines.
571. Halsey, T. P. C. ..... Jury shafts for propellers.
574. Riedinger, A. (of the Kommandit-gesellschaft für Popp'sche Druckluftanlagon, August Riedinger & Co.) ..... Engine governor.
578. Bourgoin & Decorce ..... Gas making apparatus.
579. Saville, A. ..... Boring machine and self-centreing chuck for same.

13th January, 1891.

603. Ineson, B. ..... Gear shaft for weaving purposes.
610. Cauthebley, H. ..... Motive power engines.
615. Allison, H. J. ..... Type-writing machines (*The Transatlantic Machine Company*).
619. Hutchison, R. ..... Jacquard machines.
624. American Elevator Company ..... Electrical elevator apparatus (*Otis Brothers & Co.*).
626. Anderson, R. W. ..... Sewing machines.
634. Kingston, Swallow, & Jeffrey ..... Railway chairs and wedges.
636. Jones, W. ..... Sewing machines.
637. Wells, C. ..... Steam engines.
640. Milnes & Elgar ..... Wire netting machine.
645. Greenamyer, C. V. ..... Wrenches and similar tools.
651. Newton, H. E. ..... Direct-acting duplex engines (*Worthington*).
670. Myers & Wells ..... Screw propellers.
672. Thompson, W. P. ..... Matrix-making machines (*Landsberg & Köhler*).
677. Imray, O. ..... Bolt heading machines (*Seaton & Seaton*).
682. McNeil, M. ..... Steam pressure gauges.

14th January, 1891.

694. Taylor, R., Jun. (of the Firm of Asa Lees & Co., Ld.) ..... Machines for opening and clearing cotton and other fibres.
695. Taylor, R., Jun. (of the Firm of Asa Lees & Co., Ld.) ..... Grinding the flats of carding engines.
696. Macqueen, J. ..... Spindles used in spinning or doubling fibrous materials.
708. Griffin, S. ..... Hydrocarbon motors.
710. Sheldon, J. ..... Differential pulley blocks.
719. Downing, G. C. ..... Lubricators (*Mense*).
724. Nield, J. ..... Receptacle for the rollers of mules or other spinning frames.
730. Bolze, H. A. ..... Double-acting injector apparatus.
734. Bunch, W. S. ..... Wrenches. (3rd September, 1890.)
736. McCool, W. A. ..... Metal bar, &c., polishing machines.

15th January, 1891.

741. Adams, M. J. ..... Engines and motors.
742. Stoner, W. ..... Pulley for regulating and insuring uniform speed in gas, steam, or other engines and machinery.
751. Stuart, D. ..... Fibre-cleaning machines.
770. Horton, J. ..... Apparatus for preventing the greasing of fabrics in tentering machines.
771. Binns, G. A. ..... Reed stripper for carding engines.
775. Richards, L. H. ..... Typewriting machines.
782. Ainsworth, I. N. ..... Loom pickers.
784. Jameson, J. ..... Automatic governor for steam engines (*Tuckfield*).
788. Wrigley, T. ..... Spindles and bobbins for ring and traveller spinning and doubling frames.
791. Brewin, A. ..... Warp lace machines.
798. Mottershall & Macey ... Typewriting machines.

16th January, 1891.

815. Wilson, A. ..... Steering gear.
816. MacCallum, P. F. ..... Caloric engines.
825. Sutcliffe, W. ..... Looms.
826. Brown & Mackay ..... Paper-making machines.
834. Miller, A. ..... Gas, hydrocarbon, and other explosive power engines.
835. Dunn & Dunn ..... Water gauges of steam boilers.
841. Von Blinsdorf & Adler Railway signalling apparatus.
842. Kämmerer, P. ..... Automatic measure-testing machines.
851. Davis & Taylor ..... Railway fog signalling apparatus.
856. Stalker, J. J. ..... Steam engines.

17th January, 1891.

862. Turton, W. H. ..... Locomotive boiler.
863. Walker & Walker ..... Lubricator.
870. Tweedale, J. T. ..... Stop motions for cotton preparing machinery.
879. Hargreaves, R. H. ..... Water tube steam boiler.
882. Atkinson, J. ..... Fluid pumps, meters, and motors.
883. Ramsey & Croasdell ..... Rock drilling.
888. Weiss, R. ..... Weaving apparatus
889. Woodhouse & Rawson United, Ld. ..... Apparatus for manufacturing corrugated lead boxes for electric accumulators (*Steanes*).
894. Lindley, H. ..... Valve operating mechanism of steam engines.
898. Barton, J. B. ..... Water gauges for steam boilers.

ELECTRICITY.

12th January, 1891.

584. Hautin & Leblanc ..... Alternate current dynamo electric motors.
587. Berlyn, F. H. P. ..... Incandescent lamps.
593. Coad, T. ..... Primary batteries.

13th January, 1891.

608. Parker, T. ..... Conduits for street electric conductors.
616. Allison, H. J. ..... Carbon pencils for arc lamps (*Ward*).
617. Allison, H. J. ..... Arc lamps (*Ward*).
647. Lake, H. H. ..... Electrical measuring instruments (*Weston*).
649. Lake, H. H. ..... Electric elevators (*Eickemeyer*).
657. Lake, H. H. ..... Conduits for electric conductors (*Lord*).
667. Thompson, W. P. ..... Electrodes for voltaic accumulators (*The Hess Electric Storage Battery Company*).
668. Thompson, W. P. ..... Voltaic accumulators (*The Hess Electric Storage Battery Company*).
669. Puluj, J. ..... Cut-outs.
675. Ball, R. E. ..... Electric regulator.

15th January, 1891.

743. Rooper, W. O. ..... Application of electricity for mining purposes.

16th January, 1891.

846. Morten, W. V. ..... Electrical cables.

17th January, 1891.

871. Bennett & Hides ..... Telephone transmitters.
884. Wells, C. ..... Apparatus for the production of electricity.
899. Eager & Milburn ..... Electric cells or batteries.
908. Ross, F. A. ..... Insulators for electric wires.
910. Clark, A. M. ..... Electromagnetic mechanism for controlling the transmission of power (*Kilbourn*).

CHEMISTRY.

12th January, 1891.

551. Dawson & Hirsch ..... Colouring matters.
583. Durand, Huguenin, & D'Andiran (trading as La Société L. Durand, Huguenin, & Cie.) ... Colouring matters. (13th June, 1890.)

13th January, 1891.

684. Astrop & Parker ..... Manufacture of carbonate of lead or white lead and apparatus therefor.

16th January, 1891.

843. André & Curtis ..... Manufacture of gunpowder and apparatus therefor.
857. Pitt, S. ..... Colouring matters from triphenylmethane (*L. Cassella & Co.*).

17th January, 1891.

891. Imray, O. ..... Obtaining pure nitric acid (*The Farbwerke Greisheim-on-Main*).

MISCELLANEOUS.

12th January, 1891.

549. Noble, K. D. ..... Driving of screw propellers.
557. Tucker & Harbord ..... Removal of scale from iron or steel sheets, plates, &c., and apparatus therefor.
566. Drake, H. ..... Aërial and submarine propellers.
595. Wise, W. L. ..... Process of dyeing or treating fibres (*Schniter*).

14th January, 1891.

707. Sinnette, F. J. ..... Rivets, bolts, and nuts.

16th January, 1891.

823. Williams & Morris ..... Piston rings.

17th January, 1891.

892. Haddan, H. J. ..... Rivet and bolt cutter (*Helwig*).

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

17471. Budd. 18294. Flint & Michell.
20486. Britchett & Low.

1890.

498. Vialet-Chabrand.
865. Lorrain.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Stop Valves.—*G. M. Marchant, Huddersfield.*—The invention relates to expanding plugs for parallel screw valves. Fig. 1 in the illustrations is a vertical section, and Figs. 2 and 3 cross sections of a valve embracing the principle of this invention. On each side of the nut A are two halves of a plug or block B and C divided vertically in an angular direction, as shown in plan view (Fig. 2). These plugs B and C are each provided with a wedged or inclined side piece D, and are arranged to come into contact with inclined or wedge-shaped surfaces E formed within the valve casing F, so that when the spindle G is operated in a downward direction the side pieces D are forced down the inclined surfaces E in such a manner as to force the plugs B and

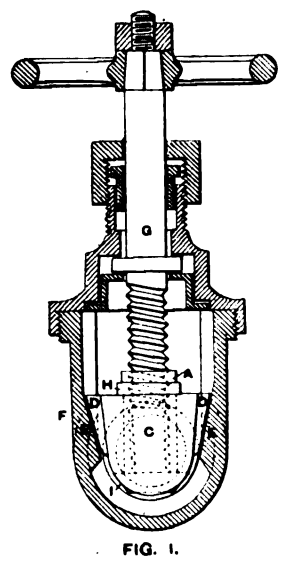

FIG. 1.

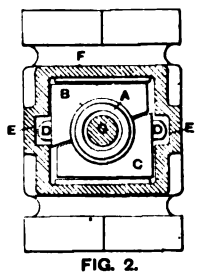

FIG. 2.

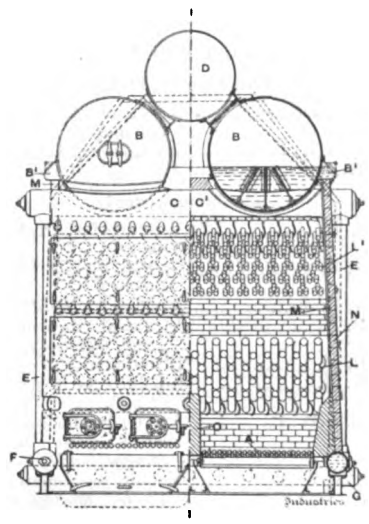
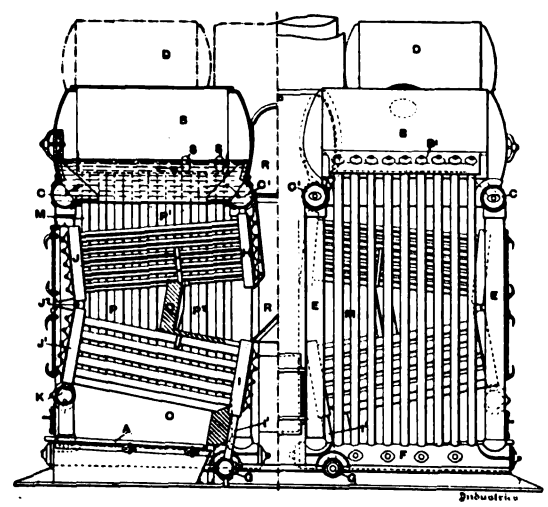
FIG. 3.



C sideways laterally, which brings the two halves of the divided plug into position, shown in Fig. 3, the effect of which is to widen the two plugs, forcing them apart in the direction indicated by arrows, whereby the outer face of each plug is thrust with considerable pressure against the interual face of the valve. On the screwed spindle G being reversed and the side pieces D made to slide upwards vertically, the parts B and C are slackened to permit of the valve being opened. The two halves of the plug B and C surround the nut A between the upper collar H and the lower collar or flange I of Fig. 1. The inventor also describes other methods of effecting the above. Claims: (1) In parallel screw-faced valves, the use of a divided plug or block having inclined or wedge-shaped surfaces operated so as to be forced against the valve seating in manner substantially as described; (2) the combination therewith of plugs expanded laterally by cam, wedge, or scroll-shaped surfaces; (3) the combination therewith of oscillating discs or expansion plugs widened laterally by cam or screwed surfaces; (4) the combination therewith of oscillating discs or expansion plugs operated in combination with intermediate plates; (5) the combination of a screwed nut and one expanding surface, operated laterally by cam, wedge, or scroll-shaped surface.—No. 1718. February 1st, 1890. 8*d*.

Looms.—*I. Kirkbridge, Colne, Lancashire.*—The invention relates to an arrangement of springs as a substitute for the weights now used to impart drag or friction to the warp beam. The chains or ropes are wound in the usual manner round the collars or necks of the warp roller, but instead of attaching such chains or ropes to the weighted levers, they are each attached to spiral springs, one at each end of the loom, connected to a cross-bar extending from spring to spring. A screw bolt, acting in a chased bracket at the centre of the bar, is employed to impart more or less tension on the springs as may be required, and a pointer moving over a fixed dial is employed to indicate the amount of pressure or tension placed upon the springs. Claims: The combination of said parts for applying friction or drag to warp beams and the employment of an indicator for giving the amount of tension applied to warp beams, substantially as described.—No. 2911. February 24th, 1890. 6*d*.

Pipe Couplings.—*R. Curry, G. Mackie, T. Souter, & G. B. Hughes, all of Newcastle-on-Tyne.*—The invention is intended to dispense with solder and screwing the ends of pipes, to accomplish which the inventors use a male and female coupling outside the pipe to force it upon a double-coned tube inside the pipe, maintaining thereby the full area of the pipe and a clear way without any resisting shoulders. In the case of joining lead or soft pipes to iron or hard pipes, the inventors use one-half of the coned tube before mentioned, with a recess in it to receive the iron pipe. This is placed inside the lead pipe, and on the iron pipe is placed a piece of lead or soft tube. The external and internal couplings are then screwed together, forcing the lead pipe on to the single cone, and the short piece of lead pipe is forced by an internal cone turned in the coupling on to the iron pipe and against the end of the single cone. Claims: Four claims are made, embracing the arrangement of pipe couplings as described, with modifications to suit the junctions of taps and cocks to pipes, &c.—No. 11346. July 21st, 1890. 6*d*.



Sectional Steam Boilers.—*W. Fairweather, Glasgow.* (*N. W. Pratt, & the Babcock & Wilcox Company, New York, U.S.A.*)—A front elevation partially in section is shown in Fig. 1 of the accompanying illustrations, and Fig. 2 is a side part sectional

FIG. 1.

elevation, the fire bricks between the vertical tubes being omitted, of a double sectional steam boiler constructed according to this invention. A are the separate fire-grates. The two steam drums B placed side by side are connected together by pipes C C¹, and through the common steam drums D. E are the vertical downflow pipes supporting C and C¹ and forming a communication therewith and the longitudinal distributors F, which are connected together by transverse pipes G. The headers H are supported by and communicate with the tubes C¹. The headers I are supported by and communicate through pipes I¹ with pipes G. The headers J J¹ connected together by nipples J² are supported by transverse tubes K connected to tubes E. The headers are serpentine in form, and are connected together by water tubes L L¹ as shown. Connection is made between drums B and pipes F by means of connecting boxes B¹ and tubes M, which pipes form the side work of the furnaces, being filled in with firebrick sections N. The dividing wall O separates the fuel spaces, but after passing above the same the hot gases mingle in the common combustion spaces P P¹ passing thence through tubes L¹ into space P² separated by wall Q and thence to common flue R. In operation, the circulation is passed upward from the transverse distributors G, through the uptake tubes I¹ and

FIG. 2.

generating tubes L first, the same body of water thence circulating a second time under exposure to the hot gases through the tubes L¹, where the heating surface is furthermore increased. The opposite inclinations of the successive groups of tubes promotes the reverse circulation, the steam and water being finally delivered through the transverse pipe C¹ to the drums A. The water also circulating upwards from the pipes F, through the wall tubes M, and discharging through the openings S, at the water level in the drums, throws the currents forward in a common direction into the cross pipe C, thence downward through the downtake pipes E, chiefly at the fronts of the boilers. Nine claims are made.—No. 17673. November 4th, 1890. 8*d*.

Apparatus for Repairing Spinning Rings.—*F. M. Marcy, Worcester, Massachusetts, U.S.A.*—The apparatus for the above purpose consists of two horizontal metal plates held at a suitable distance apart by means of distance pieces. Running in a step-bearing in about the centre of the lower plate, and in a bearing in the upper plate is a vertical shaft carrying on its upper end, which projects above the upper surface of the upper plate, a cup-shaped socket to receive the spinning ring to be repaired, and which is held therein by means of a set-screw. Between the two plates this vertical spindle carries a bevel gear-wheel, which gears with a bevel pinion on one end of a horizontal shaft running in a suitable bearing formed on the under side of the upper plate. The latter carries at its other end a pulley, by means of which the power for operating the apparatus is applied. Fixed on the upper surface at one end of the upper plate is a vertical arm, to which is fixed a horizontal arm, having formed on its outer end a suitable head. This head is provided with a vertical groove, in which slides the track expanding die, and which is forced down upon the upper surface of the flanged track of the spinning ring by means of a screw passing through the upper part of the head and pressing against the end of the die. Hinged to the upper part of the head on the horizontal arm are two steel bars forming the side dies. The lower ends of these side dies are turned inwardly to form lips which extend beneath the flanged track of the spinning ring and press against the waist of the said ring. Upon the inner sides of these side dies are formed scraping lips, which in the operation of the machine are brought against the edges of the flanged track of the spinning ring. Pressure is applied to these side dies, so as to press them towards one another, by means of set screws carried in one end of swing arms, the other ends of which are attached to a rocking shaft journaled in the horizontal arm carrying the block. Eight claims are made, embracing the general construction of an apparatus as and for the purpose described, together with modifications.—No. 17706. November 4th, 1890. 8*d*.

Grinding, Milling, and Burnishing Machines.—*W. J. Hands, Harborne, Staffordshire, & A. Price, Sparkbrook, Birmingham.*—Fig. 1 in the accompanying illustrations is a front elevation, Fig. 2 an end view, and Fig. 3 a plan of an apparatus constructed according to the invention and for the purpose of dressing stamped, cast, or pressed articles. The grinding tool A is fixed on the end of a spindle B rotating in bearings C carried by a pair of triangular-shaped frames D that are mounted to turn upon a driving shaft E, so allowing the cutter to be raised or lowered. The shaft E is mounted to run in bearings F carried by standards G on a base-plate H, and carries fast and loose pulleys as shown. To the cutter spindle B is fixed a toothed wheel I that gears with another toothed wheel J fixed to

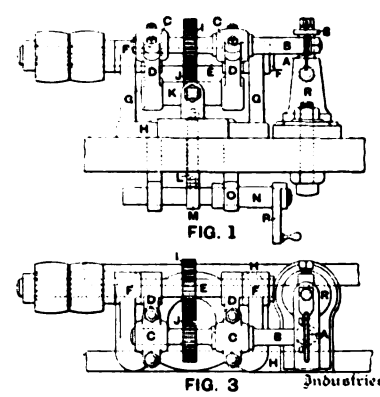


FIG. 1.

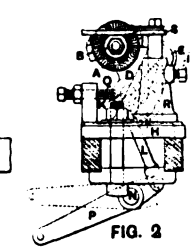

FIG. 2.

FIG. 3.

the driving shaft E, and by which the cutter spindle is driven. To enable the frames to be readily raised and lowered to suit the work to be done, they are connected by a rod K to which is jointed one end of a connecting rod L, the other end of which is jointed to a lever arm M fixed on a shaft N working in bearings O and operated by a lever handle P that may be actuated either by hand or foot. By these means the rotary cutter can be readily raised and lowered to any required position while the machine is in motion. Q is an adjustable stop screw to limit the upward movement of the frames D. R is a hollow support for a vertically adjustable rest S upon which the work to be dressed is placed. This rest is formed with a slot for the passage of the rotary cutter or burnisher, and is provided with suitable pegs and with a holding-down gauge to hold an article in position. Claims: (1) A grinding, milling, and burnishing machine constructed with a rotary cutter spindle carried in pivoted frames and capable of being raised and lowered whilst it is rotating about its axis, and mechanism capable of being actuated by hand or foot power for raising and lowering the said cutter spindle as described; (2) in a machine of the kind above referred to, a slotted rest adapted to support the article to be dressed, and provided with suitable gauge or stop pegs.—No. 18072. November 10th, 1890. 6*d*.

Cropping Machine.—*J. Beever, Huddersfield.*—The invention relates to cropping machines or "perpetuals" employed for shearing hearthrugs, carpets, and other like fabrics, the object being to prevent the end of the rug being sheared from being lifted, and so damaged by the revolving cutter used in such machines. The inventor, to accomplish this object, places close to the underside of the helical cutting edge of the revolving cutter a number of thin copper, steel, or other metal wires, arranged transversely or at an angle to the axis of the cutter. The carpet or rug to be operated upon travels underneath these wires, which prevents the edge of the fabric being drawn up by the cutter, but as the wires are fine they form no impediment to the proper shearing of the fabric. Each wire is attached to a thumbscrew arranged in suitable framework, so that the tension of the wires can be regulated. Claims: (1) In machines for cropping or shearing hearthrugs and other similar fabrics, the combination therewith of cross-wires, forks, or fingers employed in the manner and for the purpose set forth; (2) in machines for cropping fabrics, the combination of cross-wires together with means of adjusting the tension thereof in a manner substantially as described.—No. 2929. February 24th, 1890. 6*d*.

Digitized by Google

PULLEYS.—*H. H. Lake, London.* (*F. B. West, San Francisco, California, U.S.A.*)—Sheaves or pulleys are constructed as follows according to this invention:—The outer periphery is made in two sections firmly bolted or otherwise secured together. The radial arms or spokes are each provided at their outer ends with a head or flange bevelled on its outer edge. The sections of the rims are provided, on their inner edges, with recesses, the inner walls of which are bevelled to receive the bevelled heads of the radial arms or spokes. These spokes are provided on one side with a projection or stop, so that, when the grooved rim is forced into place on the radial arms, the said rim will abut against this projection, and thus ensure the rims being fixed centrally on the radial arms. The grooved rim is secured to the radial arms by bolts passing through them and each of the bevelled heads. The pulley is divided into sections through two of the radial arms, which are provided with suitable bosses or flanges by means of which the two parts may be secured together. Three claims embrace the construction of sheaves or pulleys substantially as described.—No. 13005. August 19th, 1890. 8*d.*

CONDENSING APPARATUS FOR STEAM ENGINES.—*J. Y. Johnson, London.* (*J. A. Damey, Paris, France.*)—In the annexed illustrations Fig. 1 is a side elevation, and Fig. 2 an end elevation of

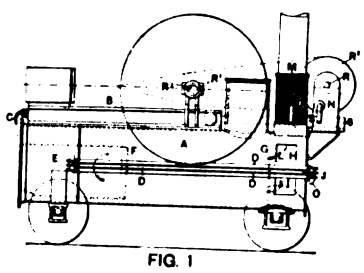

FIG. 1

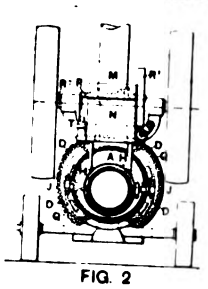

FIG. 2

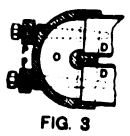

FIG. 3

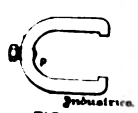

FIG. 4

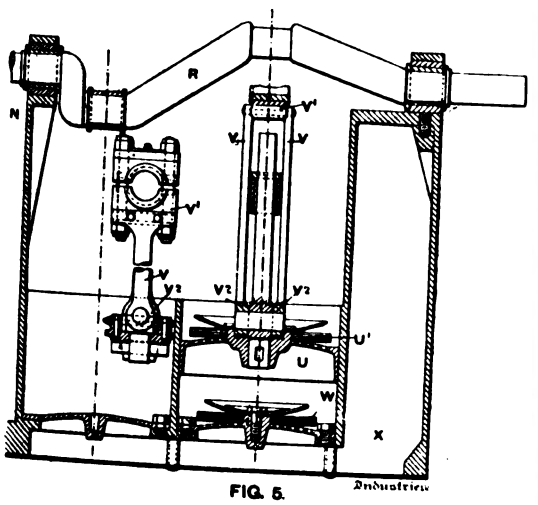
a portable engine with a condensing apparatus constructed according to this invention, Figs. 3 and 4 being enlarged details thereof, and Fig. 5 a horizontal section of the air pumps. A is the boiler, the feed-water pipes of which are heated by the exhaust steam in the hollow bed-plate of the engine B, as described in a prior patent, No. 19418 of 1889, and are connected by a pipe C to the superheating pipes D arranged in the side flues and heated by the products of combustion from the fire-box E, which pass from F to G in the boiler tubes and flow under a plate H through an opening I back to the front under a horizontal partition at J, finally returning through K to the opening L leading into the upper part of the smoke-box and passing into the chimney M. The tubes D are connected together at their ends by U-shaped junction pieces O secured by bails P (Figs. 3 and 4), and are covered with a non-conducting jacket Q. N is the condenser worked by a crank R driven at a lower speed than the engines by means of pulleys R^1 R^2 (Fig. 1). With this condenser is combined an injector S in connection with a condensation indicator and a feed pump T driven from R. The two air pump pistons U (Fig. 5) are operated by connecting rods consisting of two rods V attached at their upper ends to a block V^1, with bearings working on the cranks, and formed with an eye V^2 for connecting them to the piston U of the pump. The pistons U are perforated and carry a disc U^1 of flexible material



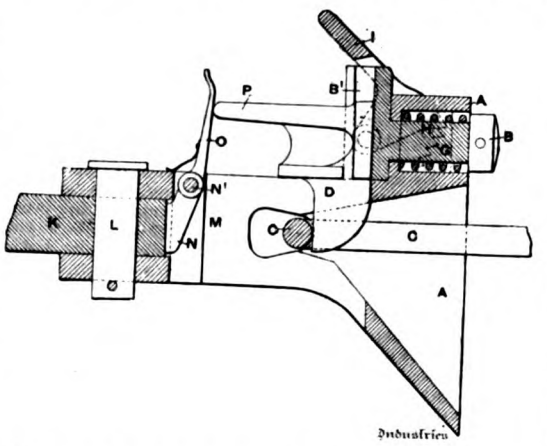


FIG. 5.

for closing such perforations. The suction valves W leading to the chamber X, in which the injection takes place, are of the usual construction. Four claims are made.—No. 19494. December 4th, 1889. 8*d.*

ELEVATORS.—*M. J. Paul, London.*—The invention relates to apparatus for coaling ships or for conveying coal or other such cargo in bulk to wharves or other places of discharge. In carrying out the invention the inventor employs a barge or "lighter" provided with a travelling bed in the form of an endless chain arranged centrally, and which, after running the complete length of the "lighter," is then inclined upwards and passes over the extremity of a structure resembling the arm of a derrick. The outer end of this derrick arm may be raised or lowered by suitable means within certain limits to suit the level at which the cargo is to be discharged. The chain constituting the travelling bed is composed of links having formed on one edge of them projections in the form of teeth which are slightly inclined in the direction in which the chain travels, so preventing the material constituting the cargo to be discharged from the "lighter" falling back when ascending the inclined derrick-arm. The material of which the cargo consists is disposed in the lighter along each side of the horizontal portion of the travelling bed, and may be rapidly transferred thereunto by manual labour. Or the floors of the coal bunkers may be inclined towards the centre of the lighter, and may be provided with sliding doors which, upon lifting, release the coal or other cargo, and permit it to fall upon the travelling bed. Two claims are made, embracing the arrangement substantially as described.—No. 2140. February 10th, 1890. 6*d.*

WHEEL VALVES.—*J. S. Smith, Nottingham.*—The invention consists of improvements in screw or wheel valves, but is also applicable to retention and other valves, in which the passage through them is closed by a plate or disc being pressed upon a seat. In applying the invention to small valves the inventor makes the seat solid with the valve casting, and it is designed to give a double bearing to the valve or disc. In section it somewhat resembles the letter L with a semi-circle described upon the horizontal line, and a quarter of a circle described tangentially to the top of the vertical line. The valve is made of a composite metal, copper and lead being used as ingredients, and its shape is a flat disc with the outer edge inclined at about 20° with the spindle, the smallest diameter being at the bottom. This valve or disc is attached by screws to a circular plate, so as to be easily replaced when worn, and the plate is carried by the spindle, and is free to rotate thereon. For "junction valves" the inventor forms the seating of a ring of brass or gun-metal fitted into the casing, the valve being made of a ring or disc of composite metal. Claims: The use in valves and other similar articles of a double seat constructed substantially as described, in combination with a disc of compressible metal or mixture of metals designed to bear upon both seats at the same time.—No. 11143. July 17th, 1890. 6*d.*

CAR COUPLINGS.—*A. E. Schurr, Romford, Essex.*—The invention refers to automatic central buffer couplings, in which the slack is automatically gathered, and at the same time the couplings are released from a clutch holding them in a central position, and allowing them to radiate to suit the curves on the railway. The annexed illustration is a sectional side elevation of such a coupling. B is the auxiliary buffer fitted to the coupling, and carrying at the rear the detent in vertical slides B^1 formed with the said buffer head B; after the coupling links C have engaged the detents D (by the lifting and falling of the said detents in the slides B^1), the said buffer or buffers B come in contact, are driven

back and carry with them the said detents D, thus gathering the slack. Each detent is held in position after the slack is gathered by a cam H (shown dotted) with lever I, which device H falls into position in toothed part G, formed on buffer head A, thereby effectually preventing the return of the detent D, and at the same time the auxiliary buffer is held withdrawn, thus allowing the main heads A to meet. The driving in of the auxiliary buffers at the same time causes the dog P to withdraw a clutch N by striking its lever arm O, which clutch has hitherto secured the draw-bar K and buffer head A in axial line with each other, and the said dog P prevents the clutch N from again gripping the draw bar and thus bringing it to, and securing it in a central position. The inventor also describes two modifications in which the auxiliary buffer is dispensed with, and the coupling link is utilised for operating the detent to take up the slack. Five claims are made, embracing the coupling as described, with modifications.—No. 2295. February 12th, 1890. 8*d.*

BALL GRINDING MACHINES.—*W. H. Wright, Buffalo, U.S.A.*—The machine for the above purpose, and constructed according to this invention, consists of following parts:—A framework, consisting of a vertical beam, on the lower end of which is formed an arm projecting outwards at right angles thereto, and the upper surface of which is of a circular shape. At its upper end or head, this beam is inclined forward in the same direction as the horizontal arm, so as to bring its end exactly over the centre of such arm. Centrally in the lower arm and in the upper end or head are formed bearings, in which runs the vertical driving shaft. At an equal distance from and on each side of this shaft are fixed two vertical rods, the upper ends of which are fixed in auxiliary arms on the head of the framework, and the lower ends being fixed on each side of the disc on the lower arm. Sliding on these two rods are two slides fixed to the periphery of an upper disc carrying on its under-side the upper grinding ring. This upper disc has an internally screwed boss in its centre, in which works a hollow screw embracing the vertical driving spindle and free to revolve, but prevented from moving longitudinally by the upper end, having a collar formed on it, which is embraced by suitable lugs fixed to the under-side of the head of the framework. Fixed below the upper grinding ring is the lower grinding ring, fixed to and carried on a disc revolved by the vertical driving spindle. In the opposite faces of the upper and lower grinding rings semicircular annular grooves are formed concentrically with the driving shaft and opposite one another, in which grooves are placed the balls to be ground. The grooves in the lower grinding ring have supplementary grooves formed in their lower sides to allow for wear. At diametrically opposite positions around the screwed boss on the upper disc are formed funnel-shaped openings leading into the interior of the upper and lower grinding rings, and in which funnels the grinding material and water, or other lubricant, is placed. This grinding material and water is so fed into the interior of the upper and lower grinding rings, and is, by centrifugal force, caused to escape between the opposite grooved faces of the rings, which are held slightly apart by the balls being ground. Three claims are made.—No. 17723. November 4th, 1890. 6*d.*

PUMPING ENGINES.—*J. Wright, London.*—Referring to the annexed illustrations, Fig. 1 is a front elevation, Fig. 2 a side elevation, Fig. 4 a vertical section, and Fig. 5 a horizontal section of an apparatus constructed according to this invention. A A^1 are the motor cylinders and B B^1 the pumping cylinders, the piston rods of the pistons of which are connected to the

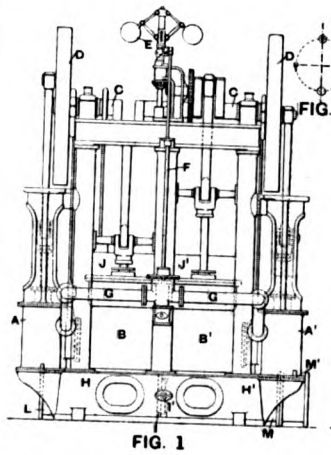

FIG. 1

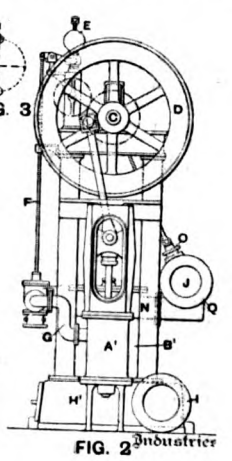

FIG. 2

crank-shaft C carrying the fly-wheels D as shown. E is an ordinary governor fixed as shown, and actuated by a gear-wheel on C, and acts by a rod F upon the throttle valve in the steam supply pipe G. The pump cylinders B B^1 at their lower ends communicate with the double chamber H H^1 divided by the partition I, and having an opening capable of being closed and opened by the valve L^1. The pump cylinders at the top communicate with a double chamber J J^1 also divided by a partition K, with an opening therein which can be closed or opened by the valve K^1. The pipe L leads from the condenser, and the pipe M leads to a water supply, which can be closed by the valve M^1. The pumps deliver by the pipes N into the chamber J provided with a pump O operated by an eccentric from the crank-shaft. This pump delivers feed-water through the pipe P from J into the boiler through a feed-water heater. The other end of J is provided with a pipe Q communicating with

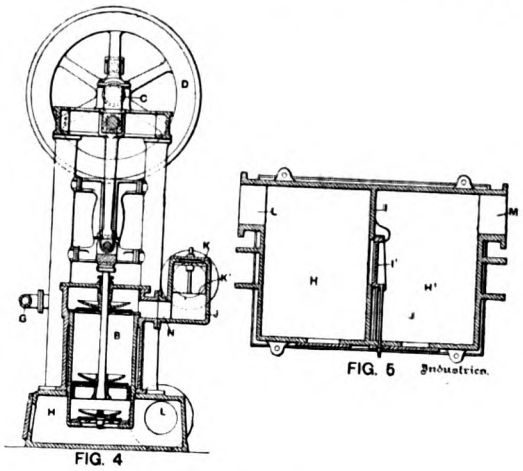

FIG. 4

FIG. 5

the water space of the condenser and operated by valve R. The apparatus may be used for pumping for any number of engines and boilers put into connection with it. Three claims are made.—No. 17859. November 6th, 1890. 6*d.*

LUBRICATORS.—*R. B. Helliwell, Liverpool.*—The lubricator constructed according to this invention is for use with lubricants of the solid class, and is intended for use on pulleys and other revolving parts of machinery, and is constructed as follows:—A cup of a shape similar to the ordinary cylindrical lubricator is used, the same having its inside turned truly cylindrical and having one hole in the centre of the bottom, passing through the stub-end and one or two holes communicating with the outer air also through the bottom. Within this cylinder a piston is fitted to move freely up and down therein, and from the centre of the piston projects downwards a tube of a size to fit easily the hole in the stub-end in which it is intended to slide, the tube being of such a length that if the piston be lifted up until it touches the cap screwed into the top of the cup, the said tube will still be within the hole. The action is as follows:—The lubricator being fixed to the boss of the pulley so that it is vertical to the axis of revolution, the piston is inserted, the cup above the top of the piston filled with lubricant, and the cap screwed on. As the whole revolves, the piston, by the action of centrifugal force, tends to force the lubricant upward, so causing it to escape through the tube in the centre of the piston to the bearing being lubricated. Above the top of the tube fixed to the piston a radial arm is pivoted on a screw screwed into the surface of the piston, which may be moved as desired to regulate the flow of the lubricant. Five claims are made, embracing the apparatus substantially as described.—No. 1124. January 22nd, 1890. 8*d.*

Digitized by Google

COMPOUND STEAM ENGINES.—*J. Klein, Frankenthal, Germany.*—The invention refers to engines in which the high and low pressure cylinders are placed side by side, a single slide-valve being used. The valve-box is placed on the opposite side of the low-pressure cylinder to the high-pressure cylinder, channels being formed around the exterior of the low-pressure cylinder leading to each end of the high-pressure cylinder. The valve-box face has five port holes in it, three in a row, the outer two of which lead to the low-pressure cylinder, and the central one to the exhaust and two other ports placed opposite to the two outer ones of the three, and leading to each end of the high-pressure cylinders. The valve is of a U shape, having in each arm and also between said arms indentations, which, when the valve is, say, in its uppermost position, opens a passage for steam from the lower end of the high-pressure cylinder to the higher end of the low-pressure, and admits steam from the valve-box to the higher end of the high pressure cylinder and forms a connection between the lower end of the low-pressure cylinder and the exhaust, as will be readily understood. The inventor claims in two claims the arrangement as described.—No. 17447. October 31st, 1890. 6*d.*

RING SPINNING AND DOUBLING MACHINES.—*G. Walker & W. Parker, Rochdale, Lancashire.*—The invention refers to the anti-ballooning wires which extend from end to end behind the spindles. These wires are carried upon and moved with the ring rail. At each end of the ring rail a bracket is secured which is slotted horizontally in a direction at right angles to the axis of the ring rail. Through each slot a screw bolt passes, and one end of the anti-ballooning wire is attached to an eye in the end of one screw bolt at one extremity of the ring rail, and the other end to the eye in the screw bolt at the other extremity of the ring rail. There is a screw nut upon each bolt to stretch the wire, but, in order that the wire may be kept in correct position without stretching it at too great a tension, there are brackets formed on the ring rail at intervals to sustain the wire in the required position and prevent vibration. Claims: (1) The combination of a wire, eye bolt, and slotted stands, or their equivalents (the wire being capable of being moved back for doffing), with the ring rail substantially as and for the purpose set forth; (2) the combination of a wire, eye bolt, slotted stands, intermediate supports for the wire, with the ring rail as and for the purpose described.—No. 3815. March 11th, 1890. 8*d.*

ELECTRICITY.

ARC LAMPS.—*H. Harper, London.*—The invention relates to means of regulating the feed of the carbon and of a method of constructing the solenoid-core so as to render it specially adapted for use with alternating currents. In the annexed illustrations Fig. 1 is a sectional elevation of an arc lamp embracing these improvements, Fig. 2 being enlarged details thereof. The solenoidal tube A, fixed as shown, has wound in layers around it between the gills B coils of coarse wire (not shown) connected

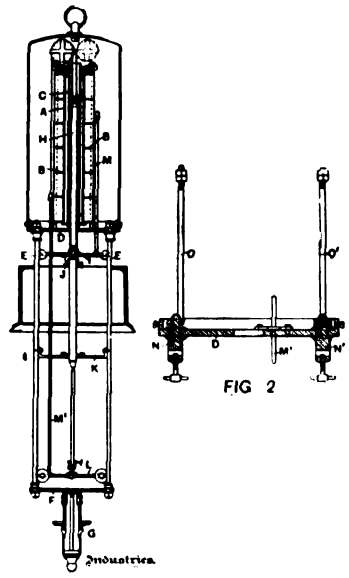

FIG. 1

FIG 2

in series with the lamp circuit. An inner coil of fine wire in a shunt to the lamp circuit is wound around the tube C inside A. The tube A and gills B are split longitudinally to prevent heating. Fixed to the plate D carrying A and C are two rods E, slotted longitudinally, the slots being on the inner and opposite sides, and connected together at their lower ends by cross-piece F carrying a gallery G for supporting a globe. The core H working in C consists of a number of insulated iron wires placed in a longitudinally slotted brass tube, the lower end of which is fixed to a cross-piece I, on the ends of which are rollers running in the slots in rods E, the cross-piece I carrying the upper carbon-holder J fixed to it by means of a ball-joint to allow of adjustment. The lower end of the upper carbon passes through a guide in a cross-piece K fixed to rods E. The lower carbon-holder is fixed by means of a ball-joint to a second cross-piece L also carrying rollers, in this case of an insulating material, running in E. Fixed to the top of core H are two cords passing over rollers, fixed as shown to the top of A, the other ends of the cords being fixed to rods M M^1 projecting from the cross-pieces I and L respectively. The positive wire from the generator is connected to the binding post N (Fig. 2), whence the current flows to the outer coil of the solenoid. From the latter it passes into the base of the rod O and along that rod, the top of which is electrically connected by a flexible wire with the rod M carried by the cross-piece I. From the rod M the current flows into the upper carbon, thence into the lower carbon, along the rod M^1, and through a flexible wire to the binding rod O^1, and thus to the binding post N^1 leading to the generator. Five claims are made, embracing the principal features of an arc lamp as described.—No. 17425. November 2nd, 1889. 8*d.*

TELEPHONE TRANSMITTERS.—*C. L. W. FitzGerald, London.*—The invention relates to transmitters in which granulated carbon is used. Fixed in a suitable holder are two carbon discs placed at a suitable distance apart and concentrically with one another. These discs are insulated from one another by means of a ring of indiarubber or other insulating material placed at their edges, and have connected to them the respective wires. In the space between the two discs a division of a curved or angular form is placed, which passes across the centre of the discs or thereabouts, and extends from side to side so as to divide the area between said plates into two spaces, in the upper of which the inventor places the granulated carbon. Claims: A telephone transmitter with the area between the two discs or plates divided by the partition as described into two spaces, so that the granulated carbon is contained in one of the said spaces, substantially as described.—No. 4028. March 14th, 1890. 6*d.*

INCANDESCENT LAMPS.—*A. M. Clark, London.* (*A. Bornholdt & J. Glatz, both of Brooklyn, U.S.A.*)—This invention relates to the manufacture of incandescent lamps and other vessels that are more or less exhausted of air, and to the mode of exhausting and sealing same. The bulb of the incandescent lamp to be exhausted is fitted with the ordinary hermetically sealed stopper, which on its inner end supports the filament, and on its outer end carries the connecting wires. Formed in this stopper is a small passage passing completely through it, the upper end containing a gravity valve. This valve is of a conical shape, so that it can be fitted firmly into the passage in the lamp stopper, the bottom thereof, on which the gravity valve rests, being finely perforated. These lamps, when so fitted, are placed in an inverted position in a suitable cylindrical vessel, and this vessel is then hermetically sealed and the air exhausted by means of a suitable vacuum pump. The air in the lamp bulbs is so also exhausted owing to the gravity valves being open by the bulb being placed in an inverted position. The cylindrical vessel containing these bulbs is then turned over, it being carried upon suitable trunnions for that purpose, and the gravity valves in the lamp stoppers so closed, and will be so held by the external atmospheric pressure when taken out of the cylindrical vessel, as will be well understood. Three claims are made, embracing the arrangement and method of exhausting incandescent bulbs and the like, substantially as described.—No. 19097. November 25th, 1890. 6*d.*

ARC LAMPS.—*W. P. Thompson, London.* (*R. H. Beach, St. Paul's, Ramsey County, Minnesota State, U.S.A.*)—The arc lamp embracing the principle of this invention is constructed in the following manner:—A cylindrical metallic casing is used, in the top of which two binding screws are placed, one being insulated from the casing, which two screws may be connected when the lamp is not required by means of a radiating arm pivoted on an extension of one screw and sliding on an extension on the other screw. Passing through the sides and bottom of the casing are the tubular carbon-holders, one being fixed and the other pivoted in the bottom of the casing to allow its lower end to be adjusted to the end of the other holder. Inside these tubular holders are placed the carbons, the same being pressed downwards by means of a following weight sliding in the tubes and pressing against the top of the carbons, the movement of the carbons being, however, somewhat retarded by means of springs, one end of which is fixed to the lower end of the holder, and the other end of which presses against the lower end of the carbon. Fixed in the upper part of the casing are two solenoids, the core openings of which are placed opposite one another and in the same horizontal plane. One of these solenoids is wound with coarse wire, one end being connected to the fixed and insulated carbon-holder and the other end to the insulated binding screw. The other solenoid is wound with fine wire, the ends being connected respectively to each of the binding screws. Working in these solenoids is a common core, in the centre of which is fixed a cross-piece, having one extremity connected to a helical spring, a second end being fixed to the casing, and the other end is connected by a hinged arm to the upper end of the pivoted carbon-holder. The action is as follows:—The current flows from the insulated binding screw through the coarse wire of one solenoid, so attracting the common core and moving the lower end of the pivoted carbon-holder from that of the fixed holder, so forming an arc. The resistance of the arc shunts a portion of the current through the finely-wound solenoid, which acts in opposition to the first solenoid, and checks the movement of the core, as will be understood. Six claims are made, embracing the arrangement of arc lamps as described, with modifications.—No. 19057. November 24th, 1890. 6*d.*

CHEMISTRY.

COLOURING MATTERS.—*H. H. Lake, London.* (*Wirth & Co., Frankfort-on-the-Main, agents for A. Leonhardt & Co., Frankfort-on-the-Main, Germany.*)—Dioxynaphthalene (melting point 216° C., obtained by melting β-naphthalenedisulpho acid or Schäffer's β-naphtholmonosulpho acid with alkalies) when heated with ammonia or primary amines, especially in the presence of a salt of such, can be converted into naphthylenediamine and its corresponding derivatives. These derivatives when treated with salts of nitroso-derivatives of aromatic amines (such as nitrosodimethylaniline or the like) yield green basic dyestuffs, which are very fast against the action of light and soap. The production of these colouring matters takes place in the usual manner by heating the two components in the presence of some dissolving and distributing agent such as spirit, acetic acid, &c. Examples:—1st. 10 kilos of diphenylnaphthylenediamine are heated with 200 litres of spirit, up to, say, 70° C., and about 10 kilos of chinondichlorimide gradually added, care being taken that the reaction does not become too violent by a too quick addition of the chlorimide. The fluid is then kept boiling at the reflux cooler for some time, diluted with hot water, the liquid filtered, and after cooling down the dyestuff precipitated out of the filtrate by means of common salt. 2nd. 20 kilos. of orthoditolylnaphthalenediamine, about 30 kilos. of the chlorhydrate of nitrosodimethylaniline, and 200 litres of methylic alcohol are heated at the reflux cooler, until all nitrosodimethylaniline has disappeared. The whole mass is then diluted with, say, 800 litres of water and filtered, and the colouring matter is precipitated out of the filtrate by means of common salt. By employing diphenylnaphthylenediamine instead of orthoditolylnaphthylenediamine, a part of the colouring matter crystallises out of the alcoholic solution on cooling and can be separated by filtering. Instead of the chlorhydrate of nitrosodimethylaniline, other salts of this base, as for instance the sulphate or nitrate, can be used. The nitrosodimethylaniline can further be substituted by an equivalent quantity of nitrosodiethylaniline. Four claims are made.—No. 3098. February 26th, 1890. 6*d.*

MISCELLANEOUS.

SUGAR BEETS SLICING APPARATUS.—*R. Bergreen, Roitsch, near Bitterfeld, Germany.*—The object of the present invention is to slice sugar beets, sugar canes, and the like in a uniform manner, and so that they do not lose their juicy properties, and also to so construct the knife edge that it will be more durable.

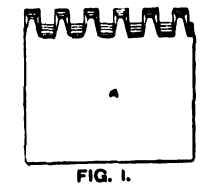

FIG. 1.

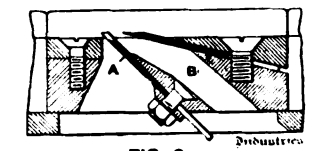

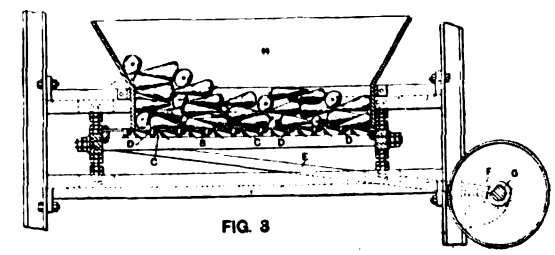

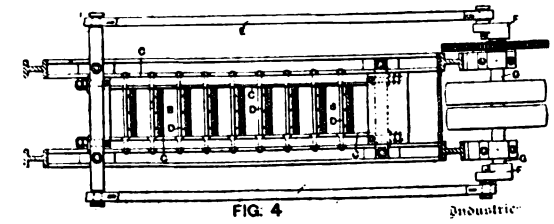

FIG. 2.

The knife A is formed with a zig-zag cutting edge, as shown in Fig. 1, and can be used alone or in conjunction with a second and plain knife B as shown in Fig. 2. Figs. 3 and 4 show a plan and side section of an apparatus constructed for the purpose of slicing sugar beets. The numerous knives A and B are fixed in a frame C, the knives B being adjustable in clamps D. The levers E attached to the knife frame C gives the latter a reciprocating motion under the hopper H, in which are the beets, and is actuated in the usual manner from crank F and eccentric G. The inventor also describes a modified apparatus for effecting the slicing of

FIG. 3

FIG. 4

sugar cane. Claims: (1) A knife for producing slices of beet, sugar cane, and the like, consisting essentially of a solid metal plate, the edge of which is cut in zig-zag fashion, producing points and indents (Fig. 1), such knives being attached to cutting frames of machines either singly or in combination with plain knives, all substantially as described and shown in the illustrations.—No. 20573. December 21st, 1889. 8*d.*

PIPE COUPLINGS.—*J. E. Matthewson, Sheffield.*—In securing indiarubber or other flexible pipes to steam pipe or nozzles, a metal clip is employed, which the inventor constructs in the following manner:—A strip of thin sheet steel or other suitable metal, of suitable length and width, is placed around the junction of the pipes, and the ends of this strip are flexibly connected to guide blocks or nuts by lapping the ends thereof round the front and top sides and connecting to the back. Through each block or nut a hole is made to receive a close fitting bolt for drawing the blocks together. Underneath the ends of the clip a short thin piece of sheet metal is placed (of the same width as the clip band), to prevent friction on the soft material of which the flexible tube is composed. The blocks being flexibly connected to the ends of the strip of metal will slip readily on the surface of the tube and no angles will be presented when tightening up to cut into the flexible tube. Claims: (1) The improvement in metal clips as described, and consisting of the combination with a flexible strap of blocks round or partially round which the ends of the straps are lapped, a bolt to be passed through the blocks and straps, and a nut for drawing the blocks together on the bolt as and for the purpose described; (2) in a metal clip, the ends of which are secured together and tightened up by a bolt and nut, the use of blocks, the undersides of which are free or not, attached to the strap, as and for the purpose described.—No. 5580. April 12th, 1890. 6*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., ***Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every*** 10***d. or fraction of*** 10***d. Remittances exceeding one shilling must be made by Post Office Order.***

DEEP WELL PUMPING.

We had recently an opportunity of inspecting a method of obtaining water from deep wells, which has been devised by Messrs. Kilner & Matthews, West Gorton, near Manchester. The difficulty in raising water from great depths has generally been that of creating sufficient vacuum to induce the water to rise into the pump. In most cases the pump is put in the well at about the level of the top of the bore-hole, and it is necessary for the water to rise to the level of the pump before it can be raised to the surface. In many cases this plan has been practically impossible, and the quantity of water got has only been a fraction of the amount absolutely available. Messrs. Kilner & Matthews adopt the plan of forming the pipe lining the bore-hole into the barrel of the pump, in which they fit the bucket. Instead of placing the latter above the top of the bore-hole they carry it down to a sufficient distance to ensure that it shall always be covered with water, in many cases, indeed, placing it almost at the bottom of the bore-hole. In the well which we inspected this arrangement was carried out. The well is about 60ft. deep, the bore-hole extending downwards beyond that another 80ft. Near the bottom of this bore-hole the bucket is placed. The clack valve is fixed above instead of below the bucket, and the result of this arrangement is that the amount of water lifted is considerably increased. Instead of it being necessary to lift the water out of the bore-hole before pumping it, the bucket, being always immersed and working in the water, is simply required to pass it on its downward stroke and lift it on its upward stroke. This apparently simple alteration has had remarkable results in the plant we saw. When the old style of pump was fixed the yield was only 1,600 gallons per hour, while at the present time the well easily yields 5,600 gallons per hour. The extreme ease with which the pump works is well shown when it is stated that the pump rod only protrudes above the top of the bore-hole 1ft. or 2ft., and is then coupled directly to the crank by a connecting rod about 48ft. long, which works entirely without slides. Ordinarily this arrangement would give a large amount of vibration in the pump rod, and it is scarcely likely that it would work with sufficient steadiness to be practicable, but in this case the vibration was practically nil. The makers have carried out a number of similar arrangements, and all have resulted in a great benefit to the persons using them. For dyers, bleachers, brewers, and many other trades, the advantage of a supply of water of uniform temperature and composition is undoubted, and only the difficulty of obtaining a sufficient volume has hitherto prevented pumping being largely resorted to. In many places, by the arrangement now described, this difficulty could be entirely obviated.

THE CHIGNECTO SHIP RAILWAY.

II.

(*Concluded from page* 98.)

The gridiron of the lift, which is similar to a double-track bridge floor, and is really a movable section of the railway, has placed upon it the cradle, made up of flat cars of peculiar design, running on four lines of wheels. At the London offices of the company in Dashwood House there is on view a working model of the ship-lift, made under the direction of the engineers, which illustrates the extremely simple process by which the ship is transferred from the water to the rails or the reverse. The accompanying illustrations, Figs. 4, 5, and 6, represent this model as seen at three different stages of operation—viz., Fig. 4 shows the vessel floating over the cradle and gridiron ready to be raised, Fig. 5 shows the vessel blocked on its cradle and on the line of railway, and Fig. 6 shows the vessel on the cradle and gridiron in position ready to be lowered into the water again. When a ship is in the dock awaiting transportation, the gridiron, with the cradle resting upon it, is lowered to the bottom of the water in the lift. The ship is then floated into the lifting dock, and placed precisely over the cradle (Fig. 4), which is then raised to the level of the keel, when the supporting blocks are fitted accurately to the bottom and bilges. When thus in position, the pumps are started, and in about ten minutes the gridiron reaches the level of the track, with which its own rails exactly coincide, and to which it is firmly locked, as well as to the sides of the quays, so that it becomes an integral part of the railroad. A hydraulic gear draws the cradle from the gridiron to land, two locomotives are attached, and in less than two hours it will have reached the other end of the line. Here the lifting process is reversed, and when the gridiron has been lowered into the water the ship sails or steams away on her voyage. In order to use the line in both directions at the same time,

THE CHIGNECTO SHIP RAILWAY.

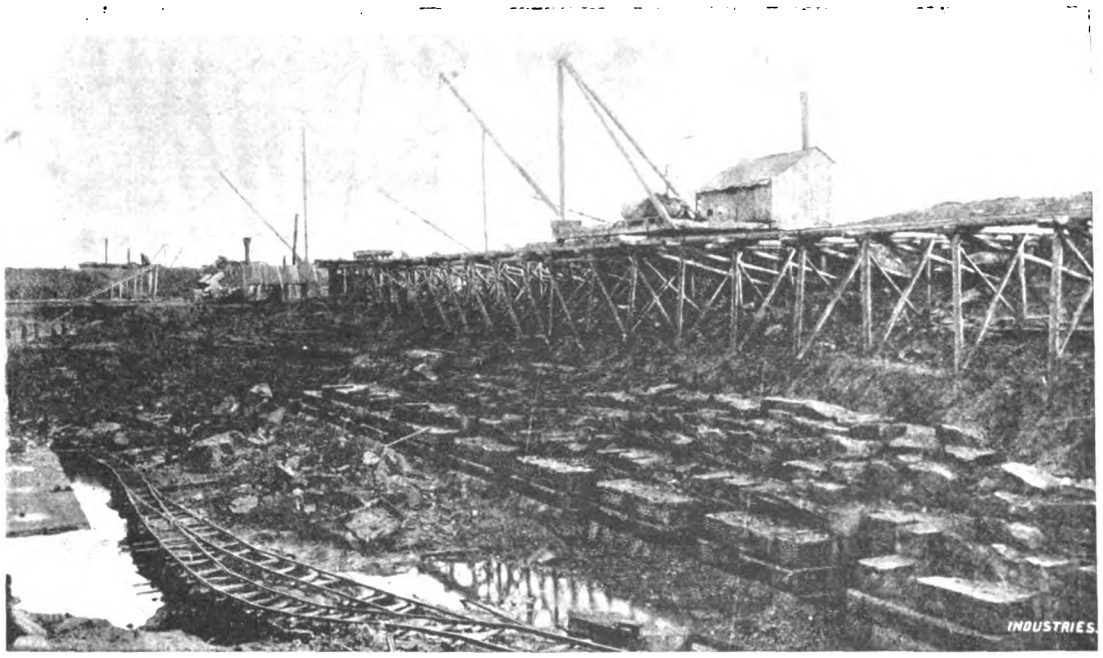

Fig. 7.—Interior of Cofferdam showing the Masonry of Lifting Dock.

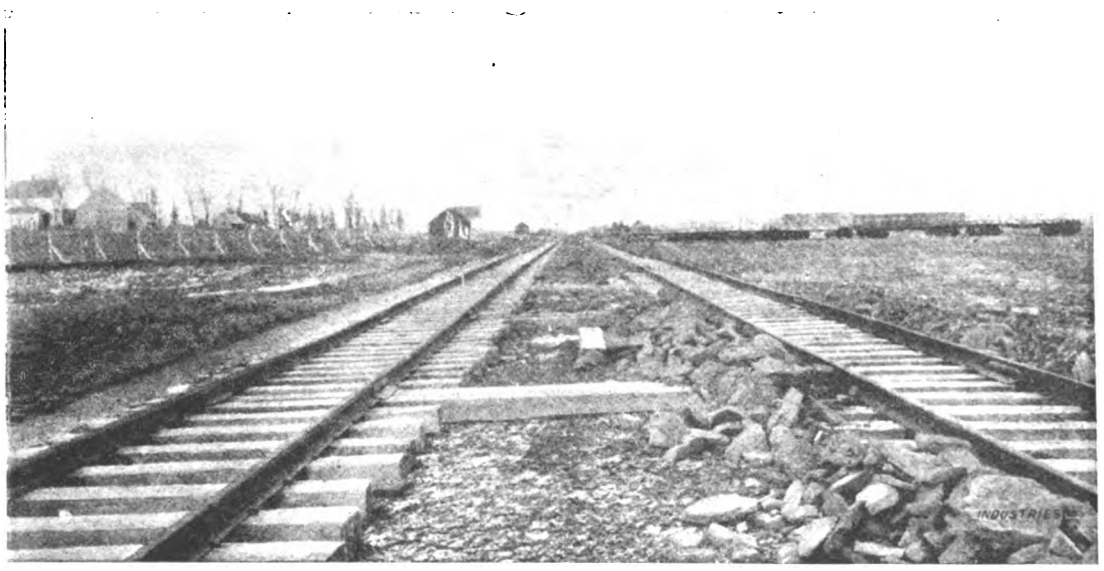

Fig. 8.—View showing the Double Railway Track Ready for Ballasting.

traversers will be used, so that ships may pass each other. By means of a division of the cradles it will be possible to haul two or three small vessels at one trip. The cradles to be used are being manufactured by Messrs. Handyside & Co., Limited, Britannia Iron Works, Derby.

At the Tidnish terminus on the Gulf of St. Lawrence it was found necessary to construct a cofferdam for laying the masonry of the lifting dock. Fig. 11 (see page 132) represents this cofferdam before the water was pumped out, with the moles of the outer dock behind. Fig. 7 is a view within the cofferdam showing the masonry of the lifting dock, and Fig. 3, given on page 99 of our last week's issue, shows the recent progress of the work. The moles which form the sides of the outer dock at Tidnish are of round timber cribs to the level of low water, above which they are of hewn spruce. They are divided into 10ft. square weighting chambers by longitudinal and transverse bulkheads, filled with rock, and surrounded by 12in. by 12in. square piles.

The basin is being dredged to a depth of 20ft. at low water. The dredging of the channel, which will extend about a quarter of a mile, is nearly completed. No locked basin is required here as at the Bay of Fundy terminus, since the rise and fall of the tide seldom exceeds 7ft.

The rails are already laid for one track half-way across the isthmus. Fig. 8 shows the double track, with its heavy rails and sleepers prepared for ballasting. Fig. 9 represents the closing of the last embankment on the line, together with the 30ft. arch culvert for the diversion of the Tidnish River.

Fig. 10 shows the great cutting at Tidnish, now completed. It is two miles long, and as the road bed has a uniform width of 40ft. for the whole line, half a million cubic yards were excavated from this cutting. The view shows also the side drains and bottom ballast. The progress of the hydraulic lifting dock at Amherst is shown in Fig. 12 (see page 132), together with the engine and boiler houses and accumulator.

From what has been said, it will be seen that the expectation of the company of having the work finished by October next, has every chance of fulfilment. That the enterprise will be successful from an engineering point of view can scarcely be doubted. All the operations are such as are in common use, the only novelty being in their application on a larger scale than heretofore. That it will be a commercial success may as fairly be anticipated. The whole cost of the work will be £1,100,000 sterling, a much smaller sum than was ever estimated as the cost of a canal. The running expenses of the railway, as estimated by Sir Benjamin Baker, should not exceed £30,000 per annum. A very small percentage of the enormous coasting trade of the Canadian waters would give the line profitable employment, and the easier access to markets afforded by the railway will doubtless add greatly to existing trade. No one will grudge the largest success to the spirited engineers and capitalists who have so resolutely faced the difficulties of the undertaking.

THE INSTITUTION OF CIVIL ENGINEERS.

At a meeting, held on the 27th ult., Sir John Coode, K.C.M.G., President, being in the chair, a paper was read on "Machine Stoking," by Mr. John Frederick Spencer, M.Inst.C.E.

Steam engineering, he said, included three processes—namely, the combustion of fuel and production of heat, the generation of steam, and the utilisation of steam. The paper was limited to the first of these. Experience had shown that with hand-firing sometimes a quantity of oxygen, sufficient for the complete combustion of the fuel, was found in the waste gases leaving the boiler flues, this excess of the air supply being due to the difficulty of mixing the carbon and the oxygen perfectly. The inequalities of hand-firing were twofold. First, air was admitted at the wrong time and place; and, secondly, the fuel was added according to the pressure gauge, the imperfect human feeding machine being thus the direct cause of a great waste of fuel, and of a large portion of the smoke produced. Steamship owners paid heavily for their human stokers, especially at the present time, when an Atlantic steamship might require from ten to fifteen tons of coal per hour.

James Watt patented a machine stoker in 1785. It was worked by hand, and consisted of two sets of bars, one behind the other, the fuel being fed at the front, and pushed towards the back as it ceased to smoke, the smoke from the fresh fuel passing over and through the more advanced combustion at the back end of the grate. A brief reference was then made to the principal steps in the development of machine stoking since that time, and one of the most successful machines of each type was selected for illustration—namely, the "coking" stoker of Messrs. T & T. Vicars, of Liverpool and Earlstown, and the "sprinkler" machine stoker of Mr. E. Bennis, of Bolton. There were two distinct types of machine, which were called coking and sprinkler stokers, and were both fed with coal from a hopper. In the coking stoker fuel was pushed slowly on to the dead-plate, movable bars being provided for carrying it forward at a speed intended to be proportionate to the rate of combustion required. In the sprinkling system the fuel was more or less evenly distributed over the grate by fans, beaters, or shovels, with or without movable bars. In both systems it was claimed that when it arrived at the farther end of the furnace there was nothing left but ash and clinkers, which dropped into a space provided, and from which, as required, they were removed through the ash-pit. In many cases a supply of steam was provided underneath and in front of the dead-plate, by means of a ¼in. or ⅜in. pipe, perforated with holes about $\frac{1}{32}$in. in diameter, and so drilled that jets of steam and air were blown along and between the line of the fire-bars, the effect of this minute expenditure of steam being to prevent the adhesion of clinker to the bars, and to act as an aid to combustion. Machine stokers of all kinds being fitted with hoppers which were filled by hand, in lieu of the coal being thrown direct into the furnace, there was no saving of labour, except as regarded slicing and raking the fires; but where there were several boilers in a range, the coal could be raised with a Jacob's ladder or elevator from the coal stock, and then conveyed in an overhead trough by a screw or tray chain to each hopper as required. The elevators and conveying screw were driven from a revolving shaft, which might be the one used for driving the machine stokers. Messrs. Coates, of Paisley, Messrs. Campbell of Perth, and other steam users in this country and in the colonies, who had adopted machine stoking, were also working these power conveyers with great success. In some cases this conveying plant was also employed to remove the ashes and clinkers. Machine stokers were generally worked by a small engine, a 6in. cylinder engine being ample for a range of twelve Lancashire boilers. The advantages claimed for machine stoking were:—

1. *Prevention of Smoke.*—The efficiency of a machine stoker as a smoke preventer was due to its "uniform careful firing." It was always working under Mr. C. Wye Williams' essential conditions of a "green" and a bright fire on the same grate, and much better localised than with "alternate-side firing," when it was possible for the gases to escape on the green side without combining with the oxygen on the hot side. With movable bars, machine stoking was at the least a greatly improved system of combustion, tending to smoke prevention. And, finally, one great cause of smoke was entirely absent—viz., the frequent use of the slice and poker to rouse the fire and clean the bars. An observer outside a mill where the boilers were hand-fired could count the firing and stoking times by the emission of smoke from the shaft. In machine stoking it was only at long intervals that the door was opened, and then for a much shorter time.

2. *Economy of Fuel.*—In the case of machine stoking this might result from two distinct causes. First, the

Digitized by Google

use of a cheaper coal, either too dirty for, or the heat units of which could not be fully utilised by, hand-firing. Secondly, the more perfect combustion due to a uniform supply of fuel, and the automatic and progressive manufacture of carbonic acid. With reference to the economy from the use of a cheaper coal than was possible with hand-firing, the testimony was overwhelming, and was rarely contested; but it was not so generally known that, owing to the more perfect combustion in machine stoking, the cheaper coal realised also a higher evaporative duty per pound of fuel.

3. *Machine Stoking.*—This gave an increased and more uniform evaporative duty; of this there was a large amount of evidence available. There were good reasons for anticipating a greater evaporative power with sprinkler than with coking stokers in certain cases. The automatic supply and progression of the fuel gave great uniformity of evaporation, while the mechanism employed afforded facilities for varying it as might be required.

4. *Economy of Labour.*—This might be and was realised by machine stoking, as the system permitted the automatic supply of fuel to the hoppers. In the mercantile steam navy machine stoking was hardly known, only a few vessels being fitted with Henderson's movable self-cleansing fire-bars. It would be an efficient remedy for many sea troubles, it would save the loss in cleaning the fires, and would give a larger increase of evaporation duty than forced combustion by fans, with much less inconvenience. An increased duty of at least 10 per cent. would be obtained from the fuel, and less skilled labour would be required. In addition to these advantages, all classes of cheap coal would be available for steamships, and smoke would be prevented.

The approximate number of furnaces fitted, and now working, with machine stokers was as followed:—

Coking.		
Juckes and others, old style	300	
Vicars.....	2,500	
Sinclair, McDougall, and others	600	
Frisbie, Beely, and others	200	
		3,600
Sprinklers.		
Stanley, beater, or fan machines	20	
Dillwyn, Smith, and Henderson	1,500	
Whittaker, Hodgkinson, Carver, Newton, Rye, Leech, and others	1,000	
		2,520
Spring Machines.		
Bennis	5,000	
Proctor	4,000	
		9,000
Total.....		15,120

This would represent about 8,000 boilers, out of an estimated total, in the United Kingdom, at the present time, of 140,000, or only 5·7 per cent. fitted with machine stokers, and it had taken nearly seventy years to achieve this limited success. It was estimated that, of the 140,000 boilers in the United Kingdom, about one-half were to be found in the three counties, Lancashire, Yorkshire, and Cheshire, and about the same number (70,000) were under inspection by the Manchester Steam Users' Association and the several boiler insurance companies. In two large boiler guarantee and insurance associations there were approximately 1,010 boilers fitted with machine stokers, or about 8 per cent. of the total number under the inspection of these associations.

CONSTRUCTIONS IN EARTHQUAKE COUNTRIES.

In one of our early numbers (see *Industries*, Vol. I., page 254) we directed the attention of our readers at considerable length to the conclusions arrived at by Professor John Milne, of Tokio, and given in a paper read before the Institution of Civil Engineers, regarding the conditions which should be attended to in constructions in earthquake countries. Professor Milne has for many years been a most diligent student of the phenomena of earthquakes and their effects, and is now one of the greatest, if not the greatest authority on the subject, and his writings contain a vast amount of information regarding it. He has carefully studied it in what may be considered its purely scientific aspects, but he has gone much beyond that and shown what lessons are to be derived with regard to construction in earthquake countries. In one of the recent volumes of the Transactions of the Institution of Civil Engineers (Vol. C., page 326) there is a paper by Professor Milne which may be looked upon as a continuation of the previous one, and it may be of use to some of our readers if we note a few of Professor Milne's chief conclusions. British enterprise extends to all parts of the world, and earthquake countries such as those of South America are receiving a considerable share of it, and the results of Professor Milne's observations and study will be found deserving the attention of all engaged in architectural or engineering construction in such countries.

The selection of a suitable site is the most important matter in connection with such construction, and in order to mitigate the effects of earthquakes the general conclusion at which Professor Milne arrives is that it is essential to select a site where it is known that the ground suffers but slight motion. This is generally hard, high ground. Soft ground, slopes, and scarps should be avoided. A site being selected, one of two general systems of construction can be followed, namely, either to give so much rigidity to a structure that it may be likened to a steel box; or to erect a light building, which has so much flexibility that it may be compared to a wicker basket. Both those structures should be light, especially their upper parts. Buildings of the former class, which are generally of stone or brick (by preference hollow bricks) should rise from a deep foundation, have a free basement, walls of unusual thickness, and be well bonded and tied together. The roofs should be light, and the precautions respecting the position and form of the openings, the arrangement of floors, roof trusses, and top weight should be carefully attended to. In buildings of this kind, their strength more than outweighs the ill effects due to their weight. Such buildings are durable and relatively safe against fire. They are suitable for all climates, but they are in respect to all other buildings exceedingly expensive, and therefore can only be employed for buildings of importance. Light buildings are nearly all constructed of wood or iron. The former, however, are neither durable, safe against fire, nor impervious to heat and cold, but these objections may be practically overcome. They have, however, the advantage of being cheap. Iron buildings are relatively expensive, and, without special arrangements, they are too hot in summer and too cold in winter. Framed buildings of iron or wood, filled in with hollow bricks or cement, such as are so strongly recommended in Italy, have many advantages, and modifications of them are much used in Japan. In buildings of all kinds the roof must be light, openings must be in proper positions, walls must be of moderate height, while floors, trusses, balconies, and the like must be well supported. Ordinary structures of brick or stone are usually bad, while timber structures with a masonry front are worse. To resist earthquake motion, lightness and strength are essential, and so is a certain elasticity. Weight, unless

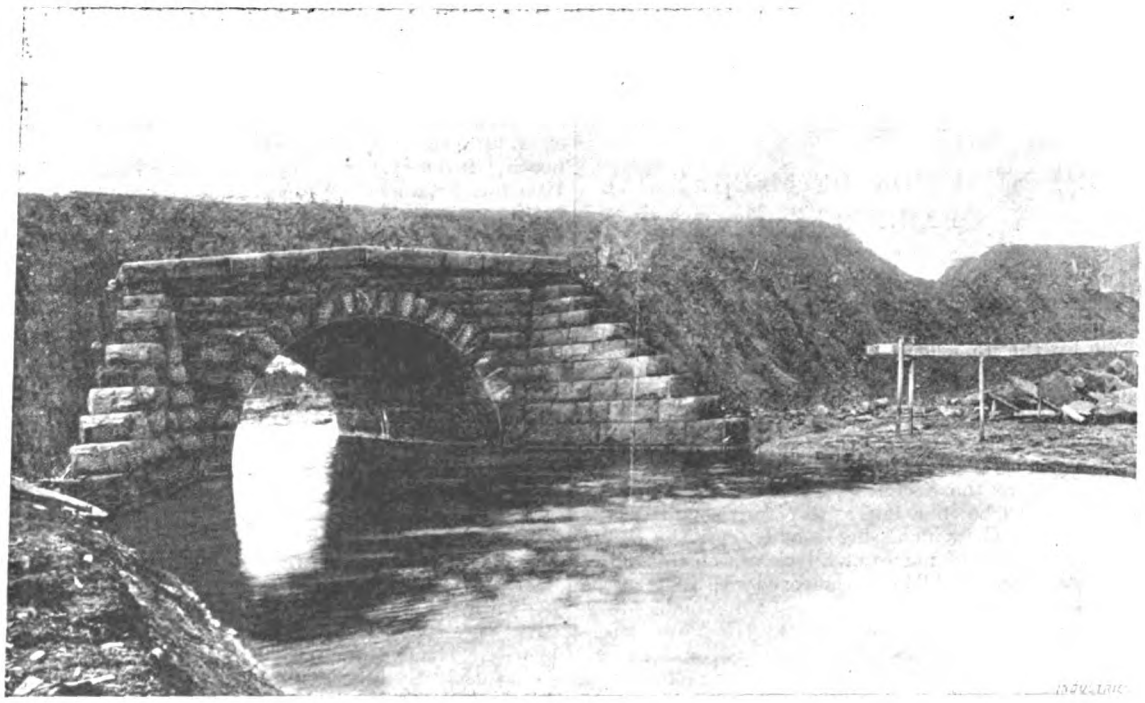

Fig. 9.—Showing the Culvert for the Tidnish River Diversion.

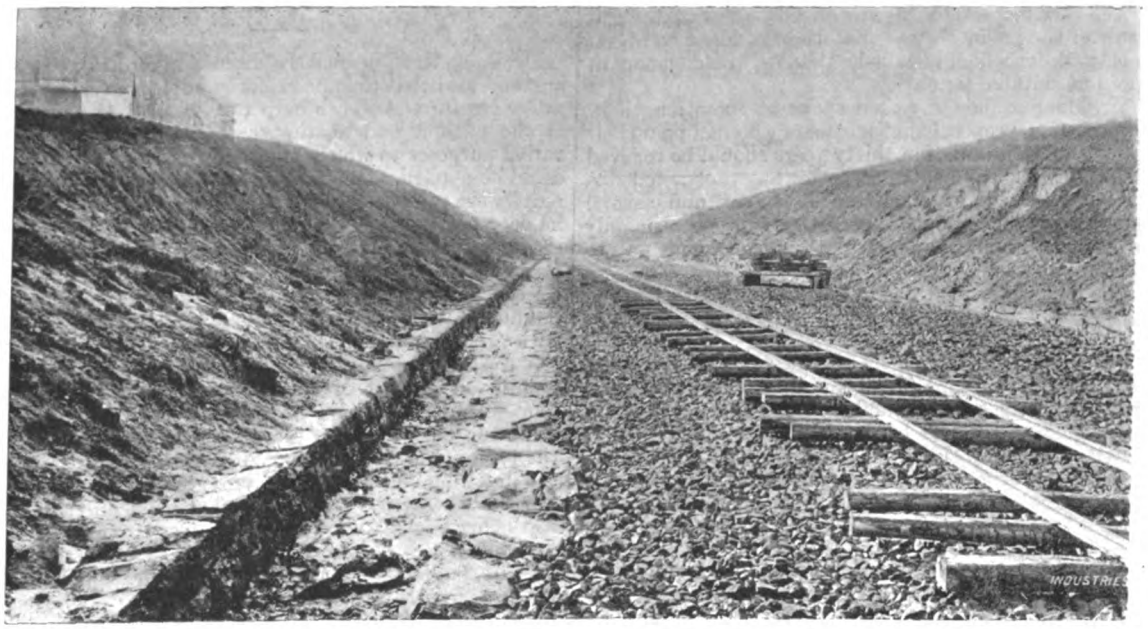

Fig. 10.—The Completed Cutting at Tidnish.

Digitized by Google

it is accompanied by great strength, is a quality to be avoided.

For buildings of importance Professor Milne suggests the use of brick, and as regards this opinion considerable experience in earthquake countries enables us to corroborate his suggestion. The buildings should be in good situations, the brickwork well bonded and unusually thick, and rise from deep foundations. For ordinary buildings he suggests that, for a country like Japan, frame buildings should continue to be used. To improve them, they require more diagonal bracing, lighter roofs, and some protecting covering against fire.

THE INSTITUTION OF MECHANICAL ENGINEERS.

The forty-fourth annual general meeting of this Institution was held on Thursday evening, the 29th ult., and continued on Friday evening. The chair was taken by the President, Mr. Joseph Tomlinson. On Thursday evening, after reading the minutes of the previous meeting, the Secretary announced that the summer meeting would be held in Liverpool at the end of July. The usual annual report of the Council was presented to the members, a brief verbal abstract of the same being given by the Secretary. This report shows the Institution to be in a fairly prosperous condition, the number of members increasing steadily. At the end of 1890 the number of names of all classes on the roll of the Institution was 1,945, as compared with 1,858 at the end of the previous year, showing a net gain of 87. Among the new members is included His Royal Highness the Prince of Wales, who was elected an honorary life member at the spring meeting. The Institution lost by death during the past year eighteen members. The receipts during the year amounted to £6,784 16s. 5d., and the expenditure to £5,738 6s. 2d., leaving a balance of £1,046 10s. 3d. After allowing for accounts owing but not yet rendered, the capital of the Institution stands at the very respectable figure of £33,708 4s. 9d. The result of the ballot showed that the President had been re-elected, for which honour he thanked the members in brief but suitable terms.

Mr. MacFarlane Gray then spoke at some length in support of a proposal that members who had paid their annual subscriptions for thirty years should be relieved of all further payments. A somewhat protracted discussion followed, in which the President and several members of Council opposed Mr. Gray's proposal, mainly on financial grounds, and, on the question being put to the vote, it was negatived.

The first paper read was by Mr. Bernard Dawson,

"On Some Different Kinds of Gas Furnaces."

This paper was of a generally descriptive character, accompanied by a large number of diagrams. The author stated that the greater number of gas furnaces in which crude heating gas had been successfully employed were of the kind now universally known as reversing regenerative furnaces. There were, however, many processes, in which temperatures below that which could be maintained only by "Siemens regenerators" were required, for which gas furnaces could be employed with some success, both as regards economy in quantity and quality of fuel, speed of work, saving in wear and tear, labour, abolition of smoke, and certainty in maintaining an atmosphere or flame of a given character. It was often, also, an advantage in large works to concentrate in one place the manipulation of all the fuel required in the various furnaces scattered throughout the establishment, and avoid the cleaning of fires and removal of ashes. There was thus often a distinct advantage in using gas for heating furnaces apart from economy in fuel. Reversing regenerators were only economical and advisable for high temperatures, but there was some diversity of opinion as to the exact point at which such regenerators could be advantageously dispensed with. Whatever system of regenerator might be adopted, care must always be taken to ensure that the escaping gases should pass into the chimney flues at a sufficiently high temperature to secure the draught requisite to work the furnace advantageously. Gas furnaces might be divided into four classes—(*a*) With reversing regeneration, (*b*) with continuous regeneration, (*c*) non-regenerative, and (*d*) with blow-pipe or forced blast.

The author then proceeded to describe, with the aid of numerous diagrams, types of furnaces belonging to each class. The well-known ordinary Siemens furnace is representative of the first class (*a*), which also includes the Batho or Hilton furnace, with regenerators encased in cylindrical wrought-iron vessels above ground; furnaces in which the air only is regenerated; and the furnace recently described by Mr. Head (*Iron and Steel Institute Journal*, 1889, II., page 256), in which a portion of the waste heat is taken back to the gas producer. In furnaces with continuous regeneration the air, before admission to the interior of the furnace, is heated by radiation or conduction from the bottom of the furnace, and through thin walls separating the air flues from the flues carrying the waste heat to the chimney. In non-regenerative furnaces the air is admitted to the furnace at its natural or atmospheric temperature. In forced blast or blow-pipe furnaces the air is either supplied at atmospheric temperature by a fan or blower, or air thus supplied is heated by the waste heat from the furnace, as in the Radcliffe furnace.

Among the varieties of gas furnaces referred to by the author the following may be mentioned:—Crucible steel furnaces, basic and ordinary steel furnaces, reheating furnaces, bar and tire heating furnaces, glass tank furnace, annealing furnaces, sand-drying or calcining furnace, core and mould stoves, gas-fired oil boiler or still, gas-fired brewer's copper, and gas-fired Babcock & Wilcox and Lancashire boilers. The author also dealt with the construction of reversing valves for regenerative furnaces. The butterfly valve was being superseded by "pot" or double-beat mushroom or pan valves, and also by the hydraulic slide valves of Mr. Le Neve Foster, water-seated valves, and Mr. John Ramsbottom's revolving valve. A brief notice of the application of water gas to heating purposes, and a description of the Smith Casson open-hearth steel-melting furnace were included in the paper. We have alluded to these in particular, because they were afterwards referred to in the discussion.

Mr. J. A. F. Aspinall, in opening the discussion on Mr. Dawson's paper, referred to the gas furnaces at Horwich Works. The gas furnaces used there for brass melting had been, he said, generally successful, but in the application of gas fuel to steam boilers the results varied greatly. His experience went to show that where boilers were sufficiently large for their work gas firing gave satisfactory results.

Mr. J. M. Dobson inquired whether the conveyance of gas for a long distance was a drawback to its use.

At the termination of Mr. Dobson's remarks the discussion was adjourned till the following evening.

Mr. John Head opened the discussion on Friday evening, and said that the numerous examples of the regenerative gas furnace shown bore testimony to the activity of the author, and at the same time illustrated the varied purposes to which the Siemens form of furnace could be applied. According to his experience, gas furnaces were rarely erected except for economy in fuel, and he deprecated passing waste heat into the chimney for creating a draught. For securing sufficient draught for a furnace, the height of the chimney should be raised. A furnace with a bed supported on girders could be built without having recourse to the forms shown with regenerators built in boxes either at the sides or on the top of the bed. The latter were defective from a philosophical point of view, inasmuch as heat always tended to rise to the top of the chamber in which it was confined; hence regenerators should be vertical, so that the top of each chamber should be the hottest part, and the inflowing currents should enter at the bottom to be gradually heated as they reached the top on their way to the heating chamber. Fireclay pipes for regenerators are objectionable, as they may break, in which case the current that is being heated will pass up the chimney without reaching the furnace. All regenerative gas furnaces should be constructed so as fully to utilise the waste heat escaping from the heating chamber. In an open-hearth steel melting furnace of the ordinary Siemens type, making charges of twenty tons, the weight of the gases passing through the furnace in five minutes' time amounted to one ton; those gases deposited heat in the regenerators according to their temperature and their weight, and the inflowing gases must be of the same weight, and at a temperature not exceeding the waste gases, as they leave the reversing valves, in order to be able to take up the heat deposited. The only exception which could be allowed to this rule was in the case of the new Siemens furnace (of which diagrams were exhibited), wherein the gas producer utilised—in another manner—the heat that would otherwise be deposited in the gas regenerators. Mr. Head explained how heat was utilised in converting carbonic acid into carbonic oxide, thus, he said, saving one-half the carbon in the coal. The final result showed a saving of, say, one-third the coal used, to which should be added a further saving of the sensible heat of the gases amounting to 30 per cent., making together a saving of above 60 per cent. in fuel in favour of the new, over the old, Siemens furnace. In practice these results had been fully realised, so that now from fifty to sixty furnaces were either working or in course of construction. Beyond the results shown, he would only add the results of working of a large heating furnace, as ascertained during thirty-six hours' continuous work; in that time 210 tons of steel were heated, being at the rate of 70 tons per shift, and the consumption of fuel was only 1 cwt. of coal per ton of steel heated. The late Mr. Holley, the eminent American engineer, strongly advocated the use of the Siemens furnace, but the cost of the original form was sometimes found to be an objection to its introduction in many works. The new form of Siemens furnace was well suited to fulfil Mr. Holley's prophecy, referred to in the paper under discussion, as it effects a saving of 50 per cent. in cost of construction; also a saving of 50 per cent. of fuel, in working, over the original form.

Mr. Smith Casson stated that he would not go so far as to say that he preferred overhead to underground regenerators; the construction to be adopted was to a great extent a matter of convenience. Their practical success had, however, proved that overhead regenerators were not to be objected to. With his 6-ton furnace an average production of 65 tons per week was obtained, and no extraordinary difficulty experienced with the overhead regenerators. The number of casts per week was from twelve to fourteen, and about 11 cwt. of screened fuel was required per ton of steel. Where space was of value overhead regulators were to be recommended. With a small furnace producing only 2 tons per week satisfactory results had been obtained. In this case a great advantage was secured by placing the boilers overhead and utilising the waste heat to work them. In reply to a supplementary inquiry by Mr. John Head, as to whether the steel was made by decarburising pig iron with iron ore, or was simply an alloy of pig with wrought iron, Mr. Casson stated that he did not use iron ore.

Mr. Alfred Slater said that at the works with which he was connected a new Siemens heating surface had been erected only within the last two months, and, consequently, his experience was as yet very limited. Owing to a mistake on his own part the furnace had been under repair during some portion of this time, and, therefore, he could not give statistics. He had, however, no hesitation in saying that very appreciable comparative economy had been obtained by the adoption of the new furnace. For some reason, which he was unable to explain, after successfully employing for some time a certain kind of coal from the Forest of Dean, it had been suddenly found necessary to change the quality of the fuel.

Mr. Oakman remarked that his special work related to water gas and the other gases obtained in its manufacture. Since reading his paper in July, he had made good progress in the Sheffield district, and subsequent experience had more than confirmed his previous statements. By the application of water gas to welding an economy of about 40 per cent., as compared with coke firing, had been obtained. For continuous firing with producer gas, the gas was supplied under a pressure of about 3in. of water. Perfect control was secured, and the heat with producer gas alone could be varied from 800° to 2,000°. Arrangements had at one time been made for working with mixed water and producer gas, but had not been used, as it had been found that the mixing of the gases was not economical. Water gas should be employed where great heat was required, and producer gas for lower temperatures. On the Continent and in the United States water gas was being used for open-hearth furnaces with success. In a 6-ton furnace a ton of steel could be produced with 6 cwt. of fuel, while the cost of the furnace did not exceed £120. If he might venture to prophesy, he would say that the time was not far distant when both gas and air would be used under pressure.

Mr. Reed inquired whether the author could give the temperatures reached in gas furnaces, and what pyrometers he had found to give the best results. With respect to the gas firing of boilers, he was interested in an arrangement, invented in the United States and now at work in this country, which was characterised by great simplicity. The gas generators consisted of two cast-iron retorts behind a brick arch; steam was supplied to the retorts through a small pipe from the steam dome. The ashpit was closed, except to the injector carrying in gas and air. This arrangement had only been at work a short time, but the results shown by a week's trial had been very astonishing, the saving effected amounting to 38 per cent. In reply to a question by Mr. Druitt Halpin as to the previous performance of the boiler referred to, more especially the quantity of water evaporated per pound of fuel, the speaker said that he was unable to state this; the comparison was of a purely practical character.

Mr. MacFarlane Gray pointed out that, by means of the device described by Mr. Reed, steam was dissociated into its constituent gases, which were reunited afterwards by combustion in the furnace.

Mr. Drew described a stationary boiler installation at Glasgow, in which the air supplied by a fan was heated by the waste gases before entering the furnace, the result being a reduction of 30 per cent. in the consumption of fuel. This was simply an application to a stationary boiler of Mr. Howden's system of forced draught, hitherto

Digitized by Google

adopted only for marine boilers, and he (the speaker) mentioned it simply to show what scope there was for saving.

Mr. Schönheyder wished to know what was the temperature of the waste gases in the boiler in question; it must have been enormous to make a saving of 30 per cent. possible.

Mr. Drew was unable to give this information off-hand, but promised to furnish it subsequently.

Mr. H. Marten stated that he had considerable experience with boilers fired by the waste gases from blast furnaces, but not with such in which the gas was made for the purpose. The first speaker had said that gas firing damaged boilers when they were worked hard. He would like to know to what this was due. Was it owing to the nature of the gases or some other cause? The difficulty he had found with blast furnace gases was the extreme variation in their temperature and excessive local heating of the boilers, one part being very hot, while another was comparatively quite cool. His boilers were very long ones.

Mr. Collier asked the author for further information on the application of gas to the heating of brewers' coppers, more especially in regard to economy. His experience was that, unless the lower part of the copper was well protected at the edges, it was soon burned away. He would also be glad to learn what saving was effected by the use of gas in connection with Babcock and Wilcox, and Lancashire boilers, as shown in two of the diagrams, Nos. 19 and 20.

Professor A. B. Kennedy remarked that it was an interesting feature of the new Siemens furnaces that the gas for them was supplied hot. He was under the impression that formerly, in the older types of furnace, it was always thought desirable to allow carbonic oxide gas to cool before entering the furnace. He thought it desirable to draw attention to the fact that the successful use of gaseous fuel in furnaces had no bearing on its employment in ordinary boilers, as the conditions were so different in the two cases. In furnaces it was necessary to obtain a very high temperature, and for this purpose it was necessary that the gases should escape at a high temperature. In consequence of this a regenerator was essential to economy. In steam boilers the case was just the opposite; the temperature required was comparatively low, and in good boilers efficiencies of over 80 per cent. had been achieved without the use of regenerators. If heating furnaces were employed without regenerators, the efficiency would be absurdly low. Success in one case was no proof of success in the other, and he believed that the failure to appreciate this fact had resulted and would result in disappointment.

Mr. H. Marten remarked that the interest on the cost of plant necessary for burning gas in boilers neutralised the saving in fuel.

Mr. Snelus said that one of the valves mentioned in the paper was designed by his pupil, Mr. Foster; this was a slide valve. Butterfly valves gave much trouble; they leaked, were liable to warp, and could not be easily inspected. To Mr. Foster's valve he had added a cooling device to prevent warping. There was only one small objection to it, and that was a slight deposit of tar when the valve was not in use; when in operation no trouble was experienced. Double beat valves were fairly good, but it was difficult to make certain of their being fully down on their seats; in this respect slide valves were better if properly cooled. Mr. Snelus noticed that the author had not mentioned in his paper the American Lash furnace. This was worked in the United States with natural gas. The regenerators were placed at right angles to the furnace on the way to the flues, an arrangement which to him was novel. At Mr. Carnegie's works he had seen such furnaces in operation, and they gave very satisfactory results.

Mr. Halpin inquired whether reversing regenerators had been tried for steam boilers.

Mr. Bernard Dawson, in reply to the discussion, stated, with regard to the remarks of Mr. Aspinall and Mr. Dobson, that in practice he had not found that the conveyance of gas for some distance was any drawback to its use. For supplying producers with steam it was the best plan to employ a small separate boiler in order to avoid the irregularities caused by fluctuations in the main boilers. He had never before heard the objection raised that a boiler could not be forced when fired with gas. Such a state of things could only be due to defective arrangements. In some dyeworks in London with which he was acquainted, in which gaseous fuel was burned, the boilers were frequently forced. He thought there was conclusive evidence that gas fired boilers gave better results than those burning solid fuel. Respecting Mr. John Head's criticisms, the author said that he considered a record of failures was particularly instructive to engineers, and often more was to be learnt from them than from successes. All Siemens furnaces, he believed, had not been uniformly successful. There were many cases in which it was worth while to adopt gas firing even when it was not more economical than other methods, for reasons to which he had referred in his paper. The Radcliffe furnace, he had been assured by the authorities at Woolwich, gave no trouble on account of the leakage of brick tubes. As regards Mr. Smith Casson's remarks, all regenerators placed below the furnaces were liable to become silted up with lime in basic furnaces and with slag in ordinary Siemens furnaces, but this could not occur with overhead regenerators. Replying to Mr. Reed, the author said that he had never yet found a satisfactory pyrometer. All of which he had experience could be "cooked" to indicate whatever was desired; they never returned to zero, and required continual correction of the constants. Gas firing for boilers was not such a novelty as Mr. Marten seemed to suppose; there were hundreds of such boilers in use. With reference to Mr. Halpin's inquiry, he (the author) had carried out some experiments on coal and gas firing with a boiler of the locomotive type, with and without the brick arch. With small common South Wales coal the best result observed was an evaporation of 8¾lb. of steam per pound of fuel. In a "Roots" boiler he had found an advantage of 17 per cent. with gas over coal firing. The best result he had ever obtained with gas firing was 11½lb. of steam per pound of coal. When boilers were fired with gas specially made for the purpose and with proper arrangements, there were no irregularities in the heat, such as those complained of by Mr. Marten. These irregularities were probably partly due to the length of the boilers. Those brewers' coppers which had been heated by gas and furnished with regenerators had been quite successful. To Professor Kennedy his thanks were due for pointing out in such a lucid manner the distinction between heating and boiler furnaces. As to the Lash furnace mentioned by Mr. Snelus, he had been unable to get information about it from the United States. The use of horizontal regenerators, as described by Mr. Snelus, was not new; such regenerators he had seen in connection with the horse-shoe type of furnace. The expense of adopting reversing regenerators for boilers, as suggested by Mr. Halpin, was not justified by the results.

The next and final paper read was by Mr. Walter Bagshaw, of Batley,

"On the Mechanical Treatment of Moulding Sand."

After some brief introductory remarks, the author commenced by describing the qualifications necessary for good moulding sand. This part of his subject he illustrated by diagrams, showing samples of sand, mixed sand and coal dust, and old and burnt moulding sand, magnified 500 diameters. Generally stated, good sand should be composed of 94 parts silica, 5 parts alumina, and traces of magnesia and oxide of iron. For facing sand various mixtures were employed. Plumbago was effective in preventing the destruction of sand, but should not be dusted on the moulds in such quantities as to close the pores and prevent free exit of the gases. The most primitive method of treating moulding sand was by hand riddling and treading. No doubt tough sand could be obtained in this manner, but the process was tedious and, on a large scale, expensive. Other things being equal, the chief characteristics of good moulding sand were toughness and porosity. Power riddling was a decided advance on hand riddling, but presented the objection of not opening out the grains. For hard sand treatment by means of the roller mill was said to answer very well, but the author's experience with soft sand had not been favourable to rolling, the castings made with sand so treated showing a tendency to scab. Schütze's centrifugal mixer, of which the author exhibited illustrations, combined the advantages of all the other plans, besides yielding a greater output. It consisted of a revolving table mounted on the top of a vertical spindle, and carrying on its upper face a number of vertical pins or beaters fixed alternately in a series of concentric circles. The table has a hinged cover, which can be opened for the purpose of removing pieces of metal or other foreign substances. The sand falls upon the centre of the table, which revolves at a speed of 1,200 revolutions per minute, from a hopper above, and is projected with great velocity from one row of pins to the next, until all had been combed out. At a moderate estimate, such a machine would mix 30 tons of sand per diem. One in use in Devonport Dockyard required 1 horse-power when mixing 2 tons per hour. The cost was about 2d. per ton of sand. Messrs. Marshall, Sons, & Co., of Gainsborough, employed three men on one machine to mix sand for 150 moulders and fourteen moulding machines, but expected eventually to reduce this to one man's work. With hand-riddling and treading, the average cost was about 2s. 1d. per ton for wages alone, and, with machine riddling, 1s. 3d. per ton. After working for two years with the mixer, no expense of any kind had been incurred for repairs.

Mr. Schönheyder opened the discussion by suggesting that it would add to the value of the paper if the magnified illustrations of moulding sand, when published in the "Proceedings," were coloured.

Mr. Mair said that in the old days they had only hand mixing. He had found that ordinary roller mills made the sand too dense, and had substituted serrated rollers for plain ones with good results. One point in favour of plumbago for facing had been omitted by the author, which was that it enabled castings to be more readily cleaned. In the United States he had seen very long cores made without wires, a very strong core gum being used to secure adhesion. The grains of the sand employed for such cores were nearly $\frac{1}{16}$in. diameter.

Mr. Brown inquired whether, with the aid of a mixing machine, a large proportion of floor sand could be used for facing.

Mr. Wilson stated that he had seen one of Schütze's mixers in operation at Mr. Cochrane's works; it had given great satisfaction, but it had been found that, contrary to the author's experience, the wear was very considerable and irregular.

The Secretary then read a letter from Mr. Cochrane (who was unable to attend the meeting), in which he wrote that he had had a Schütze machine in use for many months, and it gave unqualified satisfaction. The output was as high as one ton in five minutes. Previous to the introduction of the machine four men, at a cost of 11s. 6d. per diem, had been required to supply fifty moulders, but now the whole of these, and the coremakers as well, were supplied for 6s. per diem. This reduction in expenditure was accompanied by an improvement in the quality of the work. The expenses of the machine were insignificant. On one point he disagreed with the author; there was no prospect whatever of the wrought-iron pins or beaters standing for two years—in fact, some of them were reduced to $\frac{1}{2}$in. in three weeks working only half time. The manner in which the wear took place was very curious, certain pins being worn much more rapidly than the rest, as though the sand followed certain relative courses in preference to any other. In his machine the arrangement of the beaters was not exactly as described by the author, in concentric circles, but apparently quite unsystematic. There was one drawback to the machine, and this was, that it could not be stopped quickly; in this respect, he thought, there was room for improvement by the addition of a brake. Otherwise, the apparatus could be generally recommended.

In replying to the discussion, Mr. Bagshaw confirmed the statements made in his paper with reference to the wear of the pins or beaters. The pin exhibited to the meeting, which was very slightly worn, was the worst he could find after the machine had been at work for three years. As to stopping quickly, he could only say that the man in charge of his machine preferred to run it without a brake, as, when the latter was applied, the driving belt flew off.

THE INSTITUTE OF MARINE ENGINEERS.

A meeting of this Institute was held on the 27th ult., Mr. F. W. Wymer presiding. The paper read by Mr. F. W. Shorey at the previous meeting was further discussed. The chief point of novelty in the paper was a proposed system of "profit sharing," and the leading feature of the arrangement was one to ensure that each man should do his best for the success of the business in which he was engaged, if this could be done without cumbrous inspection.

Previous to the discussion on the above paper, a conference was held by the members of Council and a deputation of members from the Bristol and South Wales, consisting of Professor Elliot and others. Professor Elliot explained the purpose of the meeting, and hoped for an opportunity to welcome the members to Cardiff. Mr. MacFarlane Gray reported that he had heard some flattering remarks regarding the Institute of Marine Engineers as a whole, and on the discussions on the various papers which had been reported in the technical journals.

The annual general meeting of the Institute will take place on the 3rd April, when some important matters will be discussed.

ELECTRIC LIGHTING IN JAPAN.

The first electric light company in Japan was formed at Tokio in 1886. With the lighting of the Imperial Palace an important advance was made in the industry, and since then other companies have been formed at Osaka, Kioto, Nagoya, and Kobe. It is estimated that there are now 11,000,000 electric lamps in the country, and of this number 8,000,000 are at Tokio alone. The capacity of the present five companies is rated at double the above number. No less than ten further electric light companies, says the *Railroad Gazette*, are at present being organised. They will have a combined capacity of 16,000,000 lamps, of which 5,000,000 will be placed at Yohohama.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 3rd February, 1891.

Iron.—The depression in the iron market still continues, but there is an inclination to greater activity. The prices at which business has been transacted remain the same as those of last week—namely, 128s. 6d. a ton for bars and 136s. 6d. a ton for joists. Sheets command from 152s. 6d. to 160s. a ton according to quality, but the demand has been very limited during the past week for all descriptions of iron. The Town Council (*le Conseil Municipal*) have authorised the Orleans Railway Company to prolong the line running to Sceaux and Limours into Paris as far as the Place de Medicis, near the Luxembourg. The station at this point has been commenced, and will be in many respects similar to the London Metropolitan stations, all this extension being underground, The same company contemplate a further prolongation of this line under Paris as far as the terminus of the Orleans main line near the Jardin des Plantes. The Western Railway Company are about to construct a line connecting Havre with Dieppe.

Copper, Tin, Lead, Zinc.—The situation remains unchanged in the copper market, though with a slightly weaker tendency. The tin market shows a rise in Billiton and Banca brands, which have gone up 10s. a ton. Leads of all classes have fallen off 4s. a ton, and generally throughout France business is very dull in this article. Zinc continues firm, with a tendency to a rise in price.

French Commerce.—The following statistics are taken from the report of the Customs Administration (*L'Administration des Douanes*) for the year 1890. The total imports between the 1st of January and the 31st of December are put down at 4,423,255,000fr., and the exports at 3,720,121,000fr. In nearly all sections the figures show a marked increase on the year 1889, but the exportation of raw material is more than 65,000,000fr. below that of the preceding year, while the importation of the same shows an increase of nearly 29,000,000fr., from which it may be inferred that French industries are rapidly growing.

BERLIN, 2nd February, 1891.

Electrical Exhibition in Frankfort.—At a recent meeting of the Frankfort Electrical Association, it was stated by Herr O. von Miller that the proposed Exhibition is to be strictly divided into separate sections. The section which is to be devoted to electrical railways and signalling will be chiefly occupied by four electrical railways, worked either by accumulators, or by overhead or underground conductors. In the section devoted to telephony and telegraphy, Messrs. Siemens & Halske exhibit an exchange instrument for the sending of telegrams from a central office by means of type recording instruments in the houses of customers. In the section of electrolysis, there is to be a complete collection of aluminium articles made by the Neuhausen Company, including a petroleum launch made of aluminium. With regard to the electrical transmission of power, the Exhibition will receive 100 h.p. from the palm garden, 100 h.p. from Offenbach, and 100 h.p. from Lauffen-on-the-Neckar. Messrs. Siemens Brothers are laying down a cable which is said to be for a current of 20,000 volts.

The McKinley Bill.—To give a clear idea of the effect of the McKinley Bill concerning the export of woven goods from Chemnitz to the United States, the following synopsis for the last quarter of 1890 and 1889 will be useful. The export amounted in the fourth quarter in—

	1889.		1890.
Cotton gloves	$163,610	...	$115,533
Silk gloves	271,264	...	136,855
Woollen gloves	47,464	...	11,268
Cotton hosiery	1,757,436	...	1,169,890
Silk hosiery	74,036	...	34,617
Woollen hosiery	19,783	...	11,932
Jersey material	15,801	...	—
Tricot goods	25,435	...	32,109

German Wood Trade in 1890.—According to the annual report of the Union of German Wood and Wood-Floating, the wood trade of the year 1890 was exceedingly brisk. Into the harbour of safety, Brakemünde, there were floated, from the Vistula, 925,000 running metre rafts, 4 metres wide, as compared with 928,345 in the year 1889, 815,045 in 1888, and 619,512 in 1887. Through the Canal of Bromberg were floated in 1890 957,624 m., as compared with 849,217 in 1889, 741,174 in 1888, and 669,368 in 1887.

Trial Trip.—The new fish steamer "Fock and Hubert," which has been built in the shipbuilding yard of Chr. Jürgens & Co., Steinwärder, by order of the Fish Steamer Company in Cranz, has recently made its maiden trip, which was very successful. The "Fock and Hubert" is the first steamer for high sea fishing built in Hamburg. Only German steel has been used for its construction. The engines are built on the compound system, and provided with surface condensation. They indicate 300 horse-power.

VIENNA, 2nd February, 1891.

The Iron Market.—The expectation of a good building season next spring has caused a brisker tendency in the iron market. Important orders have been given for bar iron and thick plates, which will help to maintain prices. The interruption of the railway traffic has caused stagnation in business with regard to hardware and machinery. The Kaschau-Oderberg Railway has given an order for 500,000kgr. of Bessemer steel rails, and for a large quantity of other iron materials.

The Coal Market.—The Vienna coal market has recently been in a miserable condition. The stagnation of the railway traffic has hindered the forwarding of coal from the snow-covered districts. The Northern Railway had great difficulty in dealing with 200,000 cwt., though the usual traffic is from 1,300,000 cwt. to 1,400,000 cwt. The demands of the various coal consuming industries were, therefore, only partially satisfied. On the 29th ult. the stagnation of the traffic was relieved, and the trade of the Vienna coal market became normal. In the Bohemian coal region also the weather has caused much difficulty, but during the past few days the traffic has again become regular. The regularity of railway traffic is the more important, since traffic by water is at a standstill.

Electrical Engineering.—The electrical machinery which is being installed in the new residence of the Empress at Corfu by the International Electricity Company consists of an electric light installation, of a condenser for the production of fresh water, of a refrigerating machine, and of a telephone installation. For the purposes of the electric lighting installation there are three steam boilers, which have been obtained from the manufactory of Messrs. Sigl in Vienna Neustadt, a steam engine from the same makers, and two dynamos of the type Δ 3, constructed by Messrs. Ganz & Co., of Budapest. The telephones are supplied by the Vienna Private Telephone Company. The whole of the plant is to be in working order in the autumn of this year.—The General Austrian Electricity Company has been formed during the past week. Hofrath von Hauffe, the President of the Association of Engineers and Architects, has been chosen as the President of the administration. The other members are the representatives of the Anglo-Austrian Bank and of the firm of Messrs. Siemens & Halske.—A short time ago the "Kleinmünchner" spinning factory began to be driven by the electrical transmission of power supplied by its own water power. The electrical installation was provided by the Oërlikon Company.—The Innsbruck Central Station of Messrs. Ganz & Co. has been considerably enlarged. The largest installation which is supplied from this station is the Jesuits' Church, which is lighted with 1,000 lamps of 16 candle-power.

DÜSSELDORF, 3rd February, 1891.

Iron and Steel Market.—The pig iron market is fairly quiet. The steel works generally are in full operation, but plate and wire makers are seeking orders. Siegen sheets are at from 130 to 145 marks. The builders of railway waggons are hopeful for the future, as the rolling stock of the Prussian State Railways is not sufficient for the existing heavy traffic.

Coal Market.—The production of coal in the Oberbergamts district, Dortmund, was, in the first quarter, 9,032,158 metrical tons; second quarter, 8,526,636; third quarter, 8,977,021; and fourth quarter, 9,032,773—total, 35,568,588 metrical tons. As the production in the same period of the previous year was 33,851,190 tons, the increase is 1,717,898 tons, or 5 per cent. The number of miners at the close of 1890 was 132,038, against 121,200 in 1889, or 10,838 more men, an increase of about 9 per cent. These figures prove that the tonnage produced by each man has diminished. There is still a great deficiency in coal waggons, and in the Ruhr district this deficiency amounted on several days to upwards of 4,000 waggons. Prices are strong in spite of the mild weather, which commenced a week ago, as the severe weather continued longer on the Upper Rhine than on the lower part. The ice, which at some places had a thickness of 15ft. to 20ft., has done less damage than was expected. The Upper Rhine from Loreley to Bacharach is still frozen.

English and Westphalian Coal in Hamburg.—The coal consumption of Hamburg in the past nine years is shown in the following table, in which the tons = 1,000kg.:—

	Westphalian Coal. Tons.		English Coal. Tons.
1882	494,994	...	1,015,400
1883	530,720	...	1,043,800
1884	562,673	...	1,025,500
1885	553,970	...	1,138,700
1886	572,945	...	1,206,700
1887	613,110	...	1,227,820
1888	715,720	...	1,365,000
1889	817,836	...	1,585,531
1890	885,882	...	1,582,900

Though the import of English coal has grown steadily, the Westphalian coal shows an increasing percentage of the whole consumption.

Cement Market.—The prospects of this branch of business are not bright. In the Silesian manufactories the price which is now asked for each keg of 175 kilogrammes is 5·40 marks, whereas in the past year the price was from 6·60 to 6·80 marks. During the present season the shipment of cement is of course small. It is expected that there will be a demand for cement for the building of fortifications, and that a supply of 40,000 tons will be needed for the Nordostsee Canal.

Dr. Otto.—On the 26th ult. there died at Cologne, after a brief illness, a man of considerable eminence, Dr. Nicol August Otto, the inventor and patentee of the well-known "Otto" gas engines. Some twenty-five years ago his attention was drawn to gas engines, and in connection with Mr. Eugene Langen he brought out an engine, called "Langen and Otto's atmospheric gas engine," which attracted considerable attention for some years. This engine was open to many objections, but was highly economical and extremely ingenious. Subsequently he invented the "Otto" gas engine, which found such great favour that in a short time he was enabled to appoint makers all over the world, from whom he derived very large royalties. As an inventor, Dr. Otto possessed inexhaustible patience and considerable fertility of resource. Though he was not brought up as an engineer, he soon became one, as he had great mechanical talent and theoretical knowledge.

AMSTERDAM, 2nd February, 1891.

The North Sea Canal.—An important discussion has taken place in the Town Hall, under the auspices of the Society for the Promotion of Shipping Interests in Holland. The subject was the recent closing of the port of this city by the freezing of the North Sea Canal, and the report was read of the special committee appointed to remedy the ice blockade and to devise means for preventing a similar predicament, so disastrous to shipping and trade, in the future. The report says that it is not impossible to keep the North Sea Canal open at all times of the year, but such an expensive effort should not be undertaken by the trading community alone. The State, the province, and the town of Amsterdam should each be asked to contribute their quota. In the course of an interesting discussion which followed the reading of the report, it was pointed out that the port and town authorities in other places consider it part of their duty to ensure free access even in the severest of winters to all vessels, whilst in Amsterdam the task is left to private enterprise. It was also contended that the State should take some action, in the interest both of the country's trade and navigation, and also in that of the national defence. The meeting finally adopted resolutions in favour of the committee's report. This involves an expenditure of nearly £4,000, spent in clearing the North Sea Canal of ice during the late frost, and authorises the committee to open up negotiations with the State, the province of North Holland, the town of Amsterdam, and the leading houses interested, for obtaining a fund of half a million guilders. The interest thereon, computed at £5,000 per annum, is to be devoted to the maintenance of an efficient ice service upon the North Sea Canal.

Navigation at Amsterdam.—Unofficial statistics show that 1,675 vessels, with a capacity of 4,200,409 cubic metres, entered the port of Amsterdam in 1890, against 1,642 vessels, with a capacity of 3,964,112 cubic metres, in 1889.

The Zone System in Holland.—The State Railways Company will introduce the zone system in Holland, by way of experiment, when the summer train service comes into force on the 1st of May next.

Telegraphs.—The State Telegraphs Administration in Holland has practically decided upon adopting the English system of opening accounts current with the press, well-known firms, and other customers, thus obviating payments at the time of telegraphing and frequent delays.

STOCKHOLM, 31st January, 1891.

Railway Construction in the Past Year.—During 1890 the building of railways has proceeded rapidly in many parts of Sweden. Of the important Mora-Venern Railway a distance of 50 kilometres was opened for traffic between Aforsen and Vansbro. Of the Falun-Rattvik-Mora line, a length of 24 kilometres was opened between Slättberg and Rattvik. The Stockholm-Rimbo-Rjursholm line has been opened for traffic, with a length of 35 kilometres. On the Norrland Main State Railway about 90 kilometres, between Aunsidsjö and Nyoker, have been levelled and partly railed, and the works have been extended some 9 kilometres to the north of Nyoker, as far as Högbränna. The large bridges over the Ore and Usne rivers have been commenced, and several smaller works in connection with the diversion of rivers have been advanced. It is expected that the traffic will be opened as far as Värmös during the present year. While the works on the North Main State line are being pushed on with energy, those on the Lulea-Gellivara-Ofoten line of the Swedish-Norwegian Railway Company have been entirely discontinued. The State is continuing its negotiations with the company for the purchase of the railway, and a decision will probably soon be arrived at. The Skymnös-Munkfors Railway, which is a continuation of the Nordmark-Klacelfoen Railway, has been opened for traffic (length, 24 kilometres), and a railway of 23 kilometres has been opened between Vettsjö and Hessleholm.

Concessions for New Railways.—During last year concessions were granted for new lines of an aggregate length of 333 kilometres, with a calculated cost of 11,028,200kr. Applications for concessions are still pending for further railways, with an aggregate length of nearly 300 kilometres, at an estimated cost of 21,134,400kr.

The Agricultural Society's Meeting at Gothenburg.—The preparations for the Royal Swedish Agricultural Society's meeting, which is held at intervals of five years, are being proceeded with in various directions, and the meeting is likely to be an interesting one. The principal Swedish makers will be fully represented, and foreign makers will have large exhibits. The exhibition of scientific dairy appliances will probably be specially attractive.

Digitized by Google

THE ADELFORS GOLD MINE.—This old mine, which has not been worked for about a hundred and fifty years, passed some time ago into the possession of a German syndicate. It would seem that this property is likely to turn out a very valuable one. The modern improvements for extracting the gold from comparatively poor ores increase the prospects of the undertaking.

WORKMEN'S SHARE IN PROFITS.—The proprietors of the Ruben tobacco manufactory in Carlscrana have informed their employés that they are to share in the net profits of the works in accordance with a fixed scale. This arrangement benefits the travellers, the clerks, and the workmen.

CHRISTIANIA, 31st JANUARY, 1891.

SILVER MINING.—The old Kongsberg Silver Works have during their last working year produced about 5,523 kilogrammes of pure silver, which is not a satisfactory output. The prospects are not bright, for, although the rise in the price of silver has helped to improve the result, prices are much lower than they were ten years ago; moreover, some of the old mines show signs of exhaustion. This more especially applies to the "Kongens Grube," which is looked upon as the main mine. The above quantity of silver was sold for a sum of 631,339kr., averaging 117kr. 28 öre per kilo. The aggregate receipts of the works amounted to the sum of 819,073kr., with an expenditure of 700,874kr., leaving net profits of 118,199kr. The smallness of the net profits must be attributed to heavy and extraordinary expenses. The best yield during the last year has been from the Armen mine and the "Gottes Hülfe in der Noth" mine. A couple of English companies are working, in an experimental way, the Kinoren (Christiania) and the Triangel mines. Some rather promising findings are understood to have been made, but the work has been suspended for the present pending the formation of a larger company. The Jacob Kuntsen Mining Company are short of capital, and are endeavouring to make arrangements with an English syndicate, but so far without success. In other places experimental workings have been made with a view of obtaining some negotiable property.

GOLD MINING.—The gold findings at the Bömmelö have been worked by three companies, the Oscar Gold Company, the Hongsmid Gold Syndicate, and the "Bömmelö Bergverkaselskab." The Hongsmid concern has during the year met with some promising findings, and although the quartz, when accompanied with visible gold, appears to be poor, the prospects for this syndicate are looked upon as fairly hopeful. The Oscar Company works with much perseverance, and the results so far obtained, although not yet remunerative, warrant expectations of better times.

MADRID, 2ND FEBRUARY, 1891.

CURE FOR VINE DISEASE.—Senor Don Rosendo Bonfill, an engineer of Barcelona, states that he has discovered an effective and cheap cure for phylloxera, the cost not exceeding £4 per acre. He applies the ingredient to each vine plant, and prevents the attack of the disease, or cures the plant if it has been already attacked. He has been making some experiments on vineyards, where the disease had already done much damage, in order to try the efficacy of his remedy.

NEW MUNICIPAL PALACE.—The Madrid Municipal Corporation have officially announced their intention of building a new set of offices. The site which has been chosen is a garden called "El Buen Retiro," which adjoins the fine park, El Retiro. The building will stand at one corner of an entrance to the Prado, the other corners being occupied by the War Office, the Bank of Spain, and the palace of the Marquis of Linares. As these are large and fine buildings the new buildings of the Corporation ought to be of an equally fine architectural character. A Bill will probably be presented at an early sitting of the Cortes, in order that the Corporation may be enabled to take possession of the land.

MINING EXHIBITION AT BILBAO.—It is proposed to hold a Mining Exhibition on a large scale at Bilbao in 1892. The building which is to be erected for the purpose will be of a permanent character, and will be afterwards used as a museum and technical laboratory for the training of workmen in mining and metallurgy. The management of the Exhibition will be in the hands of the provincial authorities. The future of the metallurgical and engineering industries in Bilbao seems very promising, and the proposed Exhibition is likely to aid their progress.

MERCURY MINES.—The Almaden mine, during 1890, produced 50,035 flasks, against 49,477 flasks in 1889. The yield of the ore last year was nearly as much as in 1889, being just under 9·30 per cent. Other mines in Asturias, belonging to the "El Porvenir" Company, produced 1,450 flasks. The yield of this ore, though only about 1 per cent. on an average, gives a profit.

ROME, 2ND FEBRUARY, 1891.

GROWTH OF MECHANICAL INDUSTRIES.—The largest and almost the only buyers of the machinery made in Italy, excluding the shipbuilding trade, are the Italian railway companies, and, in fact, the history of the mechanical industries of this country coincides with the development of the railways. When, in 1839, the first eight kilometres of railway were made, there were no works in Italy that could supply rails, engines, and waggons, or build iron bridges. The first works erected in Italy were the Officine di Pietrarsa e Granili, which were maintained on behalf of the Government mostly for repairs, and it was only after the year 1879 that a large number of private works were started. Thus, in 1879, Messrs. Gio Ansaldo & Co., of Sampierdarena, were the only firm that manufactured locomotives in Italy, whilst now there are Messrs. E. Breda, the Maschinenfabrik of Saronna, Messrs. Miani Silvestri & Co., the Officine di Pietrarsa e Granili, and other smaller works. In 1879 there were very few firms manufacturing cars and waggons, whilst now there are the extensive works of the Impresa Industriale Italiana, Fratelli Diatto, the Officine di Savigliano, Fratelli Invitti, Società Veneta Officine di St. Elena, Messrs. Miani Silvestri & Co., Felice Grondona, and the Officine di Pietrarsa e Granili. Then, again, twenty years ago there were only two or three firms building iron bridges, whilst now there are from fifty to sixty, including both large and small works.

CRISIS IN THE ENGINEERING TRADE.—The engineering trade of Italy is at present suffering severely from the evil effects of excessive competition and over-production. Various remedies have been suggested by competent authorities in order to effect a remedy for this state of affairs, and restore the engineering trade to a satisfactory condition.

CAUSES OF THE CRISIS.—With the plants now existing for the manufacture of locomotives and waggons and the like, the estimated total production of such works would amount to £1,510,000 per annum. On the other hand, the requirements of the Italian railway companies only amount to from £1,000,000 to £1,200,000. The manufacturers of iron bridges and similar works, with the present low prices due to the excessive competition, ought to have a production of from 80,000 tons to 100,000 tons per annum in order to make an average fair profit, whilst the requirements do not exceed 40,000 tons per annum. The production being thus largely in excess of the requirements has caused the present crisis. The reason for this excessive development is to be found in the fact that some of the works assumed larger contracts than they were able to turn out. They were therefore obliged to enlarge their plants in order to carry out these contracts, and afterwards found themselves with a plant too large for the normal requirements.

REMEDIES FOR THE PRESENT CRISIS.—The question as to the remedies to be adopted is now being discussed in the Italian Parliament. It has been proposed that the Government and the railway companies should now place their orders for all their requirements during a period of the next ten years, which the manufacturers should execute during that period at a reasonable price. Others propose to extend the market, which is actually too small for the production of our industries, and that manufacturers should receive from the Government a premium on exportation, as is done in Germany. A further proposal has been made that all the work of our Government and railway companies should be distributed among the manufacturers proportionately to their respective capacity, thus guaranteeing to all the works a minimum of orders for a certain length of time to come. This latter plan is the one which will most probably be adopted, and, in fact, the Minister of Public Works has now named a commission of experts to carefully study the matter and report as to the real capacity of each of the Italian mechanical works.

NEW YORK, 24TH JANUARY, 1891.

SUGAR MAKING PLANT.—The Fort Scott Foundry and Machine Works Company, of Fort Scott, Kan., has received a large order for sugar making machinery from Edinburgh, Scotland. The order is for a large sugar manufacturing concern in Honolulu, Sandwich Islands. The machinery ordered consists of a patent improved quadruple evaporator, with a capacity to evaporate 1,500,000lb. of water each twenty-four hours, which is equal to the production of 200,000lb. of sugar in the same time.

RAPID TRANSIT IN NEW YORK.—Articles of incorporation of a company organised to construct a tunnel from New York to Brooklyn were filed in Albany on the 19th inst. The incorporators include some of the strongest money interests in the country. The organisation of this company is the first step to furnish the city with what is believed to be the only adequate system of rapid transportation. Not only are New York and Brooklyn to be connected, but each is to be connected with Jersey City, and New York City is to be tunnelled on both the east and west sides from the Battery to Jerome Park. The entire scheme involves the boring of forty-two miles of tunnels, large enough to accommodate a double track of railway, and will involve the expenditure of $61,000,000. Much preliminary work has been done, and borings have been made at every 500ft. of the proposed tunnel. With the exception of a distance of 2,400 feet in the North River, and a short distance in the city, the entire excavation will be through solid rock. The Brooklyn tunnel, on which it is proposed to begin work, will be 6,050ft. long, and 5,000ft. between stations. The underground station, as proposed, will be 330ft. long, 60ft. wide, and 30ft. high. Elevators having a capacity of 340 passengers per minute will be used to bring passengers to the surface. The incorporators estimate the cost of the tunnel itself at $1,250,000 a mile, exclusive of working plant.

COLORADO COAL MINES.—The Colorado coal mines, according to the *Engineering News*, produced 5,476,410 tons in the two years 1889-90. The coal production of 1873 was less than 70,000 tons; in 1890 it was 3,075,782 tons. Of this quantity the Las Animas mine produced last year 1,134,845 tons. The value of the coal taken out in 1889 and 1890 at the mines was $10,408,930, and nearly 6,000 men are employed. The average value of the coal in the cars at the mines is $1·87 per ton, for 1890.

THE PINTSCH SYSTEM OF CAR LIGHTING.—The Chicago and North-Western Railway has decided to replace the kerosene oil lamps in its passenger cars with the Pintsch system, and is erecting its own gas works. One great obstacle in the adoption of this system of lighting, says the *Railroad Gazette*, has always been the difficulty of recharging cars which have to make long round trips. The number of gas works for furnishing Pintsch gas has within the last year largely increased. Works have recently been erected in New York City, Jersey City, Syracuse, Boston, Cincinnati, St. Louis, Denver, Ogden, and Atlanta.

LOCOMOTIVE CONSTRUCTION.—Twenty-seven locomotives are in course of construction at the Baldwin Locomotive Works, which, when built, will be shipped to New South Wales, Australia. This is the largest foreign order filled by the Baldwin Works.

PHILADELPHIA, 23RD JANUARY, 1891.

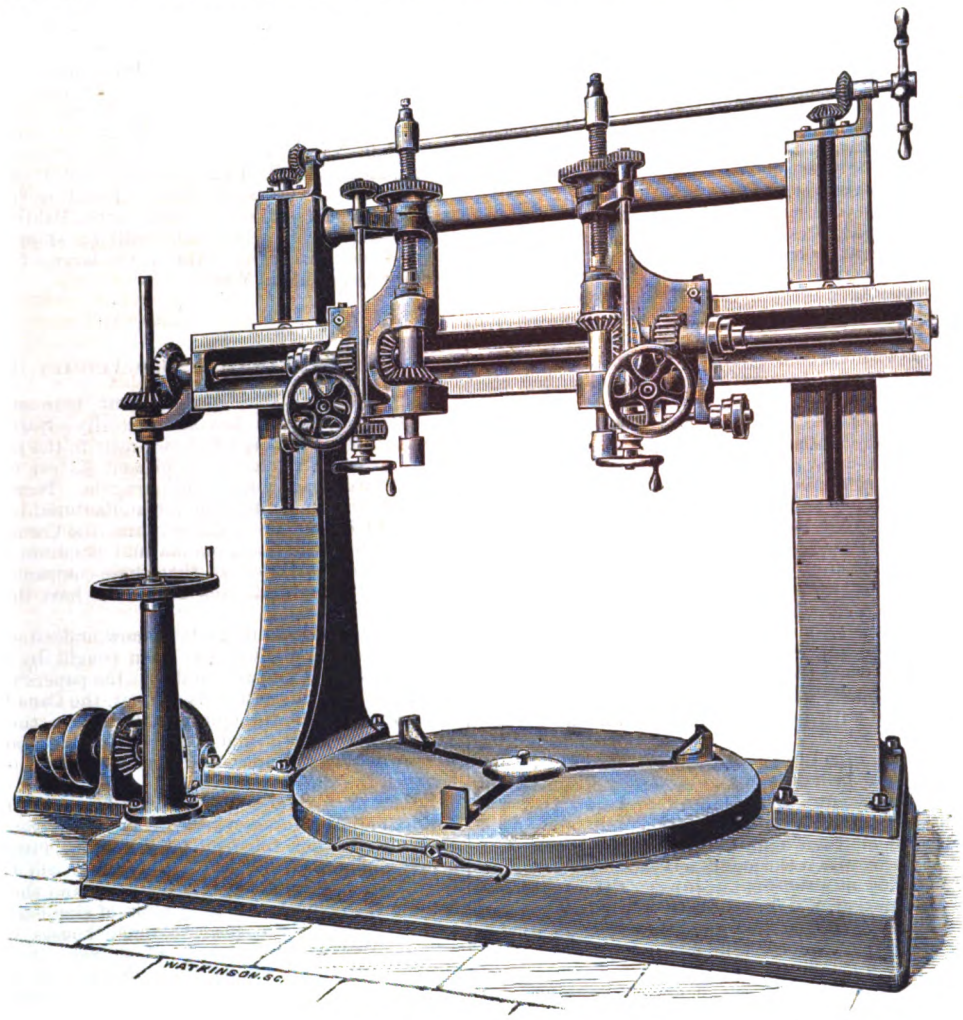
STEEL RAILS.—The disagreement between steel rail producers has been at last satisfactorily adjusted, and the manufacture of rails is now practically in the hands of six companies. The price is at present $3 per ton over the lowest prices made during the struggle. There were until lately eleven companies which manufactured rails, but the Illinois Steel Company absorbed three, the Carnegie bought out one, and the Lackawanna and Scranton Companies have been consolidated, so that these companies, with the Cambria, Pennsylvania, and Bethlehem, have the control of the market.

RAILWAY EXTENSION.—It is now understood that the Niagara Central Railway has been bought by the Lehigh Valley Railway Company, and that the papers were signed last week. If this report is correct, the Canadian Pacific will probably run through Hamilton from the Bridge to Toronto very shortly, and when the Toronto, Hamilton, and Buffalo Railway is constructed, competition will be set up between the various companies.

RAILWAY STORAGE YARD.—The large transfer, classification, and car storage yards of the Pennsylvania Railroad at Walls Station, fourteen miles east of Pittsburgh, are nearly completed. In these yards there will be facilities for taking care of 5,000 to 6,000 cars, and the yards will contain the equivalent of sixty miles of single track. These, with two transfer stations, two round houses, and two car repair shops, will cost nearly $1,000,000. It is intended that in these yards all freight trains will be so made up that cars can be dropped at their destination without further arrangement. All traffic not destined for Pittsburgh will hereafter be carried around that city.

THE EDISON COMPANY.—The report of the year's business of the Edison General Electric Company states that the company has now in operation 1,371,000 lamps, and that more than three-quarters of a million dollars were expended on the plant at Schenectedy, New York, which will manufacture underground cables under the Siemens and Halske patents. During the year the production of the Schenectedy works increased by 117 per cent., and the sale of lamps increased 64 per cent. The gross profits for the year, after charging $206,000 for depreciation of plant and an equal amount for general expenses, were $1,896,177. The profits from the Edison Electric Light Company, which is owned by the General Company, were $1,023,011, which sum is not included in the above. The assets of the General Company are estimated to exceed its liabilities by $5,250,000. In this city the large Edison station is slowly approaching completion. At present the plant supplies 56,000 lamps of 16 c.p., and 7,000 lamps additional are being put in. The gross receipts were $190,000, and expenditure $120,000, and the net earnings, deducting interest accounts, amounted to $63,000.

PLATE GLASS FACTORY.—There is now in course of erection at Irwin, Pa., one of the largest plate glass plants in America. The firm will be known as the Pennsylvania Plate Glass Company. The contract for the building and its equipments has been placed with the New York firm of Messrs. A. C. Boyd & Co., which erected the large Tarentum and Howard plants in Allegheny Co. Over 600 men will be employed in the establishment, which will cost about $1,000,000.



THE "NEWARK."—The report of the engineer officers detailed to watch the performance of the engines of the cruiser "Newark" on her recent trial trip was submitted to the Secretary of the Navy on the 22nd inst. It shows an indicated horse-power of about 9,000, or an excess of 500 horse-power over the contract requirements, and entitles the contractors to a premium of nearly $50,000.

STEEL WHALEBACK VESSELS.—The Steel Barge Company, of Duluth, has determined to establish a shipyard on Puget Sound for the building of its peculiar style of vessels for the Pacific coast trade. The cost of the yard will be about $1,000,000, and it will be larger than the original yard in Duluth. The company has submitted plans for its vessels to the United States Government, and may establish a shipyard on the Atlantic coast

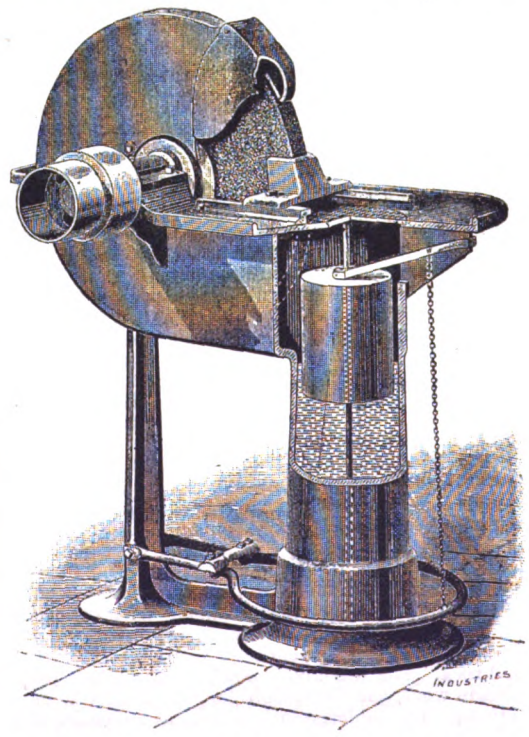
BOILER FLUE FLANGE DRILLING MACHINE.

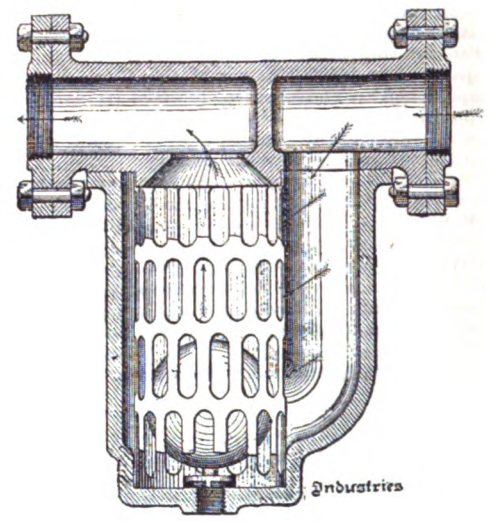
CONSTRUCTED BY MESSRS. GEO. BOOTH & CO., CENTRAL IRON WORKS, HALIFAX.



BOILER FLUE FLANGE DRILLING MACHINE.

The above illustration shows a special drilling machine adapted for drilling the holes in boiler flue flanges from 1ft. 10in. to 4ft. 6in. diameter and 1ft. 10in. to 4ft. 6in. in length. The machine has been constructed by Messrs. Geo. Booth & Co., Central Iron Works, Halifax, for Messrs. Penman & Co., boilermakers, Glasgow. The spindles are steel, 2¼in. diameter, and carried in long cast-iron sockets, the bottom end of which is conical and the top end fitted with nuts and washers for adjustment. Each spindle is fitted with a self-acting feed motion of 8in. traverse, and with a convenient arrangement for quickly engaging and disengaging the feed motion. The saddles can be easily adjusted to any position on the cross slide by a rack and hand-wheel placed conveniently in front of the saddles. The flues, while being drilled, are fixed on a circular table, which is fitted with three universal chuck jaws. The table is rotated by the hand-wheel shown in front of the left-hand standard. The machine is driven by a three-speed cone pulley, and is very conveniently arranged and substantially built. It is capable of executing work expeditiously, and is, we understand, giving Messrs. Penman every satisfaction.

THE BARNES WATER EMERY GRINDER.



WE are indebted to our American contemporary, the *Electrical Engineer*, for the accompanying engraving, which represents an improved method of mounting an emery wheel. To the front of the curved treadle, pivoted to the rear standard and bent to encircle the water column, is attached a lever, whose free end carries a float. By pressing with the foot upon the treadle, the float may be made to enter the water chamber, thereby displacing the water and forcing it to rise and supply the wheel. When the machine is not in use the float rises and the water flows back out of the way of the wheel. This arrangement does away with all pumps and valves, which are liable to get out of order, simplifies the machine, and makes it more practical

under all conditions. The float chamber is divided from the chamber in which the wheel revolves by a partition, having in its lower part a small hole, through which the water slowly enters the wheel chamber. The action of the wheel carries the water to its front upper quarter, where it is arrested and thrown into a pocket, from whence it falls to the wheel and tool. The pocket is shown in the engraving with the outer shell broken away. Without the partition referred to, the water would be flooded into the wheel in a large volume, which would be undesirable. The small hole being in the bottom edge of the partition, allows all the water to flow back into the reservoir when the float rises. This construction simplifies the machine and renders it more efficient, and allows it to be used in shops where there is no water piping. The grinder is constructed by the W. F. & John Barnes Company, of Rockford, Illinois, U.S.A.

A NEW WATER SEPARATOR FOR STEAM PIPES.

THE accompanying illustration represents, in section, another addition to the many devices designed to avert the breakdown of steam engines from "priming." The separator we now illustrate has been invented by Mr. H. C. White, and is made by the Barnard Engineering Company, of 15, Cortland Street, New York, U.S.A. The action of the apparatus is fairly simple. Steam on its way to the engine is diverted in the direction shown by the arrows, and is prevented from passing directly through the T-shaped casting by a transverse wall, which deflects the flow of steam and suspended water

through the central cage, where the water is deposited by gravity and is drained off by a drip-pipe in any convenient manner. A glass gauge placed on the lower casting shows at a glance the height of the water in the separator. In case of an unusually large flow of water, greater than can be carried away by the drip-pipe, the ball will float on the surface, and, should the water rise sufficiently high, will become seated against the conical seating shown, and thus prevent the water escaping into the steam cylinder. We have some doubt about the ball leaving its seat, however, after the water below it has drained away. We are indebted to our American contemporary, the *Engineering and Mining Journal*, for our illustration.

SOCIETY OF ENGINEERS.

THE first ordinary meeting of the Society of Engineers for the present year was held on the 2nd inst. Mr. Henry Adams, the President for the past year, first occupied the chair, and presented the premiums of books awarded for papers read during his year of office, viz.:— The "President's Premium" to Mr. W. H. Brothers, for his paper on "Weighing Machinery and Automatic Apparatus in Connection Therewith"; the "Bessemer Premium" to Mr. R. H. Tweddell, for his paper on "Application of Water Pressure to Machine Tools and Appliances"; a "Society's Premium" to Mr. P. Griffith, for his paper on "Treatment and Utilisation of Exhaust Steam," and to Mr. W. Santo Crimp, for his paper on "Sewer Ventilation." Mr. Adams then introduced the President for the present year, Mr. William Newby Colam, to the meeting, and retired from the chair.

The new President then took the chair, and proceeded to deliver his inaugural address. After thanking the members for having elected him as President, he alluded to the very satisfactory position of the Society, the muster roll now showing a total of 448 members of all

Digitized by Google

classes, and reviewed its work during the past year, which consisted in the reading and discussion of papers during the session, and of visits to works of professional interest during the vacation. He gave a brief outline of the papers read, and touched on the works inspected, which include the Thames Ironworks, Blackwall, the Royal Arsenal, Woolwich, and the London and North-Western Railway Works at Crewe. The President then indicated the advances which have recently been made in the practical application of electricity, both as a motive power and as an illuminant, and said that these advances were but small. He referred to the opening of the City and South London Electric Railway, and described some projected lines which it was proposed to work on the same principle, observing that the working and financial result of the system on the South London line was being closely watched in connection with the further proposed applications. He then described the special points of an electric tramway system proposed by Mr. Mansfield of New York, and which is on the "Spot" principle. Referring to primary batteries, the President observed that it was some time since they were previously heard of, but that three had made their appearances, during the past year. In electric lighting he said there had been no striking advances made as regards public street lighting. The St. Pancras Vestry had, however, set the first example of self-supply, and had started the building of an installation for supplying the parish without the intervention of outside companies. The applications of electricity to welding and to other industrial purposes were then referred to and briefly described. These applications include the manufacture of chlorate of potash, soda, paper pulp, chloride of lime, caustic soda, and leather.

The President said that he had only this week returned from an exhaustive professional tour through America, where he had been much impressed with the efforts that were being made to meet the modern demands for rapid transit in streets. He referred to many wonderful mechanical contrivances, some of which had been tried and condemned; others were being experimented with or were about to be tested as street motors. He thought that the cable system had given by far the best results mechanically and financially. In matters relating to mining and metallurgy, the President referred to the discovery of a perfect lode of uranium in Cornwall, to that of gold-bearing ores in France, and to that of coal in Kent. Elmore's process of producing copper tubes and cylinders direct by electro-deposition was described, and particulars of the tests of the metal produced were given. The Graydon dynamite gun, the manufacture of which has only just been completed, was also described, and the President concluded a most interesting address by referring to the opening of the Forth Bridge, the satisfactory progress of the Manchester Ship Canal, the progress of the Nicaragua Canal, and the efforts now being made to resuscitate the Panama Canal.

SHIPBUILDING NOTES.

On the 23rd ult. the s.s. "Ashley," built by Messrs. Craig, Taylor, & Co., of Stockton-on-Tees, to the order of Mr. Wm. R. Rea, of Belfast, for the North of Ireland Steamship Company, Limited, was taken out for trial. Her engines, supplied by Messrs. Westgarth, English, & Co., of Middlesbrough, have cylinders 21in., 34in., and 56in., with 39in. stroke, with two large steel boilers working at 180lb. pressure, and worked very satisfactorily, a speed of nearly twelve knots being obtained.

On the 24th ult. Messrs. Edward Withy & Co. launched from their yard at Hartlepool a large steel screw steamer, built to the order of Mr. F. Woods, London. Her length is over 320ft., and she is built throughout of Siemens-Martin steel, with a large measurement and dead-weight capacity, and is of the highest class at Lloyd's. The vessel has a long raised quarter-deck, short poop, long bridge-house, and a topgallant forecastle. The holds are fitted with iron grain divisions and iron cargo battens, all decks, deck erections, skylights, bulwarks, and bulkheads being constructed of steel and iron. A cellular bottom is fitted all fore and aft for water ballast. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. Four steam winches, two donkey boilers, patent steam steering gear amidships, screw gear aft, direct steam patent windlass, stockless anchors hauling up into the hawse pipes, and other modern appliances are fitted for the handy working of the vessel. She will be fitted with triple-expansion engines by Messrs. T. Richardson & Sons, Hartlepool.

On the 27th ult. an iron screw steamer of 3,250 tons gross was launched from the shipbuilding yard of Messrs. D. & W. Henderson & Co., Meadowside. The vessel is intended for trade between Calcutta and China, and has been built to the order of Messrs. Apcar & Co., Calcutta. The dimensions of the vessel are as follows:—Length, 452ft.; breadth, 42ft. 9in.; depth, 28ft. 9in. The triple-expansion engines have cylinders 27½in., 44in., and 72½in. in diameter.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, February 6th, at 9 p.m. Lecture on "Some Applications of Photography," by the Right Hon. Lord Rayleigh, F.R.S.

SANITARY INSTITUTE.—Friday, February 6th, at 8 p.m. Lecture on "Water Supply, Drinking Water, Pollution of Water," by Dr. Louis Parkes.

GEOLOGISTS' ASSOCIATION.—Friday, February 6th, at 7.30 p.m. Presidential Address on "Further Notes on the Geological Record," by Mr. T. V. Holmes.

SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS MANAGERS.—Saturday, February 7th, at 6.30 p.m. Paper to be read: "The Theoretic Rationale of an Improved Design of an Open-hearth Furnace," by Mr. B. H. Thwaite.

NEXT WEEK.

SANITARY INSTITUTE.—Monday, February 9th, at 8 p.m. Lecture on "Drainage," by Professor H. Robinson, M.Inst.C.E. Wednesday, February 11th, at 8 p.m. Paper to be read: "Model Dwellings in London, and Overcrowding on Space," by Dr. Louis Parkes.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, February 10th, at 8 p.m. Discussion on the paper of Messrs. Atkinson on "Electric Mining Machinery."

SOCIETY OF ARCHITECTS.—Tuesday, February 10th, at 7.30 p.m. Ordinary meeting.

ROYAL VICTORIA HALL.—Tuesday, February 10th. Lecture on "Plants and Animals of the Coal," by Professor H. G. Seeley, F.R.S.

SOCIETY OF ARTS.—Wednesday, February 11th, at 8 p.m. Lecture on "The Proposed Irish Channel Tunnel," by Sir Roper Lethbridge, M.P.

OWENS COLLEGE UNION ENGINEERING SOCIETY.—Wednesday, February 11th, at 7 p.m. Union social meeting.

INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, February 12th, at 8 p.m. Discussion on "The Distribution of Electricity, with Especial Reference to the Chelsea System," by Major-General C. E. Webber, C.B., R.E.

PRICES CURRENT, 4TH FEBRUARY, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

,, English Ingots	93	10	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER continues very quiet, with limited business. Transactions in raw copper during the past week have been unimportant, and values have gradually declined, to-day's quotations for Chili bars being £52 to £52 5s. cash, with small business reported. Manufactured quiet, with small demand; "strong," £66.

TIN is a shade firmer to-day, but prices of foreign are about 15s. per ton lower on the week.

LEAD: Inactive, with values a shade lower.

SPELTER is easier, a good deal of spelter having come forward on the breaking up of the ice at German ports.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: There is a good demand for general chemicals, and values, with few exceptions, are well maintained. In caustic soda, soda ash, and bleaching powder there is no change. Sulphate of ammonia is improving, and makers are quite disinclined to sell forward. Green copperas is rather quieter, but prices remain firm. Sulphate of copper in second hands is pressed for sale at considerably under present cost of manufacture. Acetates of lead and nitrate of lead are moving off better. Acetate of soda continues scarce.

HOME INDUSTRIES.

LONDON, 5th February, 1891.

The Money Market.—Rates in the money market have hardened considerably, the revenue collections having diminished the floating supply of money by transferring it to the Government account at the Bank of England. Discount rates have been affected by the revival of the drain of gold to Berlin, which has proceeded intermittently. In the stock markets business remains dull and featureless. The better class of investment securities continue in fair request, but the investment buying of home railway stocks has fallen off, and in the absence of speculative dealing this market has been quiet. Brighton Deferred alone has been active, but the activity has not produced much effect. American railway shares have been somewhat brisker in response to New York, but little disposition to raise prices has manifested itself on this side. Canadian railway stocks have been steady. There has been no movement of consequence in foreign securities, Argentine, Chilian, and Portuguese bonds moving in accordance with the news of the hour. Silver securities have been quiet and depressed. South African mining shares have revived, the arrival of Mr. Rhodes in London drawing fresh attention to them. Industrial and miscellaneous securities have presented no feature.

The Royal Institution.—On the 30th ult. a lecture on "The Rejuvenescence of Crystals" was delivered at the Royal Institution by Professor J. W. Judd, F.R.S. The author said that the study of crystallogenesis in England had been begun by Robert Boyle, and the credit of British discovery had been maintained by the researches of Brewster and Sorby. The study of crystals had been of great assistance to the geologist, and the debt which the geologist owed to the chemist was more than repaid by the geologist's study of naturally formed crystals. Crystals had the powering of resuming their growth after an interruption of millions of years. If a crystal were taken from a solution, and afterwards returned to a similar solution, the growth of the crystal would continue as before. A specimen of the amethyst variety of quartz, surrounded by shells of the colourless variety of quartz, was shown. The formation of crystals depended on the temperature, the rate of deposition of material, the nature of material supplied, and the presence of foreign bodies, often quite minute, which, though themselves unaltered, had the power of completely altering the character of the crystal. The lecturer then described the formation of "zoned crystals," in which zones of different colours had been found during the growth of the crystals. If a crystal were injured, and the injury were not too deep, the crystal would complete itself before it continued its growth. In the mineral world, the smallest fragments of crystals were capable of continuing their growth. Some of the lower forms of animal life and plants had similar powers of attaining a complete existence.

Cheap Trains for London Bill.—A Bill has been introduced into Parliament by Mr. Theobald, which is intended to afford to workmen increased facilities for transit between their houses and their work. The Bill, which is an extension of the Cheap Trains Act of 1883, fixes a maximum return fare of a halfpenny per mile of the distance between the station and the terminus by all workmen's trains, from any station within twelve miles of the terminus, arriving at a London terminus before 8 a.m. The tickets are to be available for the return journey by any train departing from the terminus after 5 p.m. on the day of issue (the hour of 12 noon being substituted on Saturdays). Permissive powers are to be given to the Board of Trade to enforce the regulations of the Bill.

The Royal Naval Exhibition.—On the 31st ult. the First Lord of the Admiralty visited the grounds of the Naval Exhibition in order to see the arrangement of the buildings and the progress that had been made. He was met by Admiral Sir William Dowell, chairman, and Admiral Sir W. H. Stewart, vice-chairman, of the executive committee; Sir George H. Chubb, chairman of the finance committee; Captain A. Jephson, R.N., honorary secretary; and Lieutenant Gerald Maltby, assistant honorary secretary; and, after seeing the plans, was escorted round the whole of the buildings and grounds, where work on an extensive scale is in progress.

London Geological Field Class Lectures.—A course of four lectures, on "The Gravel Beds of the Thames and its Tributaries in Relation to Ancient and Modern Civilisation," will be delivered by Professor H. G. Seeley, F.R.S., on Saturdays, February 7th, 14th, 21st, and 28th, at 4.15 p.m., at the Gresham College, Basinghall Street. Tickets are to be had of Mr. J. H. Hodd, Hon. Sec., 78, Queen's Road, Finsbury Park, N.

Engineering Tenders.—The London County Council invite tenders up to the 10th inst. for work in connection with the construction of a weir at the Barking Outfall Sewage Works. Forms of tender may be seen at the Engineer's Department, Spring Gardens, S.W.—The Wimbledon Local Board require a new steam fire engine, with hose. Tenders are to be sent in by the 10th inst. to Mr. W. H. Whitfield, Clerk, Broadway, Wimbledon.

MANCHESTER, 5th February, 1891.

The Ship Canal.—The annual general meeting of the shareholders of this company was held on the 3rd inst., and there was an unusually large attendance, owing to a somewhat alarming report. It was stated on behalf of the directors that the contract existing with the executors of the late Mr. Walker had been rescinded and the works taken over by the company. Disputes had arisen under the contract between the directors and the executors, and the result was a resolution to free the latter from further control. The bargain concluded involved the acquisition by the company of plant amounting in value to £943,640, which sum had been advanced to the contractor by the directors, and which was to have been paid back in instalments. The effect of this is that much of the capital is locked up. In consequence also of extra works having been forced upon the company or carried out to increase the ultimate capacity of the canal, the borrowing powers of the company have been exhausted. It is therefore proposed to apply to Parliament for powers to obtain additional capital to the amount of £1,700,000 in order to complete the works. It was stated by Lord Egerton that this sum was more than covered by assets which could be realised at a profit after the opening of the canal, but not so profitably before that event. Mr. James Abernethy, C.E., had been asked to go over the works and report, and his report, which was read, was a very favourable one. The work at each extremity of the canal was in a very forward condition, and the remainder quite up to time. The plant at work was:—Horses, 187; waggons, 300; steam navvies, 96; steam cranes, 144; portable and other engines, 184; steam pumps, 212; miles of temporary railway, 228; and the number of men and boys employed, 15,000. The original estimate of land required was 2,845 acres, at a cost of £689,986, but 4,258 acres had been actually bought, at a cost of £1,022,390, of which 2,300 acres could be resold. As a further offset the dock space had been increased by 14 acres, the quay space by 69 acres, and the quay frontage by 1½ miles.

The Linen and Jute Trades.—The home demand has for some time been slow, and transactions are scarcely up to the average for the time of the year. The dulness of the foreign demand makes this want of activity all the more keenly felt, and, as the season is evidently to be a "backward" one, buyers being unwilling to operate for the future, there will be some difficulty in keeping up returns for the first quarter of the year. The partial resumption of traffic on the Scotch railways has enabled merchants to secure more prompt deliveries of Fifeshire linens here.

Indian Mills.—Some interesting statistics have been published with reference to the growth of the Indian cotton mills. In 1887 there were 103 mills, containing 2,421,920 spindles, the numbers being now 137 mills, with 3,274,196 spindles. The number of looms in the same period had increased from 18,356 to 23,412, and the number of workpeople now employed is 102,000. There is a keen interest being shown in the proposed Bill to deal with the hours of labour in Indian factories, and it need hardly be stated that the feeling in this district is almost universally in favour of it.

Quadruple Expansion Engines.—There is considerable activity prevailing among engineers, and several new departures are spoken of. The quadruple-expansion engines to which allusion was made recently are for a new mill in Bury, and are to be constructed upon the principles patented by Mr. Ferguson, of Paisley. Messrs. Musgrave & Sons, Limited, are to be the makers of this type of engine, as they have acquired the patent rights for England. The boilers which are to be employed are of the Lancashire type, each 30ft. by 7ft., and are to be constructed by Messrs. Edward Heaton & Son, of Manchester. The steam pressure to be used is 200lb. to the square inch, and this will be the first time that boilers of this type of such a size have been constructed for this pressure. We have given particulars of two smaller-sized boilers of this type for similar pressures which are the pioneers in this direction. The movement towards engines with greater expansion is gradually making progress in this district, an Oldham limited company being about to adopt triple-expansion to replace their present engines. As a rule, millowners still prefer the ordinary compound type, but as the limit of economy has been reached in this direction there is every likehood of a new departure being generally made.

Removal of Unhealthy Houses.—Acting upon a recommendation of the Sanitary Committee the Manchester City Council have determined to promote a scheme to demolish a large number of insanitary houses, and either make open spaces or cover the same with improved dwellings. In one of the districts of Manchester workmen's houses are being erected which retain the principle of self-contained dwellings, while at the same time they are fitted up in a superior manner and contain a number of improvements. This is an attempt to provide accommodation for the working classes free from the objections inherent in the tenement system.

Second-class Fares.—The chairman of the Manchester, Sheffield, and Lincolnshire Railway Company at the annual meeting, held recently, announced that in view of the very serious decrease in the number of passengers carried in second-class compartments they proposed to abandon their use except in certain suburban trains. The shareholders approved of this course, and it is announced that the change will take place on the 1st April next.

Manchester Gas Works.—Some interesting statistics have been published relative to these works. The mains extend a distance of ten miles, and 677 miles of mains are laid; 11,842 lamps exist within the city, 2,241 beyond it. The total producing power of the works is 16,368,000 cubic feet per day, and there is a storage capacity of 15,297,000 in addition. There are 78,259 meters on hire. The gas question is one which is exciting great interest in Manchester at present.

Micrometer Gauges.—Messrs. James Spencer & Co., of Hollinwood, have commenced the manufacture of micrometer gauges, which have hitherto been an American specialty, although largely used in this country. The gauges are well finished, and are made throughout by special machinery. Messrs. Spencer have constructed a gauge on this principle to measure from zero up to 2in., which has not hitherto been accomplished.

GLASGOW, 5th February, 1891.

The Railway Strike.—On the 29th ult. the men on strike belonging to the North British Railway effected a settlement with the company, and on the 31st ult. a similar settlement was arrived at on the Caledonian system. The strike is over, and traders feel a sense of relief, though some of the effects of the struggle may be permanently felt. The amount of loss to the trading public is incalculable. One extensive shipper, who customarily ships from sixty to seventy thousand tons per month, succeeded in shipping, during the six weeks of the strike, only ten or twelve thousand tons. The following is a fair estimate of the loss sustained through the strike. The men on strike have lost, in unpaid wages, £40,000. The loss to the companies in decrease in traffic receipts, in loss of the increment on these which would otherwise have been yielded, and in expenses connected with the strike, increased wages, bonuses, repairs to plant damaged by unskilled hands, may be stated at £200,000. The loss to the public in unpaid wages due to the closing of steel works, shipbuilding yards, factories, and loss of profit during five weeks may be estimated at £500,000. The total loss may thus be stated as £740,000. The close of the strike has caused business to become brisker. So many vessels, which have been laid up during the past six weeks, have offered for employment that freights have not materially advanced.

Shipowners' Club for Small Damage.—A number of Glasgow shipowners have formed themselves into a club for the insurance of small damage. Hitherto 3 per cent. was the limit below which damage was not paid. The extent of capital now invested in very large ships has resulted in this minimum becoming a serious amount; indeed, 3 per cent. upon a large steamer became a sum too large to be disregarded. The club which has been formed will take risk of damage under 3 per cent. to a minimum of ¼ per cent. The manager of the club is Mr. Nelson Bird, accountant, of this city.

Minerals.—The decrease in coal shipments for this year amounts to 158,887 tons. The principal part of this decrease must be set down to the railway strike. An important subject has been raised at the Clyde Trust in connection with the dues for bunker coal. A committee appointed to deal with the subject recommended that dues be henceforward charged for bunker coal. It appeared, however, that, having referred the question of powers to the opinion of counsel, they had found that, though counsel had advised that the Clyde Trust had the necessary powers, some difficulty had been found in enforcing them.

Engineering Bills.—Among Scotch Bills before Parliament this session involving engineering construction, there are the Aire and Calder and River Dun Navigations Junction Canal, the Caledonian Railway (Edinburgh and Leith lines), the Glasgow and South-Western Railway (steam vessels), the Partick, Hillhead, and Maryhill Gas, the Alloa Water, Dundee Water, and the Glasgow Police (Sewage).

Shipbuilding.—Messrs. Caird & Co., Greenock, have contracted with the Peninsular and Oriental Company to build for them two large steamers, each of 7,000 tons.—Messrs. William Hamilton & Co., Port Glasgow, are about to build a sailing vessel of 1,600 tons for a firm in London.—The Greenock yards generally are full of work, the orders which they have received during the past few months being sufficient to keep them busy for a long while.—It is expected that ere long the want of a large crane for shipping heavy machinery at Garvel Dock, Greenock, which has been much felt for a long time, will shortly be remedied by the erection either of large sheer legs or of a crane of suitable size.

High Speed Atlantic Steamer.—The Fairfield Company have now practically received the order to build a vessel to their five-day boat design brought out some years ago.

(From our own Correspondents.)

LIVERPOOL, 4th February, 1891.

The Liverpool and Belfast Steamship Trade.—Considerable interest has been aroused this week at the landing stage by the arrival of the steamship "Manchester" from Belfast, after her first trip. She is intended to compete with the existing company owning the "Dynamic" for the trade between this port and Belfast. She was built in Belfast by Messrs. McIlwaine & McColl, of 2,505 tons net register, has triple-expansion engines indicating 750 h.p., with a cargo capacity of 700 tons. The passage was made in 12½ hours, the speed on the trial trip being 11·78 knots per hour. The steamer is advertised to sail twice a week.

The Timber Trade.—The trade during the past year has been on a large scale, and, although the year com-

Digitized by Google

menced with high prices, they were much reduced by the fall in freights. The high price caused increased the production, and the low freights caused heavy shipments to be forced upon the market. The stocks now held are in excess, and early arrivals will come to a weak market and will prevent any improvement in prices. The mahogany trade has been prosperous throughout the year, light stock and firm prices having been the normal condition.

THE GRAIN TRADE.—Although there have been great fluctuations in the trade to this port during the past fifty years, the imports have increased from 366,000 qrs. of wheat and 15,000 qrs. of maize in 1840 to 3,600,000 qrs. of wheat and 2,560,000 qrs. of maize in 1889. The imports of flour have increased very little, most of this going to London. In 1840 the amount imported was 988,000 barrels; in 1889 it only reached 1,135,000 barrels, although in 1882 the amount was 4,500,000 barrels. The average weekly consumption of the local market is 65,000 qrs. of wheat, 33,000 qrs. of maize, and 31,000 sacks of flour.

IMPROVEMENT AT SOUTHPORT.—The Southport Corporation has received permission from the Local Government Board to borrow the sum of £25,000 for foreshore improvement works. The scheme, which will be commenced immediately, embraces the widening of the existing promenade, the construction of a marine lake covering 27¼ acres, the erection of a shelter to hold 2,000 people, a boat house, and a large salt-water tank, the construction of the lower promenade, and other necessary works.

LEEDS, 4TH FEBRUARY, 1891.

LEEDS ASSOCIATION OF ENGINEERS.—At a meeting of this Association, held on the 29th ult., the President, Mr. Alfred Atkinson, being in the chair, Mr. William Johnson, M.Inst.M.E., read a paper on "Bricks and General Clay-working Machinery." The author spoke of the early efforts to introduce machinery in brickmaking, and showed why a machine, apparently perfect in design, failed utterly when placed in the brickfield owing to the constantly varying materials from which the bricks were formed. He described the several processes—viz., the plastic, the semi-plastic, and the dry—showing that one class of machine is suitable for one process, while an entirely different one is necessary for another. He also gave a description of various edge-runner mills, horizontal roller mills with one or more pairs of rolls, pug mills, and different kinds of compressing machines in use.

STEEL PITCH CHAINS.—The business in steel pitch chains is developing. Mr. John Whittingham, of the Victoria Iron Works, Hull, is supplying steel pitch chains for a variety of purposes, and of strength varying from 10 cwt. to 60 tons. A few of the principal uses for these chains are in connection with traction engines, cranes, hoists, elevators, dredgers, and pile drivers.

SHEFFIELD, 4TH FEBRUARY, 1891.

IRON AND STEEL.—The general condition of the iron and steel trades is fairly good. The high price of fuel operates adversely to local firms when their productions are brought into open competition with Belgian and German makers. Pig iron shows a downward tendency. Hematite is being offered here at 62s. per ton, and common forge iron from 40s. to 43s. General merchant iron is in fair demand, especially the better qualities, which continue to keep up their value. Ship and boiler plates are not selling at all well, owing to the productive power being so largely in excess of requirements. The Atlas Works are busily employed in turning out their specialties. The shop devoted to "Purves' flues" is being considerably enlarged and additional machinery added to meet the demand for these flues. The United States are now importing this flue in spite of the tariff. Steel castings and forgings are only in moderate demand. The use of wrought iron for axles in locomotive engines and rolling stock generally is on the increase. Many of these have now to be case-hardened—that is, converted into steel—at the journals for a depth of ¼in., and afterwards hardened. Messrs. Samuel Fox & Co., Limited, have declared a dividend of 10 per cent. per annum as the result of their year's operations in iron and steel.

ORDER FOR LACE MACHINES.—An extensive order for lace machines has been placed by Messrs. John Bromley & Sons, of Philadelphia, Pa., with Mr. John Jardine, of Nottingham. Messrs. John Bromley & Sons have been hitherto concerned in the manufacture of rugs and chenille curtains, and the plant which is to be laid down by Mr. Jardine will enable the firm to produce 5,000 pairs of finished lace curtains per week.

REGISTRATION OF NEWSPAPERS.—After some correspondence between the Post Office authorities and the Sheffield *Weekly Telegraph*, that newspaper has been removed from the register, so that a higher postage will henceforth have to be paid by its proprietors. The Postmaster-General stated that he would be willing to retain the *Weekly Telegraph* on the list of registered newspapers if "as much as one-fourth part were devoted to news or articles on current topics, provided always that the advertisements did not fill more than half the paper." In some respects the arrangements of the American Postal Service seem preferable to our own, newspapers there being weighed in bulk and distributed at a cost of 1c. per pound.

WIRKSWORTH WATERWORKS.—Mr. W. H. Radford, C.E., of Nottingham, has prepared a scheme for obtaining an increased supply of water at Wirksworth. The town is now supplied by gravitation from springs issuing from out of the millstone grit. There is a large surplus during the winter, but the springs run very low, and there is consequently a scarcity for about three months in the summer. It is proposed to construct an open stone-built reservoir to hold three million gallons for the storage of the winter's surplus.

CARDIFF, 4TH FEBRUARY, 1891.

IRON AND STEEL.—Pig iron makers are finding it difficult to make any profit, and at the Rhymney Iron Works the men have received twenty-eight days' notice, in view probably of a reduction in wages. Steel tinplate bars find a ready sale, but rails are hardly inquired for.

COAL AND COKE.—The steam coal trade continues fairly active, but arrivals of tonnage during the past week have not been so numerous. Colliery owners have, therefore, been obliged to accept a trifle less than last week's quotations, in order to secure immediate release for their loaded waggons. The sliding scale audit has resulted in an advance of 2½ per cent. to the men from the 1st inst. This means 55 per cent. above the standard, and it is clear that the men will make every effort to restrict the output, seeing the favourable position in which they are placed. The consumption must, however, be falling off, on account of the number of boats laid up—which now amount to 250—and it will, no doubt, be difficult to maintain prices at their present level, especially as the ironmakers find it impossible to pay present prices for fuel without incurring a loss. Steam coal is quoted at—No. 1 quality, 15s. 3d. to 15s. 9d.; No. 2, 14s. 3d. to 15s.; No. 3, 13s. 6d. to 14s.; and No. 4, 12s. 9d. to 13s. 3d. f.o.b. Small steam coal realises 7s. to 7s. 3d. Household sorts are moderately firm. Coke is quiet, but the high prices are maintained.

BARROW-IN-FURNESS, 4TH FEBRUARY, 1891.

HEMATITE.—A quieter tone is reported in the hematite pig iron trade, and the necessity of restricting the output of pig iron has been recognised in the blowing out of a furnace this week at the works of the Workington Hematite Company. There are now only 44 furnaces blowing, compared with 50 at the beginning of the year. The accumulation of stocks has been checked, the increase this week having been only eight tons. The value of pig iron has declined, and is quoted to-day at 51s. 9d. for warrants net cash, while makers are asking 53s. 6d. to 54s. for mixed Bessemer numbers, and say they cannot sell for less with raw material at its present price.

STEEL.—There is less doing in steel of all descriptions, and none of the works have many orders. The outlook, in fact, is cheerless, and the number of spring orders will determine whether the mills will be well employed during the year. Rails are easier at £4 15s. for heavy sections. In shipbuilding material the trade is very quiet, and the only prospect of new orders is on local account. Plates are at £6 5s. per ton, angles at £5 7s. 6d., and boiler plates at £7 2s. 6d. per ton. Little is doing in tinplate bars, blooms, slabs, and billets, but a good trade is springing up in heavy forgings and castings, and in steel hoops.

MIDDLESBROUGH, 4TH FEBRUARY, 1891.

PIG IRON.—The iron market has been very flat during the past week, and prices generally were weak. There is little buying, and consumers are disposed to wait until the stock returns for January are issued. A large increase in stocks is expected—probably over 30,000 tons. Deliveries to Scotland have increased since the termination of the railway strike. Merchants quote 42s. per ton for prompt f.o.b. deliveries of No. 3 G.M.B., but buyers will not give more than 41s. 9d. Middlesbrough No. 3 warrants are about 41s. 10d. cash, but no business is done in them. Grey forge is in better request for Scotland, as well as for local consumption, and is sold at 40s. 9d. Local hematite is down to 54s. 6d. at works for mixed numbers, buyers offering 54s. The decrease of freights from Bilbao to 5s. 3d. per ton is in favour of the makers.

MANUFACTURED IRON AND STEEL.—The manufactured iron and steel trade remains unaltered. Iron ship plates are £5 15s. per ton; steel ship plates, £6 2s. 6d.; steel angles, £6 5s.; iron angles, £5 12s. 6d.; common iron bars, £5 15s., all f.o.b. at works, and less 2½ per cent. discount for cash on the 10th of the month following delivery. The angle trade, though dull, is better than the plate trade. Heavy steel rails are £5 17s. 6d., and chairs £3 15s.

IRONMASTERS' RETURNS.—These returns show a reduction of 34,019 tons in stocks of pig iron. The mine owners met the miners' delegates to-day. After some discussion it was agreed that a reduction of 5 per cent. in miners' wages should take place. This settles, so far, the anticipated crisis.

SUNDERLAND, 4TH FEBRUARY 1891.

SHIPBUILDING AND MARINE ENGINEERING.—The shipbuilding and marine engineering business of Messrs. William Doxford & Sons, Pallion, has been converted into a limited liability company, the shares being all privately subscribed by members of the firm and their friends. Three steamers of 6,202 tons have been launched during the last month. No fresh contracts for steamers have been entered into but one firm has secured an order for a sailing vessel. There are still complaints of delay in the delivery of material ordered from Scotch iron and steel manufacturers.

THE SHIPPING TRADE.—The general aspect is not promising. Outward freights to the Mediterranean have failed to maintain the whole of the improvement recently shown. Black Sea homeward business continues, however, to evince firmness, but the rates obtainable are scarcely remunerative to the great bulk of steamships now trading, owing to the high price of coal and the increased cost of labour. Coal shipments have improved locally, owing to the liberation of ice-bound tonnage, but are not satisfactory, largely owing to the continuance of the strike at Silksworth Colliery. Last week 65,804 tons were shipped, a decrease of 9,606 tons as compared with the previous week. Shipments for abroad continue very low, more than three-fourths of the total quantity going coastwise.

THE DARLINGTON FORGE COMPANY.—As an example of rapid execution of work, the following achievement is interesting. Early in last month this company received an order from Messrs. D. & W. Henderson & Co., Glasgow, for a single crank-shaft for the Allan liner "Corean," the dimensions of which were 5ft. stroke, 15½in. diameter, and 9ft. 4in. over all. The forgings for this shaft were commenced on the morning of the 5th ult., immediately on restarting the works after the New Year holiday stoppage, and the shaft was built up, turned, and finished ready for despatch by the 12th ult. Nothing was done to the shaft on the 10th ult., so that the whole of the work in connection with it was completed in five actual working days.

NEWCASTLE, 4TH FEBRUARY, 1891.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending January 31st amounted to 103,393 tons, being an increase as compared with the shipments in the corresponding week last year of 9,263 tons.

SHIPBUILDING PROSPECTS.—The steady increase in the number of steamers that are being laid up week by week, and the continued lowness of freights, tend to make the future outlook for shipbuilding very gloomy. Some elements, however, in the situation justify the hope that the depression will not be so severe as that of the year 1888. The necessity which is placed upon shipowners of replacing old vessels and engines of obsolete types by new ones, better suited to the requirements of the time, will prevent the extremity of slackness being reached which existed from 1885 to 1887. There is also the encouraging fact that foreign shipowning companies are well aware of the advantage of buying English tonnage to fill up vacancies in their fleets during the period of restricted trade and low prices. A good many foreign orders for both ships and engines are now in the market, and quite recently one such order has been placed with a well-known firm on the Tyne.

ENGINEERING.—Messrs. John Abbot & Co., who for a considerable time have been very busy in their iron founding department, have just turned out a large flywheel rim, the weight of which is said to be 17 tons. This is one of the largest wheel rims that have ever been made in the district. It is intended for the new steel rolling mills of Messrs. John Spencer & Sons, at Newburn, to which destination it will be despatched after having been machined at Messrs. Black, Hawthorn, & Co.'s works. Messrs. H. Watson & Son, of the High Bridge Works, have just completed the fitting of the electric signalling gear in the cruisers "Sirius" and "Spartan," now being built at the yard of Sir W. G. Armstrong, Mitchell, & Co. They have an order from the Palmer's Company for similar installations in the cruisers "Pique," "Rainbow," and "Retribution." The firm are also commissioned to carry out the fitting of the pumping arrangements in the two cruisers being built by Messrs. Earles, of Hull, and are busy in the foundry department with gun-metal castings required in the equipment of war vessels for the home and several foreign Governments.

LEATHER AND INDIARUBBER WORKS.—Messrs. John Taylor & Co., Dean Street, are very well occupied in both their leather and indiarubber departments, their engineering specialties in indiarubber goods being much sought after. The firm have just taken up the agency for the new roofing materials "Duroline" and "Carboline," which appear to possess advantages that are sure to obtain for them a wide acceptance in the future.

DUNDEE, 4TH FEBRUARY, 1891.

EXPORTS TO THE UNITED STATES.—According to the return issued by the United States Consul at Dundee, the value of the exports of all kinds from this port to the United States for the quarter ending 31st December, 1890, was $2,035,457·24. For the corresponding quarter of 1889 the exports were valued at $2,300,119·85, and for the same period in 1888 they were $2,101,302·90. It would thus appear that the McKinley tariff has not affected the exports from this district to any great extent.

TRADE WITH CANADA.—In the Canadian tariff plain, dyed, and coloured yarns imported by manufacturers of jute goods for use in their own factories are in the free list, as is also unfinished jute cloth imported by manufacturers of jute bags. Canvas imported by manufacturers of oilcloth and duck for belting and hose imported by makers of rubber goods are also free.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 76, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 6TH FEBRUARY, 1891.

THE EDUCATION OF ENGINEERS.

THE fact that such a question as "Is the study of thermodynamics of use to engineers?"—which is now being discussed in our columns—requires to be put, shows that the conditions and requirements of modern engineering education are still far from being understood. Of course these will vary considerably according to circumstances, and to the department of engineering which the student proposes to follow out, but there are some general principles which must be attended to in all cases. In the first place we must get rid of the idea that engineering is a single profession, and assume that it is a group of allied professions, all, more or less, closely connected with each other. These various departments of engineering have certainly a good many elements in common, but each of them requires a very large amount of special experience and training. No doubt there are many engineers who do good work in more than one department, but the tendency towards specialisation is increasing, and unless a man is a thorough expert in one department his general knowledge of several others will avail him little. A glance at the scope of the profession of engineering as defined by the Institution of Civil Engineers will show at once how thoroughly impossible it is for one man to study, far less to practise, all the branches therein enumerated. The programme includes methods of internal communication, such as roads, railways, tramways, and canals, telegraphs of all kinds, hydraulic works, relating not only to the sea-coast, but also to water supply for towns, and the irrigation and reclamation of lands. Architecture, both land and marine, and the operations of mining and metallurgy form part of the comprehensive programme. Moreover we find three sections which in themselves are capable of great variety, namely—(1) The design and construction of mechanical prime movers, such as steam engines, water-wheels, and other hydraulic motors, windmills, electric and other engines; (2) the design, construction, and adaptation to practical use of machinery and mechanical appliances of all kinds; (3) the design and manufacture generally of all large and important metallic structures, including artillery and other large articles of war.

The first thing, therefore, that a young man who wishes to become an engineer ought to do, is to form some idea of the department of engineering which he would like to pursue, and from the very outset he should give his training a certain amount of specialisation. For a year or two that specialisation need not be very pronounced, as a good general training in the principles and practice of mechanical engineering is serviceable to all classes of engineers, and provides a solid foundation for the special applications. One piece of advice, therefore, which we would give to intending engineers, is that whatever special department they may wish to pursue ultimately they should try to spend two or three years at least in a mechanical workshop in which a large variety of work is done. The old country millwright's shop, which has now almost disappeared, gave excellent opportunities for this kind of training. Referring to the school training of the future engineer, we are not by any means enamoured of some of the methods which are now being introduced. The aim of all school work should be to turn out good, healthy, manly boys, with active well-trained brains, which would enable their possessors to pursue almost any department of work with advantage. The old-fashioned high-class school was too exclusively classical in its tendencies, but it did much to preserve a healthy British spirit, which has really been the cause of our pre-eminence in so many departments. The modern school pays more attention to science and modern languages, and combines the training of the brain with that of the eye and the hand. A youth of 16 or 17 years of age who has gone through the curriculum of such a school, and wishes to become a mechanical engineer, and to follow the practical side of the profession, could not do better than go direct to a workshop for four or five years. He would there gain experience in the different departments, especially in pattern-making, fitting, and drawing office work, whilst at the same time he should attend evening science classes for two or three evenings a week. The majority of apprentices will get all they require in the way of theoretical training at such classes, and this, combined with their workshop experience, will have fitted them for some of the junior posts of their profession. Those who have displayed special aptitude for study might with advantage at the end of their apprenticeship attend for a year or so the day classes of a college or university, where they would have more time for the systematic study of some of the subjects which had previously engaged their attention. In some cases it may be found advisable to take a three years' course before apprenticeship, especially in the case of those who intend to take up the more theoretical side of the profession. It should not be overlooked, however, that a certain amount of workshop experience is of great service to college students.

It will be seen that, whatever plan be adopted, the practical training of the engineer is of as much, possibly of more, importance than the theoretical. The latter has, however, become very necessary by reason of the highly specialised state of knowledge. Moreover, modern machines are, in many cases, so complicated, that a good theoretical training is absolutely necessary, in order that their design, construction, and working may be thoroughly understood. True theory is, however, to be distinguished from abstract speculation, and is merely the condensed results of practical experience. It must be admitted, indeed, that in too many cases teachers of engineering do not seem to distinguish between such theory and their own hazy speculations, and thus they have brought discredit on college training generally. No subject has suffered from this method of treatment more than that of thermodynamics, about which some correspondence is now appearing in our columns. Its First Law, which enumerates the equivalence of work and heat, was too often misinterpreted, and false expectations raised as to the efficiency which might be expected from engines working under different conditions, until the bearings of Carnot's Law were recognised. But even that law has been strangely misused, by its application to cases entirely different from those from which it was derived. Without taking into account the limitations arising from the physical properties of the materials of construction and their influence on the action of the steam, it is impossible to make correct deductions from that law, or even to compare the efficiencies of two engines working

Digitized by Google

with different initial steam pressures and under dissimilar conditions. The object of such a treatise as that of Professor Cotterill is to show how results are modified by the conditions of actual engines and the causes of loss of efficiency. The investigations into the physical properties of steam and of gases, and their applications to heat engines, freezing and cooling machines, injectors, and other appliances, all attest the great value of the science of thermodynamics to mechanical engineers. It must be admitted that few improvements in the steam engine have been the direct result of thermodynamical investigations, but of an expensive system of experiment. Science has been used to illuminate these after they were achieved, rather than to point out the direction in which they lay. But this is largely the case in all sciences, as experiment almost invariably precedes a complete theory, and is, in fact, necessary to it. This order of discovery does not lessen the value of the theory, which enables experience to be condensed, classified, and compared. Little progress would be made if we did not profit by the experience of the past, and if we had not a means of explaining that experience. But the science of thermodynamics is now sufficiently advanced, not only to explain the difficulties of the past, but also to illuminate the path of progress in the future. The position of thermodynamics illustrates the uses of theory in all other departments of engineering, and shows the connection between theory and practice. Moreover, the intellectual training to be derived from the systematic study of a theory of heat engines is one of the results which must not be overlooked. Such a theory is a highly complex mathematical and physical problem, requiring earnest and persistent attention from the student, and can only be mastered by a mind which has been thoroughly trained, and which is, therefore, capable of continued exertion in almost every department of physical science.

THE SCOTTISH RAILWAY STRIKE.

The settlement on Thursday in last week between the North British Railway Company and its employés, and on Saturday between the Caledonian Railway Company and those of its servants then remaining on strike, brought to a close by far the most serious industrial crisis through which Scotland has ever passed.

The manner in which the men acted in leaving their work without notice was of course indefensible; but there can be no doubt that the conditions of railway service needed radical improvement. It is to this task that the directors and managers must now set themselves. The companies have met with the utmost forbearance from the traders and from the travelling public, who have suffered incalculable loss in consequence of the strike. The public thus only makes a fair claim in requiring that the companies shall do everything in their power to prevent such a crisis from occurring again. It is quite plain that if they do not spontaneously adopt drastic reforms in administration, a cry must arise to have these forced upon them. The short method of legislation has already been thrust into prominent notice. Though there seems no probability of a Bill being brought forward this session, it is likely that one or other of the proposed measures will be brought forward next year. Although Select Committees have a somewhat doubtful reputation, the inquiry to be set on foot by Sir Michael Hicks-Beach's Committee will probably be very useful, even to railway managers. But the safety of the service really lies, not in any extraneous and compulsory regulation, but in administration wise enough to render the railway service attractive to the best class of workmen. This can only be done by making the conditions of labour very much more tolerable than they have been. The immediate cause of the strike appears to have been that the conditions of labour on the Scottish lines were so bad that the quality of the staff had deteriorated.

The railway companies may find it difficult to make detailed administrative arrangements to reduce the working hours of their servants within normal limits; but if the wit of their managers does not extend so far, the public and themselves must expect to suffer for it. It is a very easy but very delusive expedient to lay the whole blame of such crises upon the paid agitator. In this case there is really little evidence of his having had much influence. The men, or the noisy sections of them, seem to have managed matters in their own way, largely in open defiance of their leaders. The railway companies seem distinctly to blame for having endangered the public safety by allowing the conditions of work of their staff to drift into a position in which there was an accumulation of grievances, perhaps petty in themselves, but in the aggregate intolerable to the efficient and alert servant.

This is the natural history of the strike; and, although the managers of the companies have secured a nominal victory, the causes of the outbreak will have to be removed, or another will inevitably occur. It is serious enough to reflect that the men returned to their work in obedience to moral rather than to material pressure, and that the actual loss to themselves in consequence of the strike was probably less than a tenth part of the loss to the companies, and less than a twentieth part of the loss to the public. There is by far too strong a suspicion in the minds of the public that, as regards rates, the railway companies have opposed their interests to those of the public, so as to be able to exercise autocratic powers over the large bodies of men they control. Any attempt therefore to apply to railway servants the rules in force in regard to servants of the State would inevitably encounter serious opposition. The most effective and elastic method is the method of spontaneous regulation.

It is natural that, at a time when the whole subject of railways is in a state of fusion, suggestions for the nationalisation of the railways should be made. It is to be pointed out, however, that what this strike has proved is, not the absolute failure of joint stock railways, but that defective administration is not confined to public departments. The fault has been, as shown, largely an administrative one. Dissatisfaction with long hours and other conditions of employment has produced strikes among State servants—among postmen and policemen, for example—and mutiny among soldiers. It is, indeed, in one sense, fortunate that our industrial armies are not employed on the same footing as groups of State functionaries, for a strike among workmen is not treason, and there is practically no risk of civil war, whereas a strike among the servants of a public department, produced perhaps by mere want of tact on the part of some subordinate or superior official, might bring us to the verge of a revolution. In the particular case in question, patient and far-seeing reform in administration is the practical remedy which must be applied. Only by wise, just, and sympathetic management can the railway companies hope to secure the high-class and reliable servants they require, and which it is a public necessity they should have.

JAPANESE FOREIGN TREATIES.

We have on several occasions referred to our commercial relations with Japan, and pointed out the desirability of our Foreign Office meeting the Japanese Government in a broad and liberal spirit as regards this question. Quite recently Viscount Aoki made an important speech before the Japanese House of Commons, in which he reviewed the treaty revision question historically, and described the manner in which the early treaties with foreign Powers were concluded, as well as the circumstances which forced the "disastrous" tariff convention of 1866 on the Government of that day. He discussed the effects of the most-favoured-nation clauses in the later treaties made by Japan with certain Western countries, which, he said, were most serious for the legislative and commercial autonomy of Japan. He then referred in detail to the various efforts made since 1872 to conclude treaties on new bases. Attempts to this end were made in 1871, when a special mission came to Europe, in 1875, in 1878, when a special treaty was signed with the United States, in 1880, 1882, 1886, and finally in 1888. Viscount Aoki drew special attention to the fact that the treaties were not permanent. The Government had in nowise abandoned the work; it had been established for twenty years past as one of the national duties, and no Government could give it up. At the same time other duties fell on the Foreign Office; they could not be devoting themselves day and night to treaty revision only, and it was a popular mistake to suppose that the foreign relations of the country were all summed up in those two words. Speaking of foreign commercial relations, he said that at their doors was a nation of 270,000,000 people ready to take their manufactures and products and to give its own in return. The Chinese were the proper partners of Japan in trade and industry. In olden times the Japanese manned their boats and harried the coasts of China; the descendants of those hardy mariners ought to have something better to do than lose themselves in contemplation of the two words "treaty revision." Large spheres of activity and of national development lay before them; and when the treaties were revised those would become much larger He could not agree that the tariff question could be separated from the judicial question; both must be dealt with together, and he hoped in regard to the codes of law, which wrecked Count Okuma's scheme, to make an arrangement which would meet with public approval. The revision of the treaties was bound to come; the present system was inconsistent with Japanese progress and independence, and it was in conflict with the constitution. Hence the Government had opened negotiations, the details of which, however, he refused to disclose. He would only say that so far the result was reasonably satisfactory.

ELECTRIC LIGHTING OF THE CITY OF LONDON.

A complete scheme for the electric lighting of the City of London has now been projected, and on the 3rd inst. the first stone of the main junction box, near the Mansion House, at which the mains of the two contracting companies are to be joined, was laid by the Lord Mayor. For the purposes of the scheme the City has been divided into three sections. For the lighting of the eastern section, which consists of the whole of the City east of the Mansion House, the contractors are the Laing, Wharton, & Down Construction Syndicate. The central section consists of that part of the City which lies between the Mansion House and St. Paul's Cathedral, and will be lighted by the Brush Electrical Engineering Company. The western section extends west of the Mansion House to Temple Bar, and will also be lighted by the Brush Company. All the streets of the City of London are to be lighted electrically, and 400 arc lamps of 2,000 candle-power and 1,000 incandescent lamps are to be used. The cost is estimated at about £20,000 per annum, and the amount of light will be twenty times as great as that obtained from the present gas supply. As already mentioned, the two systems are to be connected together, so that, in the event of the failure of one system, the other will be able to light the whole of the City. The central station for the western and central sections will be situated on the south side of the river, and that for the eastern section will be near the Custom House.

THE LATE MR. JOHN DIXON.

The death of John Dixon, civil engineer, on the 28th ult., removes one who was widely known and much respected. The eldest son of the late Jeremiah Dixon, of Bella Wrag, near Windermere, he came of a well-known family of coalowners and engineers at Crockfield, in the county of Durham, and was nephew of the late John Dixon, the first chief engineer of the Stockton and Darlington Railway, who was intimately associated with George Stephenson in the original surveys and making of this, the first, railway. Born at Newcastle-on-Tyne in 1835, he commenced his education at Dr. Bruce's school, and served an apprenticeship at the engine works of Robert Stephenson & Co. Soon after completing his apprenticeship he was appointed engineer at the Consett Iron Works, where his eminent abilities soon secured him promotion to the management of the old Bishopwearmouth Iron Works, which were a branch of this establishment. When these works were abandoned by the New Consett Iron Company he went into business on his own account, but, this venture proving unsuccessful, he removed to London, where he began a succesful career as engineer and contractor, which was carried on till his death. In this capacity he carried out many important works in various parts of the world. In 1874 he got the concession for and made the first experimental railway in China, from Shanghai to Woosung, which was very successful and popular among the natives for a time, but, owing to the prejudices of the ruling mandarins, was shortly bought up and the materials taken out to sea and sunk. His discovery of an unexpected supply of water in the Rock of Gibraltar and his practical demonstration of it were due to his great knowledge of geological science, and brought him into high repute with the military authorities and the War Department, who purchased his concession, and thus established an invaluable constant supply of fresh water. His next enterprises were in Portugal, where he constructed the Custom House piers at Lisbon and a 60-mile line of railway, and where the confiscation and tardy payment by the Government required the intervention of our own Foreign Office and the suspension of a Government loan on the Stock Exchange before honest payment could be enforced. The rebuilding of Hammersmith Suspension Bridge over the Thames was his next work. But the work of all others which brought him most repute was the transport from

Digitized by Google

Alexandria to London of the famous Cleopatra's Needle, which is now a familiar object on the Thames Embankment. In this enterprise he was supported by the late Sir Erasmus Wilson to the extent of £10,000, but owing to the unfortunate salvage claims, he was financially a loser to almost the same amount. Failing health some three years ago induced him to visit our colonies in South Africa, where his reputation as a harbour engineer caused his opinion to be sought in many important harbour works; but, broken down in health, he never thoroughly rallied after his return, and he died at the comparatively early age of fifty-six.

THE LATE MR. ROBERT F. MUSHET.

Mr. Robert Forrester Mushet, who died at his residence at Cheltenham on the 28th ult., was the remarkable son of a remarkable father, both of them having left indelible marks on the history of the iron and steel industries of the world. The father, David Mushet, was perhaps the most advanced metallurgist of his day, and in his well-known work, entitled "Papers on Iron and Steel," showed that he possessed an appreciation of the importance of these manufactures and of the conditions of their development that was very rare at the time when he wrote. He was of a practical as well as a philosophic turn of mind, and for a number of years he acted as the manager of some of the most important works in Scotland. Here young Robert was born, about eighty years ago, and, although the son did not enjoy the advantages of a very high-class education, as that would now be understood, he learned a great deal of the practical working of mines and furnaces from his father, who was something of a chemist, a geologist, a mining engineer, and a blast furnace manager combined. The young man was, however, of a more strictly scientific turn, and was no doubt a better all-round metallurgist than the father, having lived at a time when science was much more appreciated than it was a hundred years or so ago.

The original discoverer of the famous black band ironstone of Scotland was Mr. David Mushet, the father of the gentleman who has just died. This discovery was made about the year 1800, when the iron trade of Scotland was on a very limited scale indeed. Twelve years previously, according to David Mushet's well-known "Papers on Iron and Steel," there were in Scotland only eight blast furnaces, making between 6,000 and 7,000 tons a year of pig iron as a whole, while the finished iron industry was restricted to one forge and three refineries, which turned out about 240 tons of bar iron annually. From this period onwards, for many years, the quantity of iron produced in Scotland was doubled about every ten years, and one of the chief factors in the development that took place was the supplies of iron ore placed at the disposal of the iron trade by Mushet's discovery, aided by other factors of progress, of which the most important was Neilson's application of the hot blast to smelting. Until recently the make of iron from the local ores of Scotland, mostly black band, has averaged from 500,000 to 600,000 tons per annum, but this source of supply has of late years become largely exhausted, and foreign ores, as well as other local ores, have had to be called into use in increasing quantities.

David Mushet was also known as the patentee of a process for the manufacture of cast steel, which, in a modified form, was long carried on at Sheffield, and which, in its day, enjoyed a considerable reputation. The process, as originally introduced, is stated to have consisted "in fusing malleable iron, in the form of bar or scrap, or iron ore, when sufficiently rich and pure, in crucibles, with the proper quantity of carbonaneous matter." By varying the proportions of carbon different qualities of steel could, of course, be made. So-called Mushet steel has, of late, become identified with alloys of tungsten and wolfram, but there were really two distinct Mushet steel processes, and the latter process was for some time carried on by Mr. R. F. Mushet at Coleford. It is interesting to learn from Dr. Percy that David Mushet is stated to have disposed of his steel process to a firm in Sheffield for £3,000—a strange contrast to the rewards that have subsequently awaited Bessemer, Siemens, and other inventors.

The most interesting phase of the career of Mr. R. F. Mushet is undoubtedly that which connects him with the Bessemer process. Bessemer's first patent was dated 17th October, 1855, and his invention was stated to consist in "forcing currents of air or of steam, or of air and steam, into or among the particles of molten crude iron, or of remelted pig or refined iron, until the metal so treated is thereby rendered malleable, and has acquired other properties common to cast steel." A second patent for "improvements in the manufacture of iron" was obtained by Bessemer in the same year, and the aim of this patentee was stated to be "to form ingots suitable for puddling." The refinement of pig or crude iron was spoken of in the same patent as carried out "by a single process," and this process "cast the same into ingots suitable for rolling at once into bars or rods." In February of the following year a third patent was taken out, the object being "to convert into steel or into malleable iron, without the use of fuel for reheating," crude pig iron. Bessemer obtained further patents on the 15th of March and on the 31st of May, 1856, the objects of which were to secure modifications of his apparatus.

Up to this time the Bessemer process was incomplete. The radical defect from which it laboured was that the exact quantity of carbon required to produce steel could not be properly regulated, so that there was great uncertainty in the product. Bessemer was fully aware of the defect, and laboured hard to remedy it. He seemed, in his own mind, to have almost reached his goal, as a result of experiments made with metallic manganese—formerly employed in the casting of steel by Josiah Marshall Heath as an alloy—when Mushet obtained, on the 22nd of September, 1856, a patent for the addition of molten spiegeleisen to Bessemer's decarburised metal while still in a state of liquidity. This simple expedient made the Bessemer process complete. Instead of groping in the dark to ascertain the point of when decarburisation had proceeded to the required degree, Bessemer was now able to use the system that has since then been universally adopted, of first completely decarburising the metal in the converter, and then adding a given proportion of carbon in the condition in which it exists in molten spiegeleisen, so that, to quote the high authority of Dr. Percy, "spiegeleisen has given a value to Bessemer's process of making steel, which certainly it did not previously possess." This verdict has been endorsed by many subsequent writers on the subject, and it is probable that Sir Henry Bessemer would admit its substantial accuracy. Next to Bessemer himself, it is probable that no man, either living or dead, has been so prolific an inventor and patentee in connection with the manufacture of steel as Robert Forrester Mushet. Between March, 1859, and December, 1861, he took out thirteen patents for so-called improvements in the manufacture of iron and steel, all of them having more or less reference to the application of titanium as an alloy. An abstract of these specifications will be found in Dr. Percy's "Metallurgy of Iron and Steel," where it is remarked that "Thirteen patents to one man for the application of titanium in one form or other to the manufacture of iron and steel is a somewhat remarkable incident, even in the annals of patentism!" The learned doctor proceeds to state that, in spite of the fact that Mr. Mushet had proclaimed far and wide the "unrivalled excellence" of his titanic steel—articles of titanic steel having been profusely displayed in conspicuous shops, with large sideboards, in London, Birmingham, and elsewhere—some analytical chemists of skill and repute had declared their inability to detect any titanium in this steel, while Mr. Mushet had not succeeded in convincing the Sheffield manufacturers of the great merits claimed for his special description of metal.

Mr. Mushet took out several patents for the application of tungsten to the manufacture of cast steel. "Tungsten," says Dr. Percy, "tungstic acid, or oxides or ores of tungsten, are all appropriated by this gentleman, but wolfram is preferred, because it costs less and contains manganese, which facilitates fusion."

For a number of years past Mr. Mushet has lived in practical retirement at his favourite place of residence—Cheltenham, and has withdrawn from all active participation in business affairs. He has, however, every now and again come forward to communicate in the technical press his opinions or his experience relative to matters that were in dispute in the metallurgical world, and his remarks have always been received with respectful attention. He had, in some cases, a disputatious habit that did not tend to make him very agreeable with those from whom he differed; but he was, nevertheless, a man of warm heart and catholic sympathies. For the last sixteen or seventeen years of his life he suffered from ill-health; and when, even so far back as 1873, the Iron and Steel Institute presented him with the Bessemer Gold Medal, in acknowledgment of his services to steel-making, he was in such an infirm condition of body that he declared himself to be unable to make a journey to receive it. On that occasion Sir Henry Bessemer himself endorsed the action taken by the Iron and Steel Institute. Mr. Mushet's services to the steel manufacture have been differently regarded by different people, but owing to the failure of some of his friends who were left in charge of the payment of the necessary fees, the spiegeleisen patent was allowed to lapse, and he failed to receive any pecuniary benefit from it. It was under these circumstances, and while he was still being threatened by Mushet with proceedings that might have seriously crippled the value of his process, that Sir Henry undertook to make Mr. Mushet an annuity which he has paid regularly ever since.

Letters to the Editor.

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—Your correspondent, "Londoner," cannot have any practical acquaintance with the subject on which he writes. If he will take the ordinary "asbestos radiators, which are white," and colour them black, he will find that the appearance and effective duty are both seriously reduced although the material remains the same, and he will also find that no black is known which is permanent at a red or white heat.

With regard to the draught caused by gas fires, it is a very simple matter indeed to partially close the outlets until they are correct for each individual case. No fixed area of outlet for products of combustion will suit all cases, and, therefore, the safest method is to make the outlets amply large for a sluggish draught and let the fitter close this as much as is required.

Yours, &c.,
Thos. Fletcher.

Warrington, 31st January, 1891.

To the Editor of "Industries."

Sir,—As a Londoner *pur sang* I am constrained to beg of you space in which to say a few words on Mr. Thwaite's colossal scheme.

In his original articles he very graphically sketched the danger and discomfort to which both weak and strong are subjected whenever a fog of any density occurs, and he has also indicated the monetary loss resulting from the same cause. This last item I would especially emphasise, as I am convinced that an adequate appreciation of the fact that they are suffering pecuniary damage is more likely to lead any body of Englishmen to adopt methods of reform than any other means with which I am acquainted. Perhaps the greatest source of actual loss is the waste of time caused by the disorganisation of ordinary traffic by road, river, and rail to which all those compelled to travel on a foggy day are inevitably subjected.

The vast size of London, and its frequently objectionable atmospheric conditions, have forced most professional and business men to live some considerable distance from their work, and to be under the necessity of depending upon some one or other of the methods of conveyance I have indicated in order to reach it. When a fog comes they are detained on their journey for periods of time that in many cases are not to be reckoned by minutes but hours. Were it possible to estimate the loss caused by this delay, both by actual shortening of the time available for the despatch of business and by the impossibility of adhering to that economic distribution of his time which every busy man strives to make, as well as the less tangible but even more important worry and irritation engendered in all but the most phlegmatic, by such conditions, I opine that the total would astound its computer, and make the cost of preventing the occurrence of these inconveniences appear relatively trifling, if not negligible.

These arguments will have additional weight when it is remembered that the misery entailed by a fog falls most heavily upon those possessing what used to be known as "the nervous temperament"—that is to say, those that are the salt of the earth, by whom alone it is kept tolerably sweet. The survival of the fittest here has its best exemplification; the fittest do survive—the fittest, that is, to exist in a fog, which, indeed, may be considered their natural habitat. Thus there seems little reason to deem Mr. Thwaite's scheme impracticable because of its money cost; money will be forthcoming in plenty, provided a reasonable prospect of a good dividend can be held out. It is on this side that we need further information. No method of financing the proposed undertaking has at present been suggested. I presume it is contemplated to carry out the plan by means of an ordinary public company in the usual way; if this be so, it is imperative to bring forward evidence that the scheme will be far from unprofitable. Considering the freedom with which investors part with their money to the shadiest concern that is adroitly promoted, there should be little difficulty in floating one intrinsically sound.

Descending from generals to particulars, it would certainly seem expedient, as materially reducing the amount of capital required, to adopt the "alternative scheme"—*i.e.*, leave the existing gas companies untouched. In spite of the cost of carriage, gas can be, and is, produced fairly cheaply from coal carbonised in London, and much domestic smoke might be done away with by using it more freely in place of coal. This naturally brings me to another subject, which, though intrinsically a detail, must be settled, and satisfactorily settled, before there is any hope that the general consumption of gas will come about. It is the question of the best means of heating by gas.

I must protest most strongly against the proposition made by your correspondent, "R. S.," and endorsed by Mr. Thwaite, that gas should be burnt in the basement of the house it is to warm, "and be a source of heat to the whole building" by the use of water or air as an intermediary. Mr. Thwaite fears "that we shall not readily overcome the insular prejudices of Englishmen in favour of the open and cheery fire, whether of coal or gas;" I most sincerely wish we never may. The system of heating by *convection*, instead of by *radiation*, is radically wrong. In the first case, the *air* in a room is warmed, and the occupants of the room are supplied with an atmosphere which is about as agreeable to breathe as tepid champagne or chilly claret is to drink, and infinitely less healthy. Such warm air is frequently loaded with moisture, which it promptly deposits on all objects colder than itself—that is to say, on everything in the room. The laboratory from which I write was originally heated by hot-water pipes, and the amount of condensation on every solid body in the place, from balances to bottles, was an unmitigated nuisance. The substitution of gas fires has improved matters, as far as improvement is possible, where much gas is burnt in the open room, and water baths and evaporating basins are constantly in use. Heating by hot air, whether it be derived from the surface of hot-water pipes or be directly heated, is only fit for large buildings occupied for, at the most, a few hours at a time, and for such places as halls, lobbies, and staircases, through which people pass, but in which they do not stay.

It may be freely conceded that heating by gas fires (which, by the way, I may tell "Londoner," are now made in many better

Digitized by Google

forms than those he quotes) in the place of coal fires, is less economical than heating by hot air, but where it is considered of importance to utilise the whole number of heat units that can be formed by the combustion of the gas, the two methods can be combined, and the products of combustion, after heating the radiating material, may be allowed to expend the rest of their heat in warming the air of the room directly by means of ordinary arrangements of flues, such as are already in use for such purposes.

In conclusion, I may say that, in my opinion, Mr. Thwaite's plan is deserving of the closest attention, and its realisation would be the greatest boon possible to confer upon London, but that its benefits would be dearly bought were the unwholesome and irrational system of heating by hot air adopted.

Yours &c.,
B. B.

London, 3rd February, 1891.

To the Editor of "Industries."

Sir,—Referring to Mr. B. H. Thwaites' admirable articles in your issues of the 9th and 16th January, one is tempted to plunge into the discussion of such a subject in a most lavish manner, since there is so much that may be considered and so much that may be said.

With the prospect of possible enormous advantages to the general health, and not least that which would be felt by the middle classes in their continual warfare with domestic servants, any scheme promising such merits the greatest attention.

What appears to be most impressive is the conveyance of gas under pressure by pipe lines, the magnitude of which has hardly been hinted at. To displace fires in the metropolis alone, it seems quite conceivable that $\frac{1}{5}$th of a billion cubic feet of gas would have to be provided for in these mains. But would not these have to be tapped on their way for all the large towns adjacent to its course? For I have no doubt when once the convenience of an enormous saving of domestic labour by the use of gas for heating and cooking purposes is experienced, that the demand will extend to towns which have never suffered from the plague which it is the main object of this scheme to dispel.

The author of the articles has also apparently ignored the different values which the bye-products would have when produced in another part of the country. Is it not possible, therefore, to produce water and illuminating gas locally on a gigantic scale without the production of the pernicious smoke and gases which domestic fires at present evolve? Gas works are not, I believe, notorious for producing smoke, and there is a popular impression that their vicinities are not by any means unhealthy.

My suggestion for local gas works is in view of reducing the immense cost, practical difficulties, and leakage, due to the enormous gas mains proposed. By reducing the magnitude of this gigantic scheme I am of the opinion that it will receive greater support from a commercial point of view, and it is not likely in the present day that we shall find philanthropists who will take the burden of this project.

I wait to hear the views of others upon this matter, and trust that you will place your columns at the disposal of correspondents for some time to come.

Yours, &c.,
James Armer.

11, Queen Street Place, London, E.C.,
3rd February, 1891.

To the Editor of "Industries."

Sir,—Nothing could be much worse than our present method of consumption of coal, and any one who has taken the trouble to inquire into the effects produced by our smoke and sewage laden atmosphere, must be fully convinced that the present state of things cannot be allowed to continue.

It is not, I take it, at the outset, so desirable to find objections to Mr. Thwaite's proposal (for these may be easily brought against any proposal) as to compare it with rival schemes and with the present system, and to ask how far it will enable us to grapple with the problem, for which a solution must be found. We are face to face with a great plague, and one that the present generation have unfortunately grown up with and learned to tolerate, but which none the less carries off its victims by thousands annually. Mr. Thwaite's scheme, if carried into execution, will undoubtedly clear the atmosphere, and when this is done, the harm from sulphurous acid, organic matter, micro-organisms, &c., will be minimised.

But why does not Mr. Thwaite place his ideas before us here in Manchester? Here we have the coalfield at hand, and the Corporation has full control of the gas supply, whilst, as to the state of the atmosphere, London is comparatively a paradise. To speak from a .sanitary point of view: During the recent fog our deaths from diseases of the respiratory organs alone rose from a normal of 60 to nearly 170 in a population less than one-tenth that of London. That is to say, our normal death-rate from such causes equals the panic rate for fog in London, whilst the deaths in London from respiratory diseases in that dreadful Christmas week, instead of being 800, would have been at our rates 1,800! Our death-rate from the effects of fog and its accompaniments is understated if it is placed as *equivalent to the total death-rate of London!* And this to say nothing of widespread sickness and disorganisation.

Equally striking is the fact that whereas normally the births exceed the deaths by about fifty per week, they fell 169 below in that fatal week, and for the five fog weeks of December and January, instead of our population being increased by 250, it was actually diminished by 200. We are doing what we can to get at the root of the matter here, and to bring the public to recognise the nature of the devastation which the condition of our atmosphere is inflicting upon us.

Of one thing we are already convinced, that no amount of pressure (I had almost said coercion) put upon works and factories will do more than remedy a tithe of the mischief, and that any scheme which does not deal with dwelling-houses also may be at once rejected without further examination as worthless.

Yours, &c,
G. H. Bailey.

The Owens College, Manchester,
3rd February, 1891.

OUR BIG GUNS, AND HOW THEY ARE MADE.

To the Editor of "Industries."

Sir,—Your correspondent, "Yankee," has taken a meaning out of my letter which I did not wish it to convey. I ought, perhaps, to have said "that the method suggested by Sir William Siemens, and which had been previously carried out by the Government of the United States" in the manufacture of cast-iron guns, &c., but those who knew anything of the history of gun making would not suppose that I could mean that Rodman's method was due to Siemens. Your correspondent's insinuation about my wish to advertise the name of Siemens is quite gratuitous, as I had no such wish, and I have no connection either direct or indirect with the Siemens interest.

Yours, &c.,
C.E.

London, 31st January, 1891.

PRIVATE BILL LEGISLATION.

To the Editor of "Industries."

Sir,—The subject of "Private Bill Legislation," discussed in your article of last week, is one which, as you remark, has many aspects, and is leading to the expression of a great variety of opinions throughout the country. You have given some of these, but a few others may be mentioned. At the Dundee Town Council last week a report was submitted with regard to the Bill, stating that it did not touch one of the greatest evils in the present system—namely, the initiatory expenses attending petitions for and deposits of Bills. Further, that the new body would increase instead of reducing the cost of opposed Bills, while it would at the same time burden Imperial taxation with the salary of an appointed Commissioner and the expenses of all Sub-Commissioners, and with the rent and other expenses of an Edinburgh office, with its staff of officers, clerks, and messengers. The report concluded by stating that, in the interests of the public, the proposed Bill ought to be postponed, and that, as it at present stood, it would not work any good, but might produce evil; and the clerk was instructed to send a copy of the report to members of Parliament and the various local authorities in Scotland.

The Dublin Chamber of Commerce has also been considering the measure, and several objections were taken to it. In the first place, it was pointed out that the Commission would not be a permanent one, being appointed from year to year, and that one of its members was to be a member of Parliament. Now, if this Commissioner was a valuable member of Parliament, he ought to be left to attend to his Parliamentary duties, and not have his constituency practically disfranchised; if he was not a good and valuable man, he ought not to be put on the Commission. The opinions were further expressed that the expenses connected with private Bill legislation would not be reduced, and in many cases might be increased, and further that, if a Commission were to be appointed, it ought to be a permanent one, and have power to promote Bills at any time.

I think, moreover, that the custom of appointing judges to act in such matters concerning public opinion or expediency, as is suggested in the present case, one of the Lords of Session being nominated as a member of the Commission, is altogether wrong in principle, as it is a mistake to mix up judicial with what are practically a combination of legislative and executive functions. I am of opinion that Mr. Campbell Bannerman was right when he suggested that the powers of local bodies should be increased as regards those measures of purely local interest, so that they need not come before Parliament at all, while the larger and more important measures might be considered in a manner somewhat as at present, but simplified and cheapened in some respects.

Yours, &c.,
Lex.

Glasgow, 2nd February, 1891.

CYANIDE OF POTASSIUM AS A SOLVENT OF GOLD AND SILVER.

To the Editor of "Industries."

Sir,—Your correspondent, Mr. Andreoli, tries with great pains to make it appear that the "MacArthur-Forrest process" of gold extraction has been well-known since 1805! How is it that it is only after the proprietors of these patents have put them into successful operation on a large scale, and at a cost allowing a handsome margin to all concerned, that our learned friends come round and tell us how well they knew and understood all about it long ago? Not very long ago some experts, assumed to be competent to judge, prophesied nothing but failure and collapse!

It will probably be generally considered that a scientific and industrial periodical is scarcely the place in which to discuss the validity of patents, but as you have allowed Mr. Andreoli to commence such a discussion regarding the MacArthur-Forrest process, perhaps you will permit me to reply that the "Cassell Gold Extracting Company," Glasgow, who have the control of these patents, granted wherever applied for in the principal European countries (including Germany), the United States, the British Colonies, &c., after the most thorough search, have satisfied themselves of their validity, and mean to protect their valuable property.

Yours, &c.,
John S. MacArthur,
Technical Manager of the Cassell Gold Extracting Company, Limited.

157, West George Street,
Glasgow, 3rd February, 1891.

IS THE STUDY OF THERMODYNAMICS OF USE TO ENGINEERS?

To the Editor of "Industries."

Sir,—The question, "Is the study of thermodynamics of any use to engineers?" was a very natural outcome of the course of miscellaneous and contradictory reading to which "Student" had subjected himself, and his request that practical engineers and students of thermodynamics should point out the bearings of the subject on the work of the makers of heat engines is quite legitimate.

He must perceive, however, that if he wishes an answer which will show all the practical uses of thermodynamics, he must not expect to find it within the limited space of a letter. He must not only pursue his studies by means of the ordinary text-books, which can only give an introduction to the subject, but must continue them in the Transactions of engineering societies and in technical journals, where he will find their applications to the practical problems which an engineer requires to solve.

Mr. Bodmer's letter in your recent issue is a very good reply to the general question, and his recent articles which appeared in *Industries* on "Steam Engine Economy" should be read by "Student" as illustrations of some of the uses of thermodynamics to practical engineers. The recent experiments by Messrs. Willans and Muir, Major English, Professor Kennedy, and many others, all bear on the same point, while those of Hirn, Clausius, Dwelshauvers-Dery, Cotterill, Isherwood, Emery, &c., advance the earlier investigations of Rankine by a good many stages.

Mr. Bodmer does well to point out that such questions as those put by "Student," and such criticisms as appear in the *Engineer*, arise from a misconception of the purpose and scope of technical education, which is not meant in any way to supplant the practical discipline of former days (although it may shorten the wasteful drudgery), but rather to supplement the training which apprentices obtain in workshops. Even in the best establishments, that training is so one-sided that it is utterly impossible for any one to obtain a fairly good knowledge of the different departments of engineering unless it is supplemented by other studies, and, if possible, experiments. Moreover, no amount of workshop experience, by itself, would enable students to understand the action and the causes of high or low efficiency of modern heat engines. That can only be done by a study of the principles of thermodynamics.

It must be admitted that thermodynamics, like almost every other subject, has often been taught in such a manner as to lead to very erroneous ideas on the subject, but that is the fault of the teacher, not of the subject. The relation of the science of thermodynamics to practical steam engineering, or, more generally, heat engineering, is almost analogous to that of the science of political economy to practical politics. It is long since John Stuart Mill—we might also say Adam Smith—pointed out that there are few practical questions, even among those which approach nearest to the character of purely economical questions, which admit of being decided on economical grounds, and that when we apply political economy to the solution of practical questions we find it inseparably intertwined with many other branches of social philosophy. Political economists are only beginning to fully realise this, and to avoid being dogmatic when applying the results of their speculations to practical politics; so also writers on thermodynamics are becoming more careful in the application of results which have been deduced from ideal conditions to engines which are working under quite a different set of conditions. They must carefully examine the circumstances which modify the results, and this is precisely what Professor Cotterill has done in his valuable book, the review of which started the correspondence on this subject.

Professor Cotterill's book may be considered a treatise on the physics of the steam engine, and although in some points it is rather apt to run into details which are of more interest to the physicist than to the practical engineer, on the whole it is a most satisfactory production. I admit that the text-book on the steam engine, founded on the principles of thermodynamics and on practical experiment, has still to be written, although several books—curiously enough, chiefly from the Continent and America—have approximated to what a well-educated engineer would consider good treatises on the subject. In your columns, for instance, you have reviewed De Volson Wood's book on "Thermodynamics, Heat Motors, and Refrigerating Machines," and Peabody's "Thermodynamics of the Steam Engine," and while giving these their due share of praise, you have pointed out what practical engineers at once observe to be their defects. I mention these books, however, chiefly for the purpose of referring "Student" to their "Tables of Contents" for a reply to his question. If he considers for one moment what would be the position of any of the numerous subjects therein enumerated without thermodynamics he will have no difficulty in admitting that its study is of great use to engineers.

Yours, &c.,
Henry Dyer.

Glasgow, 2nd February, 1891.

Reviews.

Absolute Measurements in Electricity and Magnetism. By A. Gray. London: Macmillan & Co. 1890.

The teacher of electricity who wishes to impress on his pupils that "science is measurement" could hardly find a text-book better suited for this purpose than Professor Gray's "Absolute Measurements in Electricity and Magnetism." The student will find in it a clear definition of the various absolute units used, minute accounts of the methods of determining them, and careful descriptions of the instruments used in measuring electrical and magnetic quantities in terms of them. Besides this the book abounds in practical hints respecting the minutiæ of laboratory work which make all the difference between accurate and worthless experiment. To include all this, together with no inconsiderable portion of the theory of electricity, in a moderate sized volume of very legible print, Mr. Gray has carried compression of style almost to its utmost limit, and the reader who has no taste for what Professor Huxley calls "intellectual pemmican" will find it difficult to finish the book. Sometimes this is carried to such a point that the meaning is really obscure—for example, the ordinary reader would infer, from the statement on page 85, that a battery arranged to give maximum

Digitized by Google

current through a given external resistance is joined in multiple arc. The student of science should be, above all things, patient, but his patience will be severely tried by the frequent occurrence of the reference, "*see below, p.* —." On comparing the present edition with the former, we find many changes and additions which add considerably to the value of the work. Sir William Thomson's graded galvanometers, which were fully described in the earlier edition, are now replaced by his current balances, but the description of the method of graduating them is retained, with slight verbal alterations, and applied to voltmeters in general. The meaning of parts of this description is clearer when read as referring to the potential graded galvanometer. The account of Mr. Thomas Gray's experiments for the determination of H at Glasgow, in 1885, is also new and extremely interesting. The student will find in these experiments a model of careful and accurate laboratory work.

We have noticed a few misprints in the book. On page 45 the reference "(p. 72)" should be "(p. 73)," and we are still in the dark as to the meaning of "equations (11.) or (12.)" on page 148; perhaps equations (1.) or (2.), Chapter IV., are meant. We regret that Mr. Gray should lend his authority to the barbarism "ohmic resistance"; as well say "yardic length" or "quartic capacity." "Current strength," also, is almost as loose an expression as "rate of speed." On the vexed question of units, Professor Gray takes up a reasonable position of impartiality. He does not, like Professor Garrett, tell us that [L] is not a number; on the contrary, by adopting Professor James Thomson's term of *change ratio*, he implies that it is one, and he explains in a note that he only uses such expressions as "the product of mass and velocity" to avoid "intolerable prolixity." Still, he hankers after the suppressed dimensions of Professor Rücker, and when, on page 71, he states that "we may with propriety speak of a resistance of one ohm as a velocity of 10^9 centimetres per second," we can only reply that our sense of "propriety" differs from his.

In the preface to this edition the author gracefully acknowledges his indebtedness to Sir William Thomson, and no one can dispute that, in the text, he has done his utmost to discharge his debt.

TREATISE ON THE EVAPORATION OF SACCHARINE, CHEMICAL, AND OTHER LIQUIDS, BY THE MULTIPLE SYSTEM IN VACUUM AND OPEN AIR; also, THE CONSTRUCTION AND WORKING OF THE DIFFERENT SYSTEMS. Compiled by James Foster, M.I.M.E. Published by THOMAS REED & Co., of Sunderland; SIMPKIN, MARSHALL, & Co., London; and E. & F. N. SPON, London and New York. 1890.

The question of economical evaporation is, at the present time, one of such great importance in many branches of industry, that it is a matter of surprise that no attempt has hitherto been made to gather together and systematise the numerous articles relating to the best and most successful system of evaporation—viz., that accomplished by what is known as the multiple effect. Owing to the fact that the principal employers of vacuum apparatus in connection with the manufacture of beetroot sugar are to be found on the Continent, the literature of the subject is almost entirely confined to foreign languages, and exists, therefore, in a form not readily available to ordinary readers. Even those who have a fairly good acquaintance with continental languages are apt to be easily misled by some unfamiliar technical word or mode of expression cropping up from time to time. As the inherent technicalities of the subject are sufficiently trying, without being aggravated by linguistic difficulties, it is a matter of congratulation that Mr. Foster has been able to give the substance of the most important of these memoirs in our own language.

The work may be said to almost entirely consist of extracts from treatises by Horsin-Déon, Hugo Jelinek, E. Peclét, Francisco Sach, E. J. Maumené, and Payen. It also contains complete specifications of recently invented multiple evaporating apparatus, and numerous tables and useful notes relating to the subject. The matters alluded to, together with their accompanying illustrations, which are exceedingly well engraved, form almost the entire volume. These extracts appear to be carefully selected, and are, in the main, very well translated, and the author has added to the value of the work by acknowledging the sources of his information, and by furnishing a good table of contents.

In his anxiety to please those connected with the manufacture of sugar, who will probably form the most numerous class of his readers, the author has occasionally introduced articles from the above-mentioned writers which have comparatively little bearing upon the immediate subject of his work, such as those relating to the manufacture of beet sugar, and the general plant and processes employed in beet and cane sugar factories. These details are to some extent old, and in addition to being out of place do not do justice to the present position of fabricants and refiners.

These defects, however, are far more than counterbalanced by the inherent merits of the work, which can be strongly recommended to all those who are interested in the important subject of which it treats.

METAL TURNING. By a Foreman Pattern Maker. London: WHITTAKER & Co. 1890.

The author of this book, in his preface, says that his ability to prepare such a work will probably be conceded by readers of his other works. This at first sight seems rather egotistic, but as we have read and reviewed his books we are willing to admit that it is correct. The book does well what it professes to do, its aim being to explain and illustrate the practice of plain hand turning and slide-rest turning as performed in engineers' workshops. The author's experience has been well fitted to qualify him for writing this book, since, as he informs us, he has been constantly employed as apprentice, workman, and foreman in an engineer's factory during a period of twenty-nine years. He has thus become familiar with all the departments of an engineer's work, amongst which metal turning is one of the most important. We need not enter into details of the book, but may mention that after explaining the construction of the lathe and its different parts, descriptions are given of the tools, tool angles, and chucks, and the methods of using them. After some general remarks on turning, there is a chapter devoted to hand turning and another to slide-rest turning, while the two last are devoted to boring and screw cutting. The last especially seems very complete, and explains very fully the method of cutting screws, and gives a number of examples of the calculations required, while an appendix contains some useful tables. We think the author's good opinion of his work is fully justified.

WATER PURIFICATION FOR MANUFACTURERS AND STEAM USERS. SAWREY & COLLETT. 1890.

This is a useful short description of the injurious effect of using hard waters in boilers and the remedial measures usually resorted to. Manufacturers and steam users are frequently ignorant on these subjects, and either do not have their attention drawn to the condition of their water supply until some disaster has taken place, or listen to the advice of some travelling agent with one of the many worthless secret compositions sold as specifics against boiler incrustation. Although the present notes have been compiled with the object of pointing out the advantages of the Stanhope Company's system of softening and purifying water, they discuss the subject in a straightforward and useful way, and do not unduly advocate this well-known system of purification. We can recommend a perusal of this little volume to manufacturers and others who are not satisfied with their water supply, as it will no doubt give them a simple explanation of their difficulties, and put them on the right way for improving their service. In many industries—*e.g.*, tanning and bleaching—the advantages of a soft water are too well known to need any repetition here, but it is often in the smaller industrial operations that the economy to be derived from a local softening of the town supply is overlooked.

CHEMICAL ARITHMETIC. Part I. By W. Dittmar, LL.D., &c., Professor of Chemistry, Glasgow and West of Scotland Technical College. Glasgow: WILLIAM HODGE & Co. London: WILLIAMS & NORGATE. 1890.

This book, in a certain sense, is a new edition of Professor Dittmar's "Tables to Facilitate Chemical Calculations," but the changes and additions have been so numerous as to practically make it a new book. It consists of a collection of tables and formulæ intended for the use of chemists and others, and will be completed by a second part containing an exposition of the applications of arithmetic to chemical problems. The object in the present part has been to offer to the scientific as well as to the technical chemist a fairly complete collection of what he needs of mathematical auxiliaries, and of chemical and physical constants, in the ordinary routine of his laboratory work, and that without going further. The book, therefore, does not pretend to compete with works of the order of Clarke's "Constants of Nature," or even of Landolt and Börnstein's "Tabellen," nor is it intended to supplant books which, like Lunge and Hunter's "Pocket Book," address themselves to specialists in this or that branch of technical chemistry. It differs from books of a similar tendency chiefly in this, that it is not a mere compilation, but essentially an original production. We need not go into the general details of the book, but may mention a few samples of its contents. After a series of useful mathematical tables, subjects specially chemical in their nature are taken up, such as correction of weighings, reduction of specific gravities, calibration, gasometry, gas analysis, gas absorption, and thermometry, and under each of those headings Professor Dittmar shows his originality. When the second part has appeared the book will be most valuable for reference to chemists and others, and we have much pleasure in commending it to the attention of our readers who are interested in the subjects the book embraces.

MAP STUDIES OF THE MERCANTILE WORLD. By John Yeats, LL.D., &c. London: GEORGE PHILIP & SON. 1890.

The author of this book, Dr. John Yeats, was for twelve years Examiner in Commercial Geography and History to the Society of Arts, and has written many books on the subject, which are recognised as valuable to the student and the merchant. The one before us is intended to show how maps should be read, and the information which should be given in connection with them with regard especially to commerce and industry. It is, in fact, a treatise on commercial geography, arranged in a somewhat informal manner, but not on that account, any less useful. It attempts to answer for all the chief countries of the world questions which should be understood by those who have commercial dealings with them. It shows, for example, how the capitals of the various countries are best reached, and refers not only to established mail routes, but also to competing lines for goods and passengers; it gives the industrial characteristics of the people, the chief natural resources of the country, the distribution of raw materials, the direction of the employments towards agriculture, mining, manufacturing, or maritime pursuits. The chief physical features of the different countries are also referred to, especially those which are of importance in commerce, such as inlets and outlets, ports, harbours, and rivers, while a considerable amount of information is given regarding the chief sites of industry and its distributing centres, and the means of internal communication by steam, canal, road, or railway. Of course the great variety of subjects taken up prevent any of them being dealt with exhaustively, but on each there is at least sufficient said to suggest the main points requiring investigation on the part of the student or extension on the part of the teacher. The author dwells on the competition and rivalry which has sprung up in recent years in the nations around us, and says that, in order to keep pre-eminent, our work and workers must continue the best. For them to continue the best they must advance; to stand still is relatively to go back, for all our rivals, especially America, Germany, France, the Low Countries, and even the small state of Denmark, are endowing their youthful communities with the principles of industrial and commercial science. The same spirit of enterprise which has placed us in the van of commercial nations will not yield, for want of effort, in the competition of the world, and the author offers his manual as a contribution of commercial facts and principles, which, within convenient compass, furnishes information bearing upon and applicable to the business of industrial, commercial, and social life.

THE GOLDEN GATES OF TRADE. By John Yeats, LL.D., &c. London: GEORGE PHILIP & SON. 1890.

This may be considered a complementary volume to the one noticed above, and therefore we need not enter into many details regarding it. It is intended to be introductory to a study of mercantile economy and the science of commerce, and contains much useful information in easy language. After an enumeration of the necessaries, conveniences, comforts, and luxuries of life, an account is given of the sources of supply, of the effects of division of labour, the nature of rural occupations, town pursuits, markets, and trade centres. The method of conducting business in large cities is sketched, and the chief features of internal and external trade, with its ebb and flow. Competition and co-operation is discussed, and the advantages and disadvantages connected with them pointed out. Then follows an outline of our great oceanic communications, our railway thoroughfares and trade junctions, and the facilities for importing and exporting.

There is a special chapter on a student's requirements for business which ought to be read with attention, as giving some idea of the demands of modern commerce. Note should be taken of the remarks about the necessity for consulting the tastes and wants of our customers, and of more attention being paid to the reports of Consuls and others which contain information regarding these. The remainder of the book is taken up with interesting information, chiefly on subjects connected with physical geography, and studies of the United Kingdom, of Europe, or Asia, Africa, America, and Australia, bearing on trade divisions and commercial resources.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.*

(*Concluded from page* 115.)

Phosphorescence in High Vacua.—I have already pointed out that the molecular motions rendered visible in a vacuum tube are not the motions of molecules under ordinary condition, but are compounded of these ordinary or kinetic motions, and the extra motion due to the electrical impetus.

Experiments show that in such tubes a few molecules may traverse more than a hundred times the *mean* free path, with a correspondingly increased velocity, until they are arrested by collisions. Indeed, the molecular free path may vary in one and the same tube, and at one and the same degree of exhaustion.

Very many bodies, such as ruby, diamond, emerald, alumina, yttria, samaria, and a large class of earthy oxides and sulphides, phosphoresce in vacuum tubes when placed in the path of the stream of electrified molecules proceeding from the negative pole. The composition of the gaseous residue present does not affect phosphorescence; thus, the earth yttria phosphoresces well in the residual vacua of atmospheric air, of oxygen, nitrogen, carbonic anhydride, hydrogen, iodine, sulphur, and mercury.

With yttria in a vacuum tube, the point of maximum phosphorescence, as I have already pointed out, lies on the margin of the dark space.

Bodies will phosphoresce in actual contact with the negative pole. This is only a temporary phenomenon, and ceases entirely when the exhaustion is pushed to a very high point. A U-tube, shown in Fig. 12, has a flat aluminium pole, in the form of a

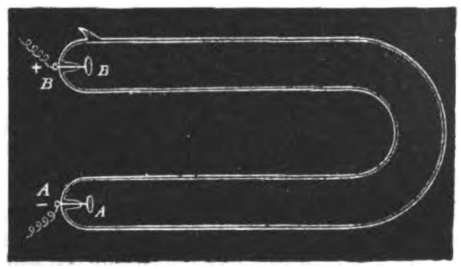

Fig. 12.

disc, at each end, both coated with a paint of phosphorescent yttria. As the rarefaction approaches about 0·5 mm. the surface of the negative pole A becomes faintly phosphorescent. On continuing the exhaustion this luminosity rapidly diminishes, not only in intensity, but in extent, contracting more and more from the edge of the disc until ultimately it is visible only as a bright spot in the centre. This fact does not support a recent theory that as the exhaustion gets higher the discharge leaves the centre of the pole, and takes place only between the edge and the walls of the tube.

If the exhaustion is further pushed, then, at the point where the surface of the negative pole ceases to be luminous, the material on the positive pole B commences to phosphoresce, increasing in intensity until the tube refuses to conduct, its greatest brilliancy being just short of this degree of exhaustion. The probable explanation is that the vagrant molecules I introduce in the next experiment, happening to come within the sphere of influence of the positive pole, rush violently to it and excite phosphorescence in the yttria, whilst losing their negative charge.

Loose and Erratic Molecules.—A C B (Fig. 13) is a U-shaped tube with terminals A and B at each end; D and E are two mica screens covered with a phosphorescent powder,

P = 0·076 mm.

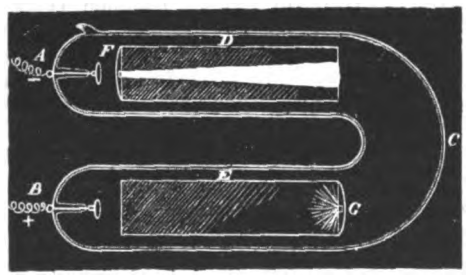

Fig. 13.—P = 0·000076 mm.

having at F and G other screens with a small slit in front, so as to allow only a narrow beam of charged molecules to pass through. At first the tube is exhausted to a pressure of 0·076 mm., or 100 M., and you see how sharp and slightly divergent is the luminous image on screen D, whilst not a trace of phosphorescence is to be seen on the screen E in the other limb of the tube. Now I push the exhaustion to the highest point short of non-conduction (0·000076 mm., or 0·1 M.), and the phenomena change. The initial line of light on D becomes wider and unsteady, whilst at the gate G a decided phosphorescence is observable entering the second screen E. This luminosity diverges to a considerable extent, much more than did the stream of charged molecules observed in the first limb of the tube at the lower exhaustion. This is only to be expected, inasmuch as those sparse molecules which have run the gauntlet of the crowd and have been hunted and buffeted round the corner will have little or no lateral support, but wander to the furthest part of the tube, and altogether behave differently to the orderly procession of molecules at more moderate exhaustion.

The Resistance of High Vacua.—The passage of an induction current at a high vacuum through a tube depends much upon the material of the tube or the substance enclosed within it. Given the same degree of exhaustion and the same distance between the terminals inside the tube, the e.m.f. necessary to force the current through may vary from 8,000 to 20,000 volts, according to the particular material used.

Fig. 14 is a double tube joined by a narrow open channel, and therefore in the same state of exhaustion throughout (P = 0·02 mm., or 26 M.). Each tube is furnished with a pair of poles A B and A^1 B^1. One tube contains the phosphorescent

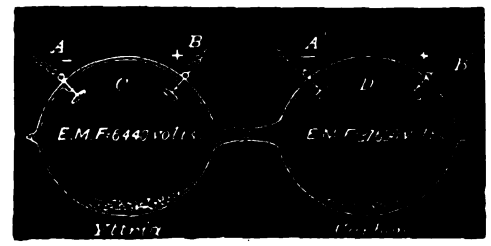

Fig. 14.—P = 0·02 mm.

earth yttria, the other contains finely divided carbon. I first connect the yttria tube C to the coil, and place in parallel circuit with it a spark gauge. To begin with, this gauge is set to a gap of 1 mm. (An e.m.f. of 920 volts is necessary to strike across 1 mm. of air; therefore the difference of potential at the terminals inside the yttria tube is 920 volts, and this you perceive is not sufficient to force the current through the tube.) I now gradually open the gauge until the potential of the inner terminals has risen to a point high enough to allow the spark to pass through the tube, making the yttria phosphorescent.

The gap is at 7 mm. equal to an e.m.f. of 6,440 volts. I next attach the coil wires to the tube D, containing the carbon, and the exhaustion in the tubes being the same as before, I repeat the experiment. You now see that the gap has to be opened to 30 mm., equivalent to an e.m.f. of 27,600 volts, before the current will pass through the tube. The fact of whether the vacuum tube contains yttria or carbon makes a difference of 21,160 volts in the e.m.f. required to cause a discharge between the terminals.

What Occasions Phosphorescence?—So far I have found this phosphorescence to be an attribute of non-conductors only. We know that in the act of phosphorescence the molecules of yttria are in a state of intense vibration. Each molecule may be viewed as the radiating centre of the entire bundle of rays, which, when decomposed by the prism, displays a discontinuous spectrum. We may also suppose that the residual atoms of gas charged with negative electricity give off their electricity on coming in collision with a phosphorescent body, and on their return take up a fresh charge.

The Electrolysis Hypothesis.—There is a certain amount of evidence in favour of an electrolytic hypothesis of the passage of electricity through rarefied gases.

A molecule of hydrogen gas, for instance, may be made up of one group of atoms of hydrogen having an equivalent of negative electricity inherent in it, and one group of atoms having an equivalent of positive electricity bound up with it. These atoms are also charged with *additional* equivalents of positive or negative electricity, which they carry about as a ship carries its cargo. We are not concerned with the inherent electricity—of which we are ignorant—but with the extra or "cargo" charge. Let us imagine a molecule of hydrogen near the face of the negative pole in a vacuum tube. I turn on the current, and the atoms of the hydrogen molecule are dragged apart. The positive atom is attracted to the negative pole, where the violence of impact, or the discharge of electricity, renders it apparent with evolution of light. The internal luminous layer, which is closely adjacent to the negative electrode, is due, therefore, to the positive atoms rushing to the negative pole, and not, like the glow round the edge of the dark space, to the negative atoms projected from it. The negative atom, on the other hand, is driven violently from the negative pole, in virtue of the mutual repulsion existing between any two bodies similarly electrified, with a velocity varying with the intensity of the electrification and the degree of the vacuum; the more perfect the vacuum the greater the velocity, the atoms flying outwards in straight lines until they meet with an obstacle. Such an obstacle may be a procession of positively charged atoms from the positive pole. In this case the two kinds of atoms mutually discharge each other's cargoes with a display of light. This phenomenon occurs at the margin of the dark space when the vacuum is only moderate; or the obstacle may be produced by the vacuum being so high that the atoms of gas present are too few to form a continuous procession.

The Dark Space in Mercury Vapour.—In applying the electrolytic hypothesis, I have used for illustration's sake the gaseous residue of hydrogen, which is known as a diatomic gas. I have found, however, the phenomena of the dark space, &c., to occur

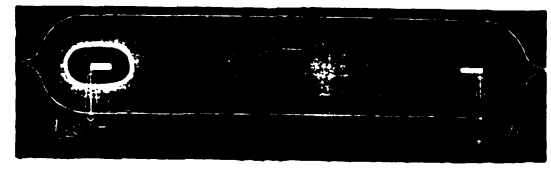

Fig. 15.

in the vapour of mercury, which is a monatomic gas. This important result induced me to patiently investigate this subject, and the result of one experiment is before you (Fig. 15). The tube is furnished with aluminium terminals, and is so arranged that the induction spark can be kept passing during exhaustion to drive off occluded gases. When at the highest attainable vacuum, the tube is filled with pure mercury by simply raising a reservoir. On applying heat the entire contents of the tube are boiled away and pass down the fall tubes of the pump, exhaustion going on at the same time. When the whole of the mercury has thus been boiled away *in vacuo*, except a little condensed at the upper part of the tube, the results on passing the spark are as follows:—When the tube is cold the induction current refuses to pass; on gently heating with a gas-burner the current passes and the dark space is distinctly visible. Continuing the heat so as to volatilise the drops of mercury condensed on the sides, the whole tube becomes filled with a green phosphorescent light, the dark space gets smaller and smaller, and ultimately the negative pole becomes covered with a luminous glow. On allowing the tube to cool the same phenomena ensue in inverse order. The luminous halo expands, showing the dark space between it and the pole, and this dark space gradually grows larger as the tube becomes cooler. The mercury again condenses on the side of the tube, the green phosphorescence grows paler and paler, until at last the induction spark from the large coil refuses to pass.

At first sight this result appears fatal to the electrolytic hypothesis, for if the molecule of mercury contains only one atom how can we talk of its separation into positive and negative atoms by the electric stress? It must be remembered, however, that we are as yet ignorant of the absolute mass of the atom of any element. All that can be said is that a molecule of free hydrogen becomes halved in combining chemically with certain other elements, whilst a molecule of free mercury does not suffer division on yielding any known compound of mercury; the physical atoms in the one behave as two separate groups, and those in the other as one undivided group.

THE HERMITE ELECTRO-BLEACHING PROCESS.

We have on previous occasions given our readers details of the progress made in the process of electrolytic bleaching, and herewith we illustrate the plant which is now at work at the wood-pulp works of MM. Darblay, in the Tyrol, for which we are indebted to the *Revue Internationale de l'Electricité*. It will be recollected that the bleaching liquid is obtained by the electrolysis of a solution of magnesium or calcium chloride. In Fig. 1 we show the electrolyser employed at the above works. It consists of a galvanised iron bath, through which

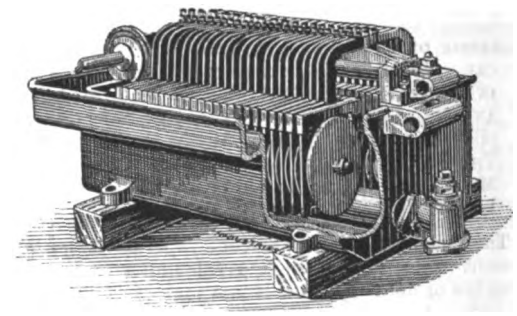

Fig. 1.

there passes a perforated tube. The solution of magnesium chloride is introduced into the bath by this tube, and the liquid, as it fills the tank, overflows into a channel which is connected with a pipe, not shown in the illustration. A continuous circulation of the liquid is thus ensured during the electrolysis. The negative electrodes consist of discs of zinc mounted on a frame which slowly rotates, and between each pair are fixed sheets of platinum, fastened on to ebonite supports, which form the positive electrodes. The several pieces of platinum are carefully soldered to strips of lead, which in their turn are connected by binding screws to a bar of copper which runs along the whole length of the vessel to the positive pole of the dynamo. One of the positive electrodes is shown in Fig. 2. The negative electrodes are in metallic connection with the tank itself, which is connected with the negative pole of the dynamo.

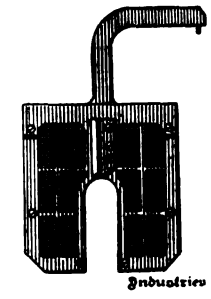

Fig. 2.

In order to keep the negative electrodes in their proper position, the positive electrodes are furnished with flexible ebonite rods, which press against the rotating zinc discs, so that their surface is kept clean and bright. The

* Abstract of Presidential Address given by Mr. William Crookes, F.R.S., before the Institution of Electrical Engineers on the 15th ult.

Digitized by Google

apparatus works well and requires little attention; every few weeks the tank is emptied through a door at the bottom, and thoroughly cleaned by means of a powerful jet of water. There is little wear on the electrodes, and the dynamos employed, although specially constructed for the process by Messrs. Paterson & Cooper, do not differ in any essential details from ordinary types. The current employed is from 1,000 to 1,200 amperes, and when several electrolysers are employed they are connected in series. Each electrolyser in 24 hours produces a bleaching liquid which has the efficiency of 100 kilos. of bleaching powder, with a current of 1,000 amperes at a pressure equal to 6–7 volts. In Fig. 3 a sectional elevation of the works is shown, in which A is the tank containing the solution to be electrolysed, B B the electrolysers, and C the dynamo. D is a wooden conduit by which the electrolysed liquor is led to the bleaching vats E, and from thence transferred to the tank G after the bleaching has been effected. The spent liquors in G and those removed from the bleached pulp by the filter press V are returned to the vat A by the pumps K and H respectively.

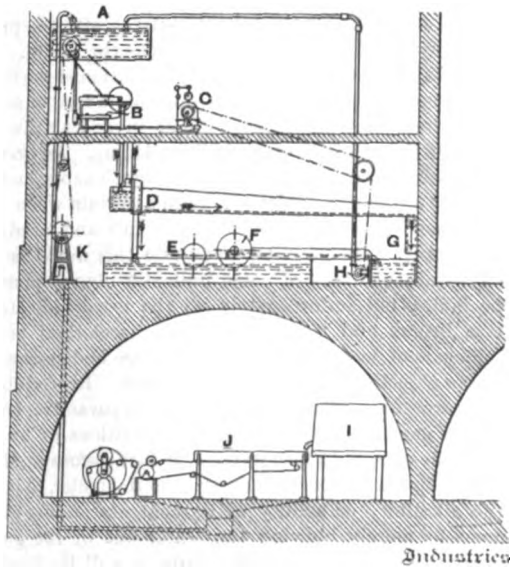

Fig. 3.

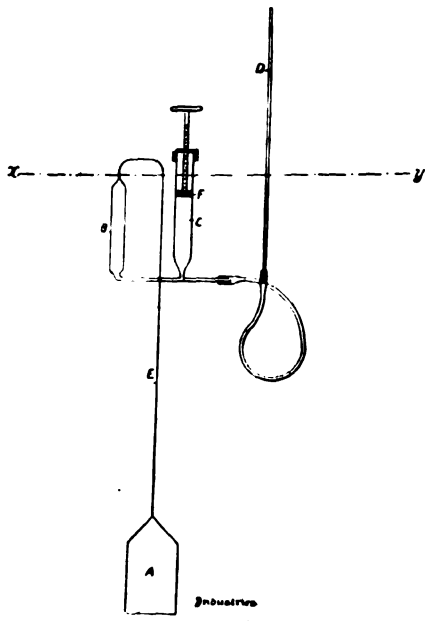
In England we regret to report that the experiment with this plant at the Ely Paper Works, Cardiff, has proved unsuccessful. It is to be hoped that further capital will be forthcoming, so that the difficulties met with in England may be successfully overcome.

ANALYSTS' QUALIFICATIONS.

Some important remarks were made by Mr. Adams, the late President of the Society of Public Analysts, at the meeting recently held by that body. It is the custom in most societies of the kind to encourage their retiring leaders to indulge in mild lucubrations on things in general in a conciliatory spirit. But on this occasion there was a specimen given of straight talking. In the first place the present system of appointing public analysts, astouched upon by Mr. Adams, claims consideration. It is notoriously true that the motives inducing the appointment of some candidates are far from single. Naturally in most districts a considerable proportion of the men constituting the local governing body in whom the appointment rests are interested in factories and shops concerned in the production and distribution of those materials which it is the business of the public analyst to examine, and upon which he has afterwards to pronounce an opinion. This being so there is a direct incentive to those who are conscious that their wares will ill bear scrutiny to endeavour to secure a lenient judge. We may feel certain that the fraternity of theft would appreciate the value of controlling the appointment of police officers, but it is not customary to consult the brotherhood in this matter. Similarly it is distinctly desirable that persons profiting by the variety of fraud known as adulteration should have no voice in the appointment of the functionary whose business it is to check that nefarious practice. The suggestion may here be made that it would be well, from the point of view of expediency, to enact that persons convicted under the operation of the Sale of Food and Drugs Act should be thereby incapacitated from holding any office in the local governing bodies concerned in the appointment of public analysts. Pending some such provision, a close watch should be kept on the character of the successful candidate, on those of the members of the appointing body, and on the relations that may exist between them. Since all appointments of the kind have to be approved by the Local Government Board, the rejection of an unqualified or unsuitable appointee can be secured by making the necessary appeal to that body.



A second and equally important matter claiming attention is the practical question of the best method of electing a qualified man for the post of public analyst. At present there is absolutely no qualification specially designed for the purpose. Fellowship in the Institute of Chemistry is, or is supposed to be, a guarantee of general analytical competence, but the work of the public analyst is of a more specialised character, and those performing it should hold a corresponding diploma. We do not mean to assert that the duties of a public analyst need for their proper execution a higher training than is necessary for a good works chemist. Still less would this be true if comparison were made with the course of study and subsequent experience through which those occupying the higher grades of the profession must have successfully passed. As a matter of fact, the qualification necessary for a trustworthy public analyst is not difficult of attainment by any honest worker trained aright.

Passing to the consideration of the actual means to be employed in conferring a diploma that shall be a guarantee of competence on those seeking posts as public analysts, one is confronted by the inevitable examination question. It is clearly evident that no system of examination can pick out the best men of any profession, because the quality that ranks them as best—viz., original power—can be measured by no examinational standard. But a reasonable degree of competence without any particular originality suffices to ensure the proper discharge of the duties of a public analyst, and this can be secured by a *wisely devised* method of examination. The adoption of a plan similar to that already in force for the selection of officers having an adequate knowledge of hygiene would be perfectly feasible, and lead to satisfactory results. It remains a question whether the Society of Public Analysts might not itself assume an examinational function, and confer a diploma valuable as a testimony to the possessor's fitness for the post of public analyst. That can be decided by the Council, and, without wishing to dictate to it in any way, we commend it to its immediate and earnest consideration.

A third subject remains to be dealt with. About this time last year overtures were made by the Institute of Chemistry to the Society of Public Analysts to induce the latter body to throw in its lot with the former. As Mr. Adams reminded his auditors, there was a considerable section of the smaller society willing to listen to those overtures, and doubt was felt whether another year would see the Society of Public Analysts still possessed of a separate existence. But the wiser view of those who feared that the definite aims for the attainment of which the Society of Public Analysts was formed would be overlooked were it to be absorbed into the Institute prevailed, and the project is dormant, if not defunct. Considering the large and eminently useful programme now before the Society of Public Analysts, we can heartily endorse its belief in the necessity of retaining its independence for the better accomplishment of those purposes which it has in view.

A NEW FORM OF AIR THERMOMETER FOR TECHNICAL PURPOSES.

Professor A. H. Sabine has devised an air thermometer of simple construction, which should prove of service in varnish factories and for other technical purposes in which it is necessary to heat substances to constant temperatures and through a wide range. He was led to construct the instrument which we illustrate herewith from noticing that a comparison of several ordinary thermometers used for determining the temperature in a varnish factory gave considerable differences in reading under similar circumstances, these differences amounting to as much as 50° F. at a temperature of 500° F. The expansion of mercury is not, as is well known, uniform when we approach its boiling point, and under pressure, as in the nitrogen-filled instruments commonly used, it also probably behaves in an irregular manner. Glass, too, when near its softening point, has probably a different rate of expansion, and thus adds to the error in an uncalibrated instrument. Even when naphthalene and benzophenone are used for fixing two points high on the scale, no uniformity can be assured, and, as a matter of fact, it appears at present with such instruments only possible to put arbitrary marks instead of degrees, and heat up to these marks. Each instrument has, therefore, to be calibrated in this fashion before it can be safely used. The air thermometer proposed, as shown in the sketch, consists of an iron vessel A, containing air, which is connected by means of a long capillary glass tube E to a reservoir B containing mercury. By means of a small pressure pump F the air can be compressed to a constant volume for any desired temperature, a tube D, containing air, and connected with the mercury, serving as a gauge to indicate the mercury pressure required for different pressures. The air

gauge of the instrument should contain a small thermometer, and a sliding scale can be arranged if desired. In the original paper, in the Journal of the American Chemical Society, the author gives details as to the method by which the pressure readings can be converted into degree readings, and shows how corrections can be made so as to allow for the expansion of the iron bulb and any change of temperature in the air of the gauge glass. In the illustration the horizontal dotted line X Y shows the level of the mercury in the capillary tube and gauge glass.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

At a meeting of this Society, on the 2nd inst., Mr. W. Young read a paper on "Normal Sperm Candles," in which he pointed out the conditions under which he had been able to obtain fairly concordant results with the official standard candles. He showed that under the present regulations of the Gas Referees, two gas examiners in the metropolis might obtain very different results with the same gas, and that although the details of manipulation laid down by the Referees were far more minute than formerly, they were not adequate, as shown by the more numerous appeals to the official returns since the new notification had been in force. His experiments tended to show that a candle could only be said to obtain its normal rate of burning after it had been allowed to burn for some time, then blown out, and relit for two or three times. In tables accompanying the paper, the author showed that a standard candle, when first lit and allowed to burn for the time prescribed, gave very different results to a candle which had been relit several times as above described, and he believed—although he had had some experience with the proposed new standards of light—that if candles were used in the way proposed they would be found to possess all the requirements of a practical light standard. The author also pointed out that the standard Argand burner in which the gas was burnt gave different readings with thick and thin glass chimneys, and that slight variations in the colour of the glass employed for the manufacture of these chimneys affected the result.

In the discussion, Mr. W. J. Dibdin pointed out that it was well known that with coaxing and care satisfactory results could be obtained with candles, but that the red tape of officialism prevented the gas examiners from using their common sense and practical experience when carrying out the tests; that so long as candles were the official standard the instructions of the Gas Referees had to be *legally* followed, and that, although the result obtained might be one which the operator in unofficial work would neglect, it would have to be recorded as the official test. He thought that the work which Mr. Young had done in this direction was of the greatest value, as showing the variation in the present standard of light.

Digitized by Google

Mr. Foster suggested that a candle might be constructed with an incombustible wick, and thus overcome many of the difficulties met with in their use.

Dr. Rideal hoped that the time had come when they would cease to discuss what is meant by a standard candle, as the large amount of work which had been devoted to this subject had already proved that there were several species of standard candles. A point of great importance was the variation in the light emitted by a candle when surrounded by a different environment, and he thought that more good would be done by rousing the County Council from their lethargy in this matter, and urging on the Board of Trade to do away with candles of all sorts as a standard of light, than discussing what a bad standard they were.

Dr. C. R. A. Wright pointed out that sperm was a very indefinite substance, and that considerable variation might be expected in candles made from such a material.

Mr. Lacy, speaking from the view of the gas companies, thought that in any attempt at introducing a new standard of light it would be difficult to assign to it a value in terms of the parliamentary candle which would be agreeable to all parties.

Mr. Young then replied at some length to the points raised by the various speakers, and at the close of the meeting Mr. J. Brown exhibited the "orthophote," a slide rule arrangement for facilitating the calculation of the correct illuminating power from the photometer readings.

Notes.

NEW ZEALAND RAILWAYS.

From an official statement issued by the New Zealand Government, we find that in March last there were in that colony 684 miles of railway in the north, and 1,129 miles in the south island, and that during the year there were 43 miles opened. The average cost per mile has been £7,750. The average cost in Britain has been £37,800 per mile, or nearly five times as much. The best paying line shows a profit of about 5¼ per cent.

UNIFORM COLONIAL PENNY POSTAGE.

We recently stated in our columns the modifications which had been made in the rate of colonial postage, which had been reduced to 2½d. We understand, however, that Mr. Henniker Heaton's proposal for a uniform penny postage with all our colonies is being carefully considered by the Chancellor of the Exchequer, and that there is a strong probability of his finding the necessary funds for carrying it out from the expected surplus in the next Budget. The change, we believe, would only involve an initial loss to the revenue of £20,000 a year, and it is expected that this amount would soon be more than recouped by the great increase in the amount of correspondence carried.

COAL IN INDIA.

We recently directed attention to the competition Lancashire was likely soon to have with India. In the production of coal also it almost looks as if India may become a rather serious rival. Last year for all India the production was 2,045,359 tons, of which Bengal furnished 1,641,354 tons, the Central Provinces 144,465, Assam 116,676, and the Nizam's territory 59,646 tons. In 1880 the total production was 1,019,793 tons, so that in ten years it has practically doubled. At the commencement of that period the only fields worked were those of Bengal and the Central Provinces; at the end there were mines in addition in four other provinces and territories. In Bengal the yield increased from 988,565 tons to 1,641,354, and in the Central Provinces it increased nearly five-fold.

NEW LOCOMOTIVES FOR THE NEW SOUTH WALES RAILWAYS.

According to the *New South Wales Railway and Tramway Review* orders have lately been given out for no less than 130 new engines for the New South Wales railways. Our contemporary remarks:—"This is taking the bull by the horns with a vengeance, considering that we have wasted several years in deciding what shall be done, and that prices are now very high. The English makers will supply about 118, at a cost of £3,650 each. America will build twelve more, at a cost of £3,557 each, so we are told by the Minister. As we cannot get to know here on the spot just what kind of engine we are to have, we have gone abroad for the information. The *Railroad Gazette* (N.Y.) of 6th June states:—'The Government of New South Wales has accepted an offer of an English and Colonial syndicate to establish locomotive building works in the colony. Three standard types of locomotives will be built, one for main line traffic, capable of hauling either freight or passenger trains over the ruling grades of 132ft. per mile. These engines will be six-coupled, inside-connected, tender engines.' Another type will be tank engines for suburban passenger traffic, with four-coupled wheels and four-wheeled truck under leading end; while the third type, for local coal traffic and switching, will be also tank engines, but with six-coupled wheels and a rear truck. Mr. D. Drummond was to superintend all this, but we have lately seen that that gentleman has given up a good appointment on the Caledonian Railway for a 'castle in the air,' the whole business being now abandoned and orders given out as explained above."

SOLDERING METALS TO GLASS OR PORCELAIN.

M. Cailletet has devised a simple method for connecting glass tubes to metal work in the construction of physical apparatus, which may be of service to our readers. The end of the glass tube is first gently warmed, and then covered with a few drops of a solution of neutral platinum chloride and camomile oil. On gently warming the tube to a dull redness the platinum salt is reduced to the metallic state, and a brilliant deposit of the metal is formed on the end of the tube. The tube is then connected to the negative electrode of a battery and immersed in a bath of copper sulphate, when the copper is deposited as a malleable adherent coating on the platinum flux, and thus forms a material which can be brazed on to brass or copper in the ordinary way.

A NEW SOAP FOR METAL WORK.

The soaps used for cleaning metal work usually consist of mixtures of vaseline, oleic acid, and fat, mixed with a small quantity of rouge. When freshly prepared they leave nothing to be desired; but, unfortunately, such mixtures soon turn rancid and become unfit for use. A new soap for metal work, which is stated to be free from this objection, is made from cocoanut butter in the following way:—2·5 kilos of the butter is melted in an iron vessel, together with a little water, and to the mixture is added, with constant stirring, 180 grms. of chalk, 87·5 grms. of alum, 87·5 grms. of cream of tartar, and 87·5 grms. of white lead. This mixture is then poured into moulds and allowed to solidify. The soap so obtained is made into a paste with water and rubbed over the metal to be cleaned, and finally removed by a dry rag or chamois leather,

A BATTERY TRANSFORMER.

Professors Rowland and Duncan, of Baltimore, have designed a commutator arrangement for connecting up batteries in series and parallel, so that they are rapidly charged and discharged. For instance, if the transmitting pressure is 1,000 volts and the distributing pressure 100 volts, one battery is divided into ten parts. These are connected to twenty brushes, and the charging and distributing circuits have two more brushes each. The commutator has strips so arranged that for nearly half a revolution the cells are charging in series, and for nearly half a revolution discharging in parallel. In the intermediate interval they are disconnected. To keep both charging and discharging currents continuous two or three batteries are used. This arrangement would, no doubt, work, but we question whether it is practical. The commutator is a little complicated, and forty-eight brushes do not commend themselves to engineers. Certainly the commutator could be arranged to work with twenty-four brushes, but even that number is rather prohibitive.

FRANKFORT ELECTRICAL EXHIBITION.

A large number of officials of the Imperial Post Office of Berlin, representatives of the Prussian railways, and delegates of the postal and telegraph service of Wurtemberg met on the 24th ult. at the Oërlikon Works, where some highly interesting experiments were made in producing and transmitting high-pressure electrical currents. The experiments were made in order to furnish the delegates of the Imperial German Government with proof that such high-pressure currents can be transmitted to great distances without danger of accidents or loss of power. The party of visitors were busy all day in examining the various appliances and their working, and it was evident that they were well satisfied with what they saw. It has been arranged to transmit a power of about 300 h.p. from Laufen-on-the-Neckar to Frankfort, for the Electrical Exhibition which is to be opened there on the 15th of May next, and this will be effected by means of high-pressure currents, carried by conductors, which are to run by the side of the rails, telegraph, and telephone wires of the State Railway line. At Oërlikon the experiments were made on an open air wire about seven kilometres long. The electricity, after having been transformed from a pressure of only 100 volts into a pressure of about 30,000 volts, was sent through the wire at this enormous pressure without any danger, and with little loss of power.

AN INDICATOR OF ACIDITY IN BOILER WATERS.

As is well known, water containing magnesium chloride is injurious to boilers, as the salt dissociates with the production of hydrochloric acid which attacks the plates. In large installations, where systematic purification of the feed water can be adopted, this evil is prevented, but in most cases the treatment in vogue consists in adding caustic soda to keep the contents of the boiler alkaline. An excess of the soda is wasteful and otherwise objectionable, and it becomes desirable to be able readily to ascertain when the water in the boiler ceases to contain alkali and needs a further supply. The handiest way to do this would be to have a certain quantity of some indicator always present in the boiler, but unfortunately all the usual indicators, such as litmus and turmeric, become decolorised under the influence of water at high temperature and pressure; the same objection applies to Congo red. Dr. Goldberg has, however, found that the sodium salt of paranitrophenol is entirely unaffected either by these conditions or by the salts usually present in feed waters. It is therefore possible, by introducing a sufficient quantity into the boiler, to judge of the alkalinity or acidity of its contents at any given moment by merely blowing the water out of the gauge glass and allowing it to refill. To give a distinct yellow colour (the evidence of alkalinity) to the water, so that it may be seen in the small quantity of water in the gauge glass, about 30 to 50 grammes per cubic metre are requisite. The high price of the substance is the bar to its general use at present, the cost of the pure material being about 5s. a pound. As its successful application is not dependent upon its purity, a crude variety could doubtless be produced much more cheaply if a demand arose for it.

THE CANADIAN CATTLE TRADE.

In the course of the inquiry that is being held in Canada in connection with the live cattle trade, a good many suggestions have been made for the improvement of the accommodation on board the ships engaged in the trade. The managers of the Marine Insurance Company have been conferring upon the subject, and they have made the following recommendations to the Commission:—That no vessel for live stock should be passed by such an officer as suggested (that is, a Government inspector) unless she is equipped and built as follows:—(1) That there be at least 7ft. 3in. between deeks; (2) that she be provided with steam fans, or fans of sufficient capacity to force fresh air between decks in quantities ample for all the animals placed on said deck or decks. They also recommend that there should be a condenser of sufficient size to provide fresh water for all animals carried. That there should be angle-iron frames fitted side by side on the top deck, 3ft. apart, on all steamers carrying a deck load of cattle, to be fastened in 2in. planks. That steamers should be at least 1,200 tons net register, and have at least 250 horse-power. That there should be a sufficient number of water barrels and hose conveniently placed. That the space to be allowed for each animal should not be less than 2ft. 8in. by 8ft., it being understood that five stockers (not to weigh more than 1,000lb. each) may be allowed in the space for four fat cattle, and that not more than ten sheep be placed in the space allotted to one fat ox. Neither high nor over fed cattle to be carried on deck, but in every case to be stowed under deck in a convenient place. That no head ropes of less than 1in. in diameter be allowed. That all steamers carrying live stock be fitted with the electric light. That in fitting up stalls passages should be left so that the scuppers can be reached and kept clean. That cattle should have at least twelve hours' rest after leaving the car before they are put on board.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

19th January, 1891.

913. Winterton, J. ..... Platen printing machines.
918. Brimelow, P. ..... Reed pocket and mechanism for locking the same in a loose fast reed loom.
920. Dracup & Burrows ..... Doubling and twisting machines.
926. Sellers, J. M..... Screw and stud making machines.
934. Heys, W. ..... Miners' safety lamps.
942. Gedge, W. E. ..... Fluid meters (*Hesse*).
944. Kohler, E. ..... Sewing machines.
945. Lowe, S. ..... Knitting machinery.
949. Swinbourn, J. M..... Ball valve for hydrants, &c.

20th January, 1891.

961. Thompson, W. P. ..... High-speed steam engines (*Pyle*).
968. Sykes, G. D. ..... Apparatus for connecting and adjusting healds in looms.
970. Williams, H. ..... Gas engines.
978. Beardmore, I. ..... Regenerative gas furnaces.
988. Boult, A. J. ..... Punching machines (*Mason, Mason, & Wiegand*).
990. Jeeves & Gilmore ..... Implements for scraping steam boilers and the like.
993. Morison, W. C. ..... Railway brakes.
1003. Ruffles, R. G. ..... Steam boilers.
1006. Thompson, W. P. ..... Paper punches (*The Office Specialty Manufacturing Company*).
1010. Villeroy, E. ..... Crushing machines.
1017. Brosius, S. G. ..... Rotary steam engines.
1020. Birkbeck, H. ..... Machine for making paper tubing (*Greenfield*).
1022. Liley, Holland, & Page Railway signalling apparatus.
1034. Lake, H. H..... Direct-acting steam engines (*Groshon*).
1043. Bonne, C. R. ..... Machine for drying grains, &c.
1044. Wells, C..... Steam engines.
1052. Niclausse & Niclausse Multitubular boilers.

21st January, 1891.

1057. Leeder, F. G. ..... Sand-moulding machines.
1061. Makin, R..... Compound and condensing steam engines for heating, drying, &c.
1072. Williams, P. H..... Thermo-automatic pump.
1075. Harrison, W. ..... Knitting machines.
1077. Frankland, G. H. ..... Pickers for looms.
1081. Stephenson & Stephenson ..... Hay-pressing machinery.
1083. Robinson, H. ..... Gas engines.
1109. Attenborough, E. ..... Condensing engines.
1111. Otto, H. ..... Shuttle-guard tension devices for looms.
1119. Wallis, A. H..... Starting valves for compound engines.

22nd January, 1891.

1159. Newall, G. A. ..... Steam boiler.
1163. Brown, A. F. G. ..... Valve gear for rotary engines.
1164. Brown, A. F. G. ..... Coal-washing machinery.
1165. Brown, A. F. G. ..... Crushing mills.
1169. Lee, W. ..... Steam-lifting pump.
1180. Whittaker, T. ..... Perforated edge runner mills.
1193. Sheldon, J..... Screw rolling dies.
1196. Ross, Sir C. H. A. F. L.... Breechloading firearms.
1206. Jackson & Hoad ..... Pressure gauges.

23rd January, 1891.

1222. Pilkington, W. W. ..... Apparatus for forming molten glass into sheets.
1227. Lees & Lees ..... Steam engine governors.
1228. Whittier, C. ..... Elevator mechanism.
1232. Howard, J..... Railway brakes.
1234. Barber, T. W. ..... Gas engines.
1235. Andrews, G. ..... Lubricator.
1236. Kittner, W. ..... Paper-making machines.
1252. Portbous, A. N..... Rotary engines.
1264. Despret, G. ..... Machinery for grinding and polishing glass.
1265. Woodward, J. ..... Machinery for charging and drawing gas retorts.
1277. De Strens, E..... Steam boiler furnaces.
1282. Capell, G. M..... Centrifugal fans.
1286. Edwards, E. ..... Picking straps of looms (*Held*).

24th January, 1891.

1295. Blakenby, W. H. ..... Pneumatic tube conveying apparatus.
1296. Stewart, D. ..... Sugar cane crushing mills.
1298. Williams, P. H. ..... Locomotives and other motors.
1299. Williams, H. ..... Gas engines.
1306. Scott & Durnford ..... Cut-off valves.
1311. Scott, Hamer, & Carr... Flyers for slubbing, intermediate, roving, and other machines.
1315. Lees & Lees ..... Sawing machines.
1316. Lams, L. ..... Plug valves.
1326. Thompson, C..... Looms.
1328. Munns, W. H..... Car coupling (*McMillen*).
1330. Munns, W. H..... Car coupling (*Marshall*).
1338. Munns, W. H..... Car coupling (*Mohn*).
1348. Penn & Penn ..... Pile-driving machinery.
1369. Horn, W. W. ..... Car couplings (*Blagrave & Marsh*).
1370. Horn, W. W. ..... Box-stapling machines (*Beck*).
1375. Barnes, Sen., & Barnes Car couplings. (26th June, 1890.)

ELECTRICITY.

19th January, 1891.

912. Richards, D. ..... Automatic electric locking gear for railway signals.

20th January, 1891.

980. Walker, Walker, Sansom, & Cole ..... Railway signals.
984. Theiler & Elphinstone Telegraphic transmitting apparatus.
991. Snell, A. T. ..... Percussive rock drill.
1004. Thomson, Sir W. ..... Indicator for electric potentials.
1007. Ferraris, E. ..... Separating ores by electricity.
1035. Maquay, S. W. ..... Primary batteries.
1049. De Ferranti, S. Z. ..... Dynamos.
1050. De Ferranti, S. Z. ..... Electrical distribution.
1051. De Ferranti, S. Z. ..... Transformers.

21st January, 1891.

1066. Burton & Angell ..... Electric blank heaters for forging machines.
1084. Jackson, W. H. ..... Automatic throw-back for electric indicators.
1114. Churchward, A. ..... Electric railways (*Robertson*).
1121. Mayer, E. L. ..... Apparatus for telephonic transmission.
1122. Raine, A. D. ..... Incandescent lamps.

22nd January, 1891.

1173. Thomson, Sir W. ..... Transmission of electric energy.
1176. Newton & Hawkins..... Brush holders for dynamos.

23rd January, 1891.

1251. Atkins & Atkins ..... Switches.
1279. Wiley, Dickey, & Ainsworth ..... Electric railway signals.

24th January, 1891.

1318. Cutler, A. W. ..... Electric distribution.
1332. Munns, W. H. ..... Insulator for electric wires (*Miro*).

CHEMISTRY.

19th January, 1891.

914. Billington & Billington, Jun. ..... Production of aluminium.
950. Leigh, H. H. ..... Metallic alloys (*Huesmann*).

20th January, 1891.

962. Kynaston, J. W. ..... Manufacture of sulphate of alumina.
1001. Read Holliday & Sons, Ld., Holliday, & Seidler ..... Preparation of a new colour producing thio-base, and of sulpho acids of the same.
1047. West, W. ..... Treating zinc ores.

21st January, 1891.

1120. Imray, O..... Dyeing on woollens azo colouring matters derived from dioxynaphthalin sulphonic acids with metallic mordants (*Farbwerke vormals Meister, Lucius & Brüning*).

22nd January, 1891.

1154. Gossage & Williamson Manufacture of sulphur from sulphuretted hydrogen.
1168. D'Andria, M. N ..... Manufacture of barium chloride and strontium chloride.
1197. Mactear, J. ..... Treatment of ores for the extraction of precious metal.
1203. Jones, F. J. ..... Manufacture of sulphate of ammonia.

23rd January, 1891.

1224. Hunt, Wilson, & Stewart ..... Colouring matters.
1225. Tatham, H. ..... Treatment of sewage.

24th January, 1891.

1354. Imray, O..... Production of a blue-green and red-violet colouring matter (*Farbwerke vormals Meister, Lucius & Brüning*).
1355. Imray, O..... Production of disazo colouring matters (*Farbwerke vormals Meister, Lucius & Brüning*).

MISCELLANEOUS.

19th January, 1891.

930. Larder & Bagnall ..... Files.
946. Lébédeff, N. ..... Extracting iron or steel from ores.

20th January, 1891.

976. Johnson, S. A. ..... Furnace bars.
987. Mills, B. J. B. ..... Oil cans (*The Rau Manufacturing Company*).

21st January, 1891.

1107. Thompson, W. P. ..... Vices (*Schwendemann & Perrot*).

22nd January, 1891.

1172. Sintzenich, H. H. C. ... Railway chairs.

23rd January, 1891.

1210. Beeley, G. ..... Furnace bars.
1249. Senior, J..... Oil cans.

24th January, 1891.

1336. Munns, W. H. ..... Oil can (*Raleigh*).

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

116. Potts.
948. Thomas Haylor Howard & James Martin Lapping.
1176. William Sinclair & Murdoch Mackay.
1178. William Sinclair & Murdock Mackay.
1451. Clegg.
1714. Adair.
2142. Hood.
2426. Boult (*Bisson & Bal*).
2543. Warnant-Créon.
2571. Leadbetter.
2659. Parsons.
2789. Wilson.
2815. Harris.
2883. Esson.
3028. Reignier.
3045. Brawn.
3118. Billington.
3282. Alexander.
3343. Fletcher, Brown, & Ure.
3408. Bingham.
3506. Pickering.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Cut-off Mechanism for Slide Valves.—*T. Metcalfe, Bradford.*—The invention embraces improvements in the cut-off mechanism of the slide valves of steam and other engines. Fig. 1 in the accompanying illustrations is a section of a valve and cut-off mechanism constructed according to this invention, Fig. 2 being an end view of the valve and cut-off arrangement, Fig. 3 a plan thereof, and Fig. 4 a plan of the valve without the cut-off plate. The slide valve A of an ordinary steam engine with one eccentric and rod, having steam ports A^1 A^1, and exhaust port A^2 is constructed with two projections B B at the back. C is a cut-off plate, the back of which is toothed and

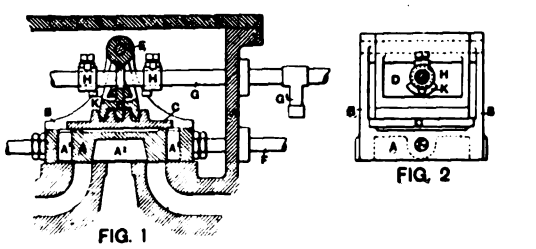

FIG. 1

FIG. 2

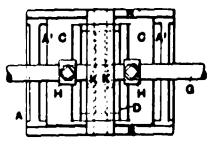

FIG. 3

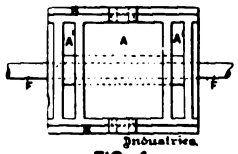

FIG. 4

gears with a toothed segment D pivoted on a pin E attached to the projections B B of the valve A. F is the valve spindle and G a shaft, which receives a circular motion from the governors of the engine through a lever G^1. H H are two stop pieces fixed on to the shaft E by set screws, and K K are inclined projections cast on to the segment D and arranged so as to come into contact with stop pieces H H in the following manner:—The valve A is being drawn, say, from left to right, the cut-off plate C being also carried in the same direction by means of the toothed segment D until the inclined projection on the toothed segment is drawn to, and comes into contact with, the stop piece H on the shaft G, when the horizontal motion with the slide valve A is arrested, and the segment oscillates on the pin E, giving to the cut-off plate C a contrary motion to the valve A, thereby closing the port and cutting off the steam to the cylinder. The inventor also describes a modification of the above arrangement. Claims: (1) In combination with the slide valve of a steam or other motive power engine, a cut-off plate attached to the slide valve by means of a toothed segment or lever, and appliances for changing the horizontal motion of the toothed segment or lever into an oscillating motion, in the manner as shown and described; (2) in combination with the slide valve of a steam or other motive power engine, a cut-off plate attached to the slide valve, and appliances for changing the horizontal motion of the cut-off plate into an oscillating motion substantially as shown and described, and for the purpose set forth.—No. 2329. February 13th, 1890. 6*d*.

Drilling and Punching Machines.—*W. Fortune & F. H. Bentham, both of Bradford.*—This invention relates to machinery for drilling the circles of circular combs used in combing machinery. Referring to the annexed illustrations, Fig. 1 is an end view and Fig. 2 a plan of an automatic arrangement for the above purpose. Upon the slide A on the gantry B is mounted the headstock C. Mounted in bearings in C is a shaft D driven from D^1, and carrying a cam E, which engages projections F F^1 on a horizontal slide G running in guides on the top of C, so imparting a reciprocating motion to the latter. A lever H pivoted at H^1 is connected at one end to the slide I operating the drill spindle J in a second headstock K, and at the opposite end by means of a slot and pin to slide G, so transmitting the reciprocating motion of the slide to the spindle J. To bring the circle into a position for drilling the next hole after one hole has been drilled, a cam face L is formed on E to engage a projection M on an arm M^1 of a lever M^2 pivoted at N in an opening in C. An arm O of this lever is coupled by links to arms P P^1 loosely pivoted on a shaft Q and carrying a pawl R, which pawl engages a ratchet wheel S keyed to shaft Q mounted on C. A spur wheel T, adjustably mounted on shaft Q^1, engages the pinion U mounted upon the standard V, which is the first pinion of motion of the usual mechanism for turning the face plate, and is operated by the handle V^1, the cogs of T being a multiple of those of U, and the teeth of S are equal to the number of times the cogs of T multiply into those of U. When the automatic mechanism is in use for drilling, the pin F is removed, and the slide G moved in the direction to feed the drill by means of a spiral spring W arranged as shown. For punching the holes after drilling, F^1 is replaced so as to reciprocate G in both directions. The ratchet

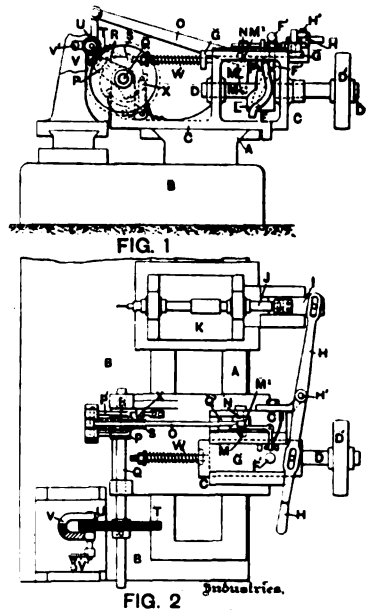

FIG. 1

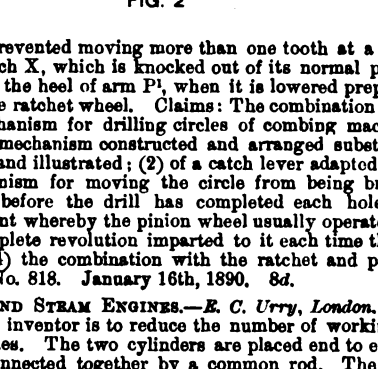

FIG. 2

wheel is prevented moving more than one tooth at a time by a second catch X, which is knocked out of its normal position, as shown, by the heel of arm P^1, when it is lowered preparatory to moving the ratchet wheel. Claims: The combination with automatic mechanism for drilling circles of combing machines—(1) automatic mechanism constructed and arranged substantially as described and illustrated; (2) of a catch lever adapted to prevent the mechanism for moving the circle from being brought into operation before the drill has completed each hole; (3) the arrangement whereby the pinion wheel usually operated by hand has a complete revolution imparted to it each time the circle is moved; (4) the combination with the ratchet and pawl of the stop X.—No. 818. January 16th, 1890. 8*d*.

Compound Steam Engines.—*E. C. Urry, London.*—The object of the inventor is to reduce the number of working parts in such engines. The two cylinders are placed end to end and the pistons connected together by a common rod. The high-pressure cylinder is single-acting, the inner end being always connected with the condenser. The second cylinder is double-acting, the outer side acting as an intermediate cylinder, by means of a hollow trunk fixed or formed on the piston and working in a stuffing-box in the outer end of the cylinder, so reducing the size of that side of the cylinder, and the inner end as a low-pressure cylinder. A valve box is formed on the upper side of the high-pressure cylinder, to the outer end of which is connected the steam supply pipe. Working in this box, and over a port in the outer end of it, leading to the outer end of the high-pressure cylinder, is a piston valve, which alternately allows steam to enter said port to the cylinder and the exhaust to escape by a second pipe. This pipe conducts the steam to the outer part of a double valve box on the second cylinder, a piston valve in which alternately allows steam to enter into and escape from the outer end of the intermediate half of said cylinder, the exhaust therefrom being allowed to escape by a suitable connecting pipe to the inner part of the double valve box, a piston valve working in which allows the steam to alternately enter into and escape from the inner end of the low-pressure half of the second cylinder, the exhaust then being allowed to escape through a suitable port and pipe to the condenser. All three valves are connected together by means of a common rod, and are actuated from the crank shaft of the engine in the usual manner. Claims: The construction and arrangement of compound expansive engines substantially as and for the purpose described.—No. 947. January 18th, 1890. 6*d*.

Tube Flanging Machines.—*E. Heaton, Holt Town, Manchester.*—In the annexed illustrations Fig. 1 is a front elevation, Fig. 2 a side elevation, and Fig. 3 a detail view of the flanging mechanism after the flanging operation. Running in a suitable bearing in the bed-plate A is the face-plate B, having sliding jaws B^1 for holding the boiler tube to be flanged, and driven by means of a gear wheel C on its underside and pinion C^1, as shown. Sliding in a vertical standard D is a carriage E, which can be raised or lowered in the ordinary manner by means of screwed

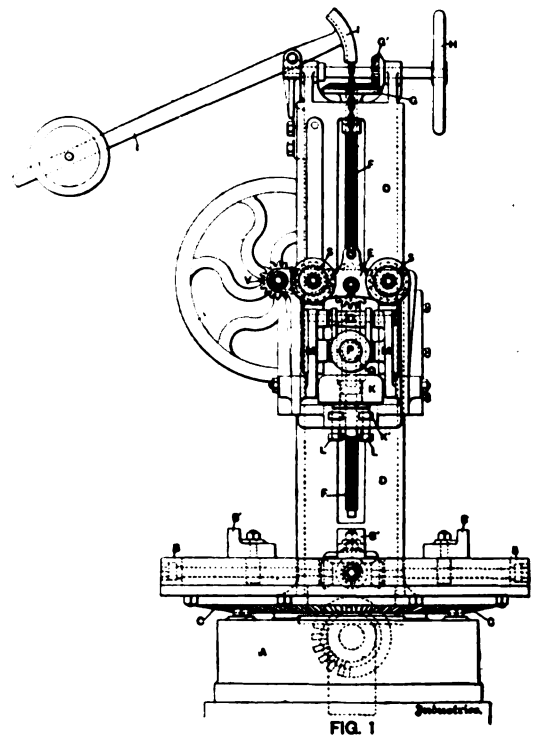

FIG. 1

rod F, passing through an internally screwed nut fitted to slide a short distance in a slide or slot in E, and gear wheels G G^1 and wheel H. In order that E may be raised and lowered quickly and independently of F and its nut, the carriage E is connected to a short arm of a weighted lever I, pivoted at the top of D by a chain, so that, by operating I, the carriage E can be lifted off its nut, which normally supports it. Near the centre of E, mounted upon an adjustable stud J, is a block K, resting on a washer K^1, which can be raised or lowered by set screws L. To the sides of the carriage E is hinged a swinging frame M, consisting of two quadrants N, connected together by a crosshead O, in which is fitted and secured a stud P for the flanging roller Q, so mounted that it can be adjusted relatively to the flanging block K by means of the four screws R. This swinging frame, with the roller Q, is turned about its centre of motion by means of two worms S, which gear into the quadrants; on the shafts carrying these worms are fixed pinions U geared together by an intermediate wheel T, and one of these pinions is driven by another pinion V fixed on the shaft of the hand wheel Y, consequently, when Y is turned in the proper direction both worms S are turned simultaneously, and by means of the quadrants N the swinging frame M is actuated to cause the flanging roller Q to turn the edge of the

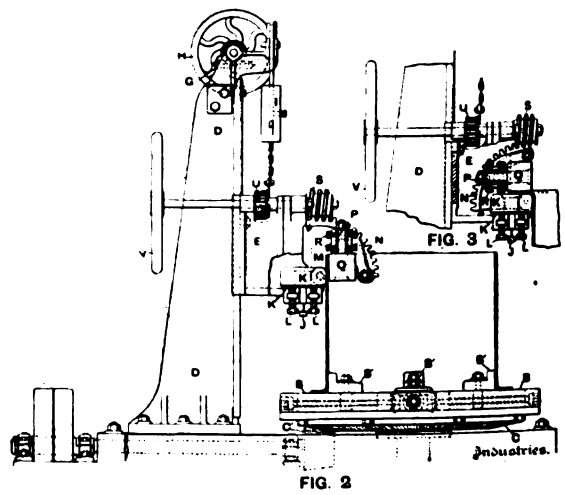

FIG. 2

tube over upon the flanging block K. Claims: (1) Mounting the carriage, which supports the flanging apparatus, so that it can be quickly raised and lowered again independently of the ordinary adjusting mechanism; (2) the combination with the flanging block or roller K of the plate or washer K^1 and the setting screws L; (3) the general combination and arrangement of parts embodying the improvements in flanging machines substantially as described and shown.—No. 16815. October 22nd, 1890. 8*d*.

Thrust Blocks.—*C. S. Snell, Culver Park, Saltash, Cornwall, & B. M. Fletcher, London.*—The object of the invention is to allow the variation in the thrust or pull on the shaft of a screw propeller, or the like, to be utilised to control the amount, direction, or influence of the actuating medium employed. The thrust block proper is mounted in grooves in a suitable fixed plate, in such a manner that it is capable of a slight movement in the direction of the axis of the propeller shaft. Fixed to one end of

Digitized by Google

this sliding block are two arms projecting outwards at right angles to the direction in which the block slides, and fixed on these arms are two plungers working in cylinders fixed on either side of the grooved plate, and the axes of which are parallel to the propeller shaft. One part of each of these cylinders is filled with water, and is so connected by pipes to the governors of the engine actuating the propeller shaft that the more thrust there is the more the water will be compressed, and the governor so actuated to allow steam of a greater pressure to enter the cylinders of the engine, but allows of the reverse action when the thrust is reduced. Four claims are made, embracing the arrangements as described, with modifications to suit other shafts (windmill, turbine, &c.).—No. 15695. October 4th, 1890. 8*d.*

ROCK-DRILLING MACHINE.—*R. Stephens & W. C. Stephens, both of Pool, Cornwall.*—Fig. 1 in the annexed illustrations is a longitudinal section, Figs. 2 and 3 are transverse sections, and Figs. 4, 5, and 6 are details of the valve chest and valve of a rock-drilling

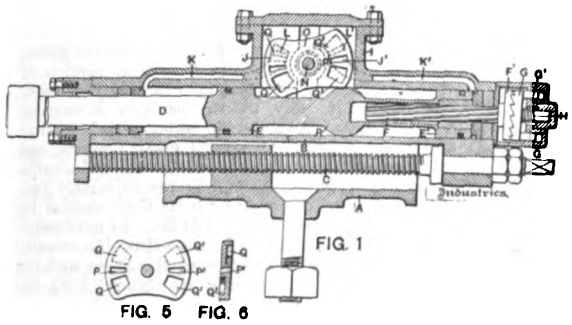

FIG. 1

FIG. 5

FIG. 6

machine embraced by this invention. A is the cradle, and B the cylinder adapted to slide in A by screw C as shown. Working in B is the piston rod D, carrying on its outer end the tool, and having two pistons E E¹. This piston rod is caused to rotate in the ordinary manner by means of the grooved rod F, working in a grooved collar in B, and carrying on its outer end a serrated disc F¹ which engages with a similar disc G prevented from revolving by lugs G¹ and normally held against F¹ by spring H. Fixed to B is the valve-chest I having two ports J J¹ communicating through passages K K¹ to the front and rear of B (Fig. 4), and two exhaust ports L L¹ communicating with the atmosphere, steam being admitted through M. Revolving on a stud N and on the face of I is the valve O (Fig. 5), provided with two ports P P¹, passing entirely through it, and with two pairs of recesses Q Q¹, and being oscillated by means of the protuberance R on D. The ports and recesses in O and ports in I are so arranged that steam will be alternately exhausted from and supplied to each end of the cylinder B, the two positions being shown in Figs. 2 and 3 respectively, the object of the second pair of recesses Q¹ in O being that when one face of O is worn the valve may be reversed. Claims: (1) In rock-drilling machinery the employment of a valve provided with three sets of ports or passages as and for the purpose described; (2) the combination with the twist-bar of two clutch-discs; (3) the combination in a rock drill of a piston, a valve having two sets of ports, one of which passes through the valve, and the other of which is cut out of the body of the valve, the said valve being operated as described, and a twist-bar adapted to be prevented from

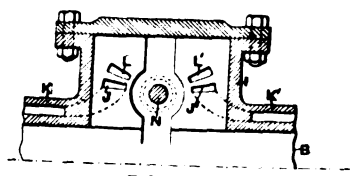

FIG. 4.

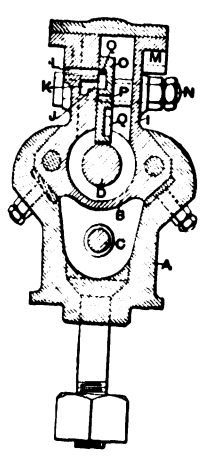

FIG. 2.

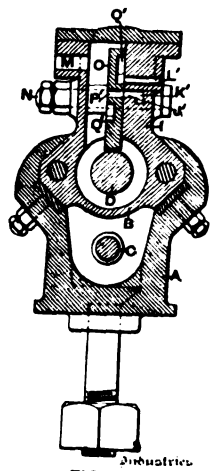

FIG. 3.

rotation in one direction by means of a disc secured thereto, and engaging with a second disc also prevented from revolving, the second disc being adapted to slide upon its axis to allow the disc upon the twist-bar to be rotated during the motion of the piston in the other direction, substantially as described.—No. 2053. February 7th, 1890. 8*d.*

STEAM ENGINE INDICATORS.—*J. D. Davies, Cincinnati, Ohio, U.S.A.*—The invention relates to a device for operating the card drum of any of the well-known indicators, and is constructed as follows:—Fixed on the cross-head of the engine is a stud provided with a sleeve having two projecting arms. In each end of these is fixed a stud, carrying free to revolve a large and small grooved wheel fixed or cast together. Passing over a pulley, at one end of the cross-head slide, is a cord which is then passed over the upper surface of the smaller of the upper pair of wheels on the cross-head, around the under side of the smaller of the two lower wheels, then back over the top small wheel, and continuing its course, passes around a pulley, fixed at the opposite end of the cross-head slide, and returning passes around the two larger wheels of the two pairs on the cross-head, and the two ends are then connected together. From the junction of the two ends of the cord two other cords pass over suitable rollers to the drums of the indicator placed and connected to the opposite ends of the cylinder of the engine. It will thus be seen that supposing the larger wheels on the cross head are 11in. in circumference and the smaller 9in., the stroke being 10in., at each complete stroke the cord will be moved forward through the space of 1in., and so the indicator drums moved correspondingly. Seven claims are made, embracing the arrangement as described, with modifications. —No. 19149. November 25th, 1890. 8*d.*

PERCUSSIVE TOOLS.—*R. Haddan, London.* (*The National Pneumatic Tool Company, New York, U.S.A.*)—In the annexed illustrations Fig. 1 is a longitudinal section along X X of Fig. 3, Fig. 2 a section along Y Y of Fig. 3, and Figs. 3 and 4 cross-sections along lines Z Z and Z Z¹ of Fig. 1 of a percussive tool, worked by fluid pressure and embraced by this invention. The casing A, constructed substantially as shown, has supply and exhaust channels B B¹ (Fig. 2). Within the casing is a piston C having a valve chamber provided with a valve D. The port E communicates with the supply B, port F with exhaust B¹, and port G with the rear end of the cylinder, and port H with the front end thereof. The action of the apparatus is as follows:—When the parts are in the position shown in Fig. 2 in full lines, steam injected through B passes into the valve chamber through E and out through G so as to press against the rear of the cylinder and drive it forward. The steam in front of the cylinder enters the valve chamber through H and passes out through F to the exhaust. When the cylinder has reached the end of its forward stroke, the valve is shifted to the position shown in Fig. 2 in dotted lines. Steam from B then passes through E into valve chamber and out through H so as to press against the forward end of the cylinder and drive C backwards.

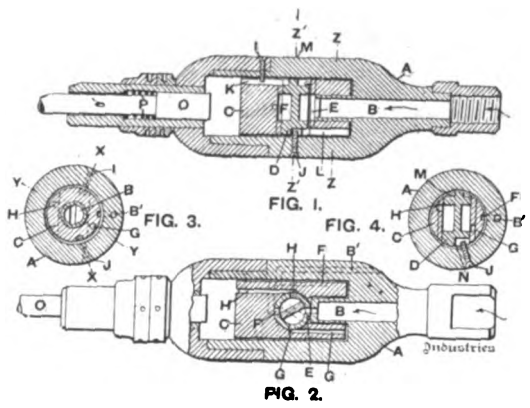

FIG. 1.

FIG. 3.

FIG. 4.

FIG. 2.

The steam in the rear of the piston entering through G into the valve chamber can pass through F to the exhaust. The oscillations of the valve are caused by set screws I J in A projecting into grooves K L in the cylinder. As the cylinder approaches the end of its forward stroke the shoulder M on D comes in contact with I, causing the valve to shift its position, as shown in dotted lines (Fig. 2), the reverse action taking place when the shoulder N strikes J. The forward stroke of piston C causes it to act percussively upon the reciprocating tool-holding rod O, normally held in the position shown by spring P. Five claims are made.—No. 18635. November 18th, 1890. 6*d.*

TOOL HOLDERS.—*W. L. Wise, London.* (*L. Berger, Fils, Thann, Alsace, Germany*).—In a tool holder for machine tools (mortising and like machines) according to this invention the tool is set and fixed at an angle of 60 deg. or thereabouts. The tool is fixed by means of two set screws in a slot formed in a heel on the lower end of the tool holder. The opposite side of this slot to that through which the set screws pass has fitted on to it a plate, the upper surface of which is formed with projections or teeth running across its width. The lower end of the plate is bent around the lower end of the tool holder to prevent it being moved, and is fixed by screws. That side of the tool which is opposite this plate is also toothed across its width, so that the two surfaces fit one another, renderingthe tool practically immovable. Claims: A tool and tool holder for machine tools, in which the tool is held in the holder at a large working angle in relation to the work to be done, is provided with a row of teeth or ridges on the side opposite to the cutting edge, and is pressed by set screws against a lining in the tool holder, this lining being provided with a row of teeth or ridges similar to those on the tool, and with a bent lower end that takes around one edge of the hole in the tool holder, substantially as described.—No. 2890. February 22nd, 1890. 8*d.*

BRICK-MAKING MACHINERY.—*W. Sayer, Derby.*—The object of the invention is to prevent the clay from clogging the knives, cutters, or worms used in brick-making machinery, and to prevent the clay becoming too dense from compression whilst passing through the die. To effect this the "pugging" and expressing knives and worms are made of a rounded or curved section, from where the knife blade joins its boss towards the peripheral tip of said knife, the curved portion receding from the direction of its thrust. To effect the second object, the inside opening of the brick die or mouthpiece of the machine is formed with a projecting cutting edge where it enters into and receives the clay from the expressing or "pug" barrel to which the die is connected by a flange. This allows of the stream of clay being divided from the central column as it is driven or forced up the inside opening of the die, so preventing it being compressed while passing through the latter. Claims: (1) In machines for making bricks and the like, forming the knives, cutters, or worms for "pugging" and expressing the plastic material of a rounded or curved section, as described; (2) in brick-making machines forming on the inner mouth of the dies a cutting edge, as and for the purpose described.—No. 3285. March 1st, 1890. 6*d.*

CUT-OFF VALVE FOR STEAM ENGINES.—*H. W. Morley, Bradford.*—The cut-off valves are arranged as shown in Fig. 1 (a part elevation and part section of an engine cylinder), the actuating mechanism being as shown in Figs. 2 and 3, respectively an elevation and part sectional plan of a steam engine cylinder, together with such parts of an engine necessary to illustrate this invention. The admission and exhaust valves A A at each end of the cylinder B are of the ordinary type, arranged and operated in the usual manner by means of levers C on spindles C¹. These levers are coupled together by the coupling rod D, and are operated by the eccentric E on the main shaft F, through the medium of the connecting rod G, vibrating lever G¹, and connecting rod G². The cylindrical cut-off valves H are mounted between and parallel to the valves A A, within valve chambers I, provided with liners J, for convenience of construction, and

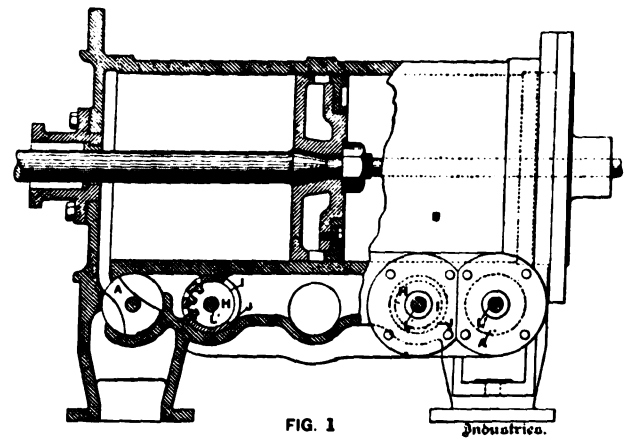

FIG. 1

having "gridiron" shaped ports E¹, to meet the similarly shaped faces of the valves. The valves H are coupled together by the rod K connecting the levers L on the ends of spindles L¹ of the valves, and are opened and closed by a cam M on the cam sleeve M¹ mounted on the shaft N. The shaft N is connected to and driven at the same speed as the main shaft by a pair of bevel wheels O connecting it to the shaft P, driven from the main shaft by the bevel wheels Q. The shaft N is hollow, and receives the end of the governor rod R, which carries the head S free to revolve thereon but confined longitudinally between the collars S¹. This head has a key T projecting through the longitudinal slot T in the shaft N into the helical keyway U in the sleeve M¹. The rod R from the governor is operated longitudinally in the usual manner as the speed of the engine varies, thereby moving the key T in the inclined keyway U advances or retards the cam in relation to the crank shaft or steam piston, and so regulates the cut-off. The cam M operates the slide W by engaging the anti-friction rollers X projecting therefrom, and the slide W is connected to the rod K by the connecting rod Z. Claims: (1) In a steam or other fluid-pressure engine the combination with the admission and exhaust valves of cylindrical cut-off valves, arranged and operated as described; (2) the com-

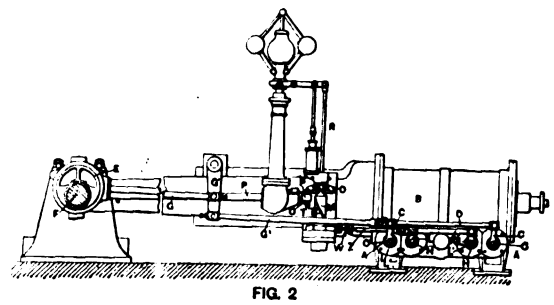

FIG. 2

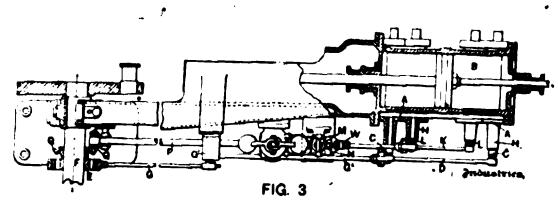

FIG. 3

bination with said cut-off valves of the cam sleeve M with the inclined groove U engaging the key T, arranged to be regulated by the governor, substantially as described.—No. 18318. November 14th, 1890. 8*d.*

TEXTILE MACHINERY.—*J. Haworth, Church Hall, Church, Lancashire.*—The object of the invention is to provide means of thoroughly washing textile fabrics. For this purpose revolving beaters or spurters of a special design are used. These consist of a number of troughs, preferably four, arranged upon radial arms on a centre shaft running in bearings in each side of the washing cistern, the troughs being at the outer end of the arms. The shaft is placed at such a distance from the water that the troughs are completely covered with water when in their lowest position. The outer sides of these troughs have perforations through which, as the troughs open in the same direction as that in which the shaft revolves, the water is caused to flow by centrifugal force. The fabric to be washed is passed around rollers in such a manner that it is brought in contact with the spray or jets issuing from the revolving troughs, which will so wash away any impurity or loose matter in the fabric. Claims: In washing or cleansing machines the use of revolving beaters or spurters arranged in a cistern in such a manner that when revolved they take up water or other liquid and spurt it in small jets with great force against the fabric substantially as set forth; (2) the several combinations and arrangements of parts embodying the improvement in machinery for washing and cleansing textile fabrics, substantially as described.—No. 19367. November 28th, 1890. 6*d.*

Digitized by Google

HYDROCARBON ENGINES.—*J. Dheyne, Schaerbeck, Belgium, & Count de Nydprück & F. de la Hault, both of Brussels, Belgium.*—The invention relates more particularly to engines worked by explosive gases produced by the vaporisation of hydrocarbon and other like liquids. In the annexed illustrations, Fig. 1 is a side elevation of an engine constructed on the principle of this invention, Figs. 2, 3, 4, and 5 being enlarged details thereof. The

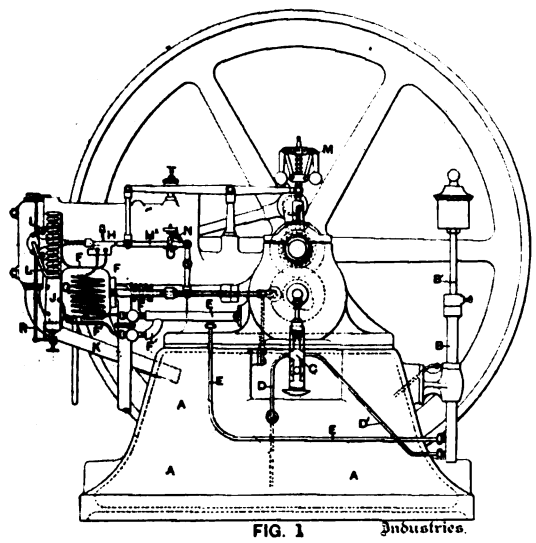

FIG. 1 Industries.

base A of the engine is in the form of a tank and contains the petroleum, which is drawn therefrom and supplied to a vessel B by means of a pump C, actuated from the crank shaft of the engine, through pipes D D¹. From the vessel B, which contains a weighted piston B¹ so as to keep a constant pressure therein, the oil passes through pipe E to two pipes F F¹ provided with stop-cocks. From F the oil passes through a coil (Figs 3 and 4) in the explosion chamber G of the engine, and thence through a slide valve H (Fig. 5) to a coil I, in which it is converted into gas, and the branch F¹ communicates with a coil J where the oil is converted into gas for supplying the flame for heating I and the igniter. From I the gases pass to the engine cylinder, together with air admitted through pipe K, through pipe L, being drawn in by the action of the piston in the usual manner. The valve H, normally kept closed by spring H¹, is reciprocated by push-rod H² and regulated by governor M, as shown, and also further regulated by an adjustable wedge-shaped piece N. The automatic device for regulating the action of the generator is constructed as represented in Fig. 2. The gas generated in the coils J is conducted by the lower end of the coil to a taper orifice O provided with a needle valve P connected to a rod Q, which is automatically regulated by an expansion apparatus consisting of a rod R fixed at its upper extremity S and acting through a lever T centred at U on a nut V, which it moves vertically along with

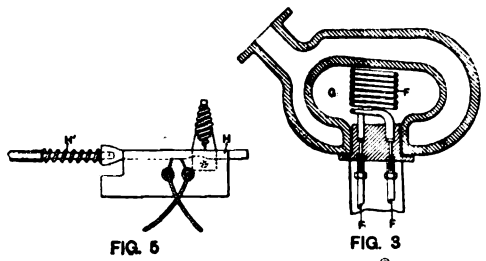

FIG. 5

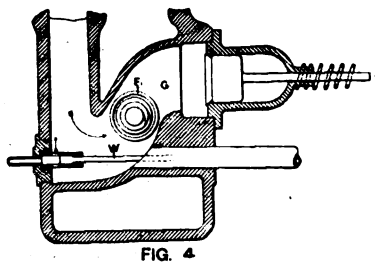
FIG. 3



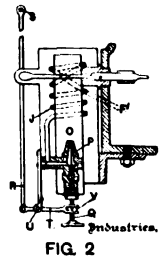


FIG. 4

Industries.

FIG. 2

the rod Q and valve W. The rod R being in proximity to the coil I, Fig. 1, expands when the heat exceeds certain limits in such a manner as to contract or close the orifice O by acting on the lever T, nut V and rod Q. Five claims are made.—No. 5933. April 18th, 1890. 8*d.*

PIPE COUPLINGS.—*C. G. Harrison & H. Howard, both of Halesowen, Worcestershire.*—On each of the ends of the pipes to be coupled the inventors form a flange, standing out at right angles to the peripheral surface of the tube, on the outer edge of which two or more radial arms are formed which extend through an arc of about 30 deg. The radial arms of one of these flanges stand out about twice the distance from the periphery of the flange than those on the other flange. These longer arms are bent over so as to form a clip to receive the shorter arm inside the bent portion. One of the inside bearing surfaces of the bent arms or clips and one of the outside bearing surfaces of the unbent arms are slightly inclined, the inclination following the direction of the curvature of said arms. To unite the ends of the tubes they are placed together so that the bent arms come between the unbent arms. One pipe is then slightly revolved so that the latter enter the former, into which they may be forced by means of a screw clamp, after which they may be fixed by means of screws if desired. Claims: The improvements in connecting metallic pipes as described—viz., forming on one end of the pipe a flange carrying on its outer edge two or more radial arms, one of their faces being preferably inclined, and forming on the end of the other pipe a similar flange carrying on its outer edge two or more clips, one of the bearing faces of which are also inclined, and securely engaging and locking said arms and clips together as described to form a joint.—No. 3719. March 8th, 1890. 8*d.*

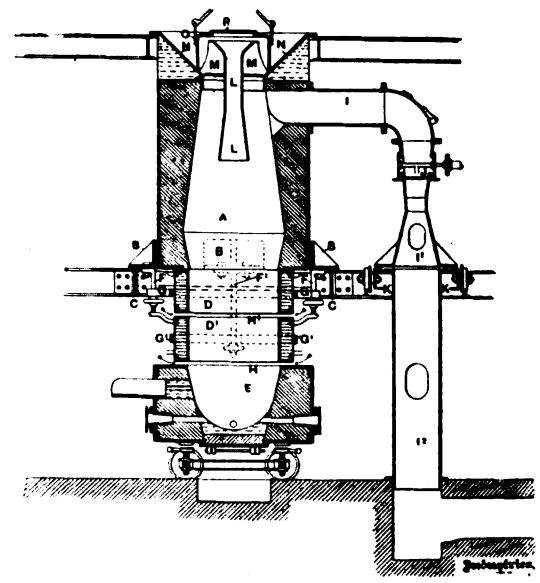
ELECTRICITY.

ELECTROMOTIVES.—*J. Hopkinson, London.*—The invention refers to electromotives in which the dynamo armature or armatures are on the running axles, the object being to construct the armatures of as large a diameter as possible. To effect this the inventor uses a four-pole dynamo machine with the magnets arranged horizontally. Where there are armatures on two adjacent axles, the inventor extends the magnets across from one armature to the other, as well as in front of, and behind, or at the outer sides of the armatures. In this manner power may be applied to the axles of a bogie electromotive. The magnets are suspended from the frame by springs to relieve the weight from the journals by which the axles are connected to the magnets. Claims: In an electromotive the combination of an armature or armatures on the running axle or axles, and four-pole magnets arranged horizontally; (2) in an electromotive the combination of an armature or armatures on the running axle or axles, and four-pole magnets arranged horizontally, and connected together and supported by springs substantially as and for the purpose described.—No. 3732. March 8th, 1890. 6*d.*

INCANDESCENT LAMPS.—*J. W. Edmondson & W. Clarke, both of Gateshead-on-Tyne, Durham.*—For the purpose of cheapening the manufacture of incandescent lamps, of the larger type especially, the inventors, instead of attaching the filaments to platinum wires by a deposit of carbon, by electrotyping, or other ordinary process, connect the carbon rods or filaments with nickel wires or strips that can be attached either directly to platinum or nickel wires passing through the glass of the lamp, or to iron wires or rods that are in turn attached to the platinum or nickel wires above mentioned. The connection between the wires fused into the glass of the lamp and the lamp leads may be effected by means of loops of nickel. For the purpose of fusing the nickel wires into the glass without cracking it the said wires are coated with borax or other suitable flux, or with a thin coating of platinum. Five claims are made, embracing the modification in the construction of incandescent lamps, substantially as described.—No. 20652. December 23rd, 1889. 6*d.*

CHEMISTRY.

MANUFACTURE OF SODA AND POTASH.—*F. Ellershausen, Hebburn-on-Tyne, Northumberland.*—The invention relates to the manufacture of soda by the "Leblanc" process, the object being to effect the removal of the sulphur of the sulphide of sodium, a certain proportion of which is contained in the crude soda. To effect this the inventor uses ferrate of soda, which, when decomposed, the iron combines with the sulphur and precipitates in the form of sulphide of iron, while the soda enters into solution with the soda liquid. In case an excess of ferrate of soda is introduced, it is also decomposed, that portion of the iron not entering into combination with the sulphur precipitating as oxide of iron, while the soda enters into solution with the liquid soda. In the manufacture of potash ferrate of soda is substituted for ferrate of potash. Claims: In the manufacture of soda and potash, treating the crude solutions of the same with their respective ferrates, substantially as described.—No. 1584. January 29th, 1890. 4*d.*



MANUFACTURE OF PAPER.—*E. Applegarth, London.*—The invention refers principally to a method of treating straw, esparto grass, and other fibrous materials, previous to their being used for the manufacture of paper. For this purpose the inventor uses a compound as follows:—15lb. caustic soda, 3 gallons water, 1½ gallons linseed oil, and 5 gallons kerosene oil. These ingredients are well mixed together and boiled until thoroughly combined and reduced to form a more or less firm compound. The straw, esparto grass, or other fibrous material is boiled in caustic lye or other suitable alkaline solution, to which has been added the requisite quantity of the above-described compound, preferably in the proportion of about 1 per cent. of the compound to the quantity of straw or other fibrous material when put into the boiler with alkaline solution (lye). Claims: (1) The improved compound made by mixing together water, caustic soda, kerosene oil, or other unctuous or spirituous hydrocarbon oil or spirit and animal fat or oil or vegetable oil in or about the proportion stated, and subjecting the mixture to heat as described; (2) the treatment of straw or other fibrous material by boiling the same in caustic lye or other alkaline solution in which a suitable quantity of the improved compound is dissolved; (3) straw or other fibrous material treated with the improved compound as described.—No. 2832. February 21st, 1890. 6*d.*

GENERATION OF CHLORINE.—*D. G. Fitzgerald & A. C. Falconer, both of London.*—The invention relates to means for the electrolytic generation of chlorine and compounds of chlorine with earthy bases. For this purpose the inventors employ anodes of peroxide of lead prepared as described in prior patents, No. 4671 of 1885 and No. 16608 of 1886. As electrolytes the inventors employ solutions of any suitable earthy chloride such as chloride of calcium or of magnesium or a solution containing a mixture of earthy chlorides. The anodes are of large surface, and are made by attaching a number of plates of compact coherent and conductive peroxide of lead as above described to a wooden support, the said plates being connected by means of platinum washers and insulated wires to a conductor, preferably of lead, insulated and imbedded in the support. When bleaching, the inventors arrange the anode at the bottom of the tank so as to utilise the free chloride generated and to maintain the anodes in contact with an earthy body. For the cathodes corrugated copper or zinc sheets are used. Claims: In the electrolytic generation of chlorine and compounds of chlorine with earthy bases the use of the aforesaid compact coherent and conductive peroxide of lead or lithanode as an anode in the electrolysis of earthy chlorides substantially as described.—No. 1246. January 23rd, 1890. 4*d.*

MISCELLANEOUS.

WELDING METALS.—*G. H. Cammell, Brookfield Manor, Hathersage, Derbyshire.*—To prevent the oxidisation of the surface of metals when heated for welding, the inventor coats (by electrical deposition or other means) the surfaces of the metals to be welded with nickel or other slowly oxidisable metal. The oxidisation is thus prevented, and the surfaces of the metals become chemically as well as mechanically combined at a welding heat, and different metals (which easily combine with nickel or other slowly oxidisable metal) may be so welded together. The invention is particularly applicable to welding pieces of metal of large surfaces, such as compound armour plates, the surfaces being first cleaned of all oxide, then plated with nickel or other such metal, placed together, heated to a welding heat, and rolled in the ordinary manner. Claims: The welding together of similar or dissimilar metals by the process described, viz., thoroughly cleaning, then nickel-plating the surfaces to be welded, heating the parts to a welding heat, and rolling, pressing, or hammering, substantially as described.—No. 3369. March 3rd, 1890. 4*d.*

SMELTING FURNACES.—*F. A. Herbertz, Cologne-on-the-Rhine, Germany.*—The annexed illustration is a vertical section of a smelting furnace embracing the principle of this invention. The shaft A is carried loosely by the brackets B resting upon the bearers C; under A are two water-cooled annular chambers D and D¹, consisting of several cooling chests, and under these circular coolers is the movable and adjustable hearth E. The annular chambers D and D¹ are adjustably suspended under A by means of the hanging bolts F F¹, carried by B, and the carriers G G¹, which surround D D¹. In connection with the movable hearth E are formed two adjustable annular air entrance passages H H¹. The suction of the gases and the consequent entrance of the atmospheric air through both the

annular air openings H H¹ into the shaft A is effected through the suction pipe I I¹ I² and the steam injector J. In order to remove any non-gaseous portions of the furnace smoke, which is deposited when the smoke comes in contact with the steam of the injector, without interfering with the working, two pipes I¹ I¹ are mounted on a carriage K, which runs on rails, and as soon as a deposit has formed in one of these pipes a clean pipe may be quickly substituted, and the pipe which has been used cleaned. In order as much as possible to prevent the collection of deposit, there is in the upper part of the shaft a depending tube L supported by four ribs M upon the funnel N, and the tube L reaches up to underneath the bell-covering O. The pulverised material is fed in through the damper P into this pipe, and thereby carried below the suction of the furnace, whilst coarser materials and coke reach the shaft of the furnace outside the pipe K through spaces between the hopper N and bell-covering O and by the lifting of the latter. Four claims are made.—No. 14053. September 6th, 1890. 6*d.*

REPAIRING DRAIN PIPES.—*W. Reynor, London.*—The inventor here effects the repairing of drain pipes by the use of the following apparatus. Two pistons are used for this purpose, each piston being composed of an indiarubber disc, which fits the pipe to be repaired, held between two metal plates 5in. in diameter, which plates can be screwed up so as to slightly alter their diameters if required. Each piston has an extending arm of a U-shape. The two pistons are made to slide on a hollow tube about 2in. in diameter and 2ft. 6in. long. When the pistons are closed together in the centre of the tube the ends of the U arms will be at the end of the tube. Two ropes are passed through the tube and fixed to the arms extending beyond the opposite ends thereof, so that by pulling these ropes the pistons will be brought closer together, so compressing the cement, which had previously been placed between them, into any orifice, open joint, or other cause of leakage. Claims: The combination of the different parts as above described, for the staunching and testing of drains, as described.—No. 579. January 13th, 1890. 6*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

AN IMPROVED BORING MACHINE FOR TAPER HOLES.

THE annexed illustration represents a general view of a new boring machine for boring taper holes. It is made by Messrs. James Spencer & Co., Chamber Iron Works, Hollinwood, near Manchester. The frame of the machine is triangular shaped, having slotted holes in the base to enable it to be fitted to the flat surfaces of cylinders, &c., when boring conical valve seatings or machining the flat surfaces round the said seatings. The headstock is adjustable, by means of a screw and hand-wheel, through a range of 12in. in a vertical slot in the main frame, and is provided with a strong cast-iron spindle with adjustable conical bearing on the lower end for adjustment for wear, and a steel tail pin for receiving the end thrust. This spindle derives motion from the driving shaft by means of a worm and worm wheel at its upper end, the steel worm running in an oil trough, and the wheel having a phosphor-bronze rim. On the lower end of the spindle is a slide adjustable transversely by screw and hand wheel to suit the different sizes of holes to be bored. On this slide is carried another oblique slide, which gives the requisite amount of taper to the surface operated upon. The latter slide carries an adjustable tool-holder, which has a self-acting feed motion derived from a star wheel coming in contact at each revolution with a suitable stud. The machine is driven by a three-speed cone pulley, and is suitable for boring holes from 21in. down to 7in. diameter and 12in. deep, and will face flat surfaces up to 2ft. 3in. diameter.

THE INSTITUTION OF CIVIL ENGINEERS.

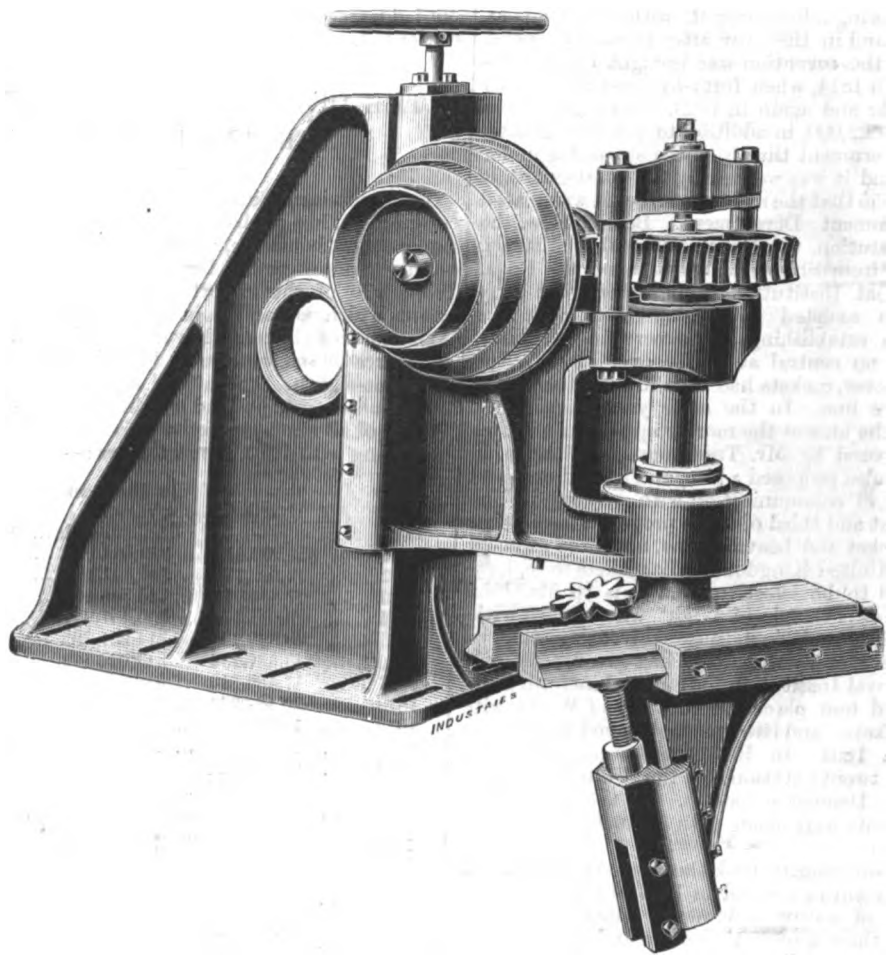
AT a meeting on the 3rd inst., Sir John Coode, K.C.M.G., President, being in the chair, a paper was read on "Electric Mining Machinery," by Messrs. Llewelyn B. and Claude W. Atkinson.

During the last four years the authors had been constantly connected with the application of electricity to mining, and had spent a considerable amount of time underground, both in experimental work and in teaching those who would have charge of the electrical machinery. It was pointed out in what way the conditions of mining work differed from those existing in other industries, and how they had been dealt with, and some of the machinery now actually employed was described. The use of compressed air was then discussed, and the results of experiments were given, showing that the efficiency of this method of transmitting power was 45·8 per cent. for an air pressure of 19lb. per square inch, decreasing to 25·8 per cent. for an air pressure of 40lb. From more recent experiments by Professor Kennedy, F.R.S., M.Inst.C.E., it was found that in practice an efficiency of 31 per cent. might be realised, or 45 per cent. if the air was heated before being passed into the motor. In the case of the electrical transmission of energy, except when distributed into very small units, there was little difficulty in obtaining 50 per cent. of the power expended in the engine, and there were cases in which an efficiency of 75 per cent. had been realised. One of the most important points with regard to the employment of electricity in coal mines was whether a motor would be likely to cause an explosion. It was necessary in the case of a machine which perhaps might have to work for several hours without attention to guard against the possible accumulation of an explosive atmosphere around the brushes. For this purpose the authors had enclosed either the whole armature or the commutator only in a practically air-tight casing, and the method had been successfully applied to a motor of 40 horse-power. The temperature had been kept down to 70° F. above that of the atmosphere by allowing a sufficiently large cooling surface—namely, 2·3 square inches per watt. To meet the objection that if the firedamp should leak into these covers the resulting explosion might be as disastrous as if they did not exist, it was pointed out that that whenever the proportion of marsh gas to air exceeded 3 or 4 per cent., combustion would take place quietly, and the resulting carbonic acid would tend to prevent explosion in the case of further leakage. Moreover, the authors proposed, in special cases, to introduce a constant supply of carbon dioxide from a steel cylinder into the interior of the casing, thus preventing the ingress of an explosive mixture. Similar methods were adopted for enclosing the switches, and sparking was prevented by providing a resistance coil of small self-induction, which was always connected to the ends of the magnetising coil so as to form a path through which the current in the latter might continue even when the main circuit was broken. The switch itself also had a resistance coil connected to the several points with which it made contact, so that, by slowly opening the circuit, sparking was practically done away with. The application of electricity to pumping in mines was then described and illustrated. The use of belts for driving was not recommended, on account of the want of space and the difficulty of keeping them in good condition in dirty and wet situations.

The employment of electric power for actuating coal-cutting machinery was suggested in 1873 by Mr. Henry Wilde, and first practically applied by Mr. F. Mori, in 1887. This had a cutter of the bar type, revolving upon its axis, and was driven by a dynamo having a normal output of 10 horse-power, situated at a distance of about a mile. It was built by Messrs. W. T. Goolden & Co. Their next machine was one in which the armature shaft itself was made to carry the cutter bar. Later developments of these electrical coal cutters were given. The proper form and dimensions of the cutters were then discussed at some length, the authors preferring the bar type to that in which the tools were fixed into the periphery of a disc, not only as being less liable to be held fast by a fall of coal, but as cutting to a much greater depth. The cutter bar ran at the rate of 500 revolutions per minute, and on an average, including stoppages, from 20 to 30 square yards per hour might be cut in fairly hard coal. At Lord St. Oswald's colliery at Nostell, 55 yards were bared to an average depth of 3ft. 8in. in seventy-five minutes. The relative cost of cutting coal in this way and by hand showed a difference in favour of the machine of 1s. 6d. per ton.

An electric boring machine was described, and also an arrangement for driving an Ingersoll percussive rock drill by electricity, as well as a special form of dynamo adapted for use in transmitting power for electric mining work, with a high voltage.

The authors arrived at the following conclusions:—



A. That electric power was destined to become an important factor in mining mechanics, on account of—
  (1) The facility with which it could be used with machines which required to be moved from time to time;
  (2) The great economy in first cost and reduced cost of working, owing to its efficiency being higher than that of compressed air, or any other medium of power transmission;
  (3) The smaller cost of maintaining the cables, as compared with piping, on shifting floors in roadways, &c.

B That the methods described were sufficient to obviate all objections to the use of electric motors in coal mining, whether by excluding inflammable gases or by constructions which would allow of their safe combustion.

C. That the experiments, trials, and practical work, extending over four years, showed that—
  (1) Electrical pumps might be used with advantage and economy for mine draining;
  (2) Electrical coal cutters could replace hand labour, with saving in cost, and increased production of coal;
  (3) Electrical drilling machines were available in place of machinery worked by hand or compressed air.

IMPROVED BORING MACHINE FOR TAPER HOLES.

CONSTRUCTED BY MESSRS. JAMES SPENCER & CO., HOLLINWOOD, NEAR MANCHESTER.

GENERAL VIEW OF MACHINE.

LIFE SAVING APPARATUS.

THE Board of Trade has recently issued an official report relating to life salvage for the year ending 30th June, 1890. The report states that during the year 1889-90, 132 lives were saved by means of life-saving apparatus. In order to stimulate the exertions of the men employed in the service of saving life from shipwreck the Board of Trade give medals in bronze and silver for acts of special gallantry. The lifeboat and the rocket apparatus form the principal means adopted for saving life on the coasts of the United Kingdom. With few exceptions the lifeboats are the property and under the management of the National Lifeboat Institution. The lifeboats at Ramsgate and Fair Isle are now the only lifeboats under the superintendence of the Board of Trade.

The rocket apparatus, on the contrary, are the exclusive property of the Board of Trade. The following is a short account of the history of the apparatus:—The late Captain G. W. Manby, F.R.S., was the inventor of

Digitized by Google

the mortar apparatus, and therefore of the system of the rocket apparatus. The same idea had, however, previously occurred to Sergeant Bell, of the Royal Artillery, who, as early as 1791, devised a plan for throwing a rope on shore by means of a shell from a mortar on board the vessel in distress, or *vice versâ*, and similar experiments were made by a Frenchman named La Fère. Manby, however, had not heard of these inventions, and his own was the first that was used. The idea occurred to him in February, 1807, when present at a shipwreck, and in February of the next year he saved seven persons from a wreck by throwing a line over it, with which a boat was hauled off; and in the year after he saved several crews. In 1810 the invention was brought before Parliament; again in 1814, when forty-five mortar stations were established; and again in 1823, when a grant was made to him of £2,000, in addition to previous grants. Though the Government thus took the apparatus under its protection, and it was worked by the coast-guard, it was not until 1855 that the management of it was placed under a Government Department. Before this the Shipwreck Institution, the Royal National Institution for Saving Life from Shipwreck (now called the Royal National Lifeboat Institution), and other local shipwreck societies assisted and co-operated with the Government in establishing and supervising stations, but there was no central authority over all. In the meantime, however, rockets had been invented and used for carrying the line. In the same year that Manby had conceived the idea of the mortar apparatus a rocket had been proposed by Mr. Trengrouse, of Helston, in Cornwall, who also proposed a kite, and a hand and lead line, as means of communication with a vessel in distress. The first and third of these proposals have borne fruit in the rocket and heaving-cane, now used at every station in the United Kingdom. His rockets were, however, too small to be effective; and it is to Mr. John Dennett, of Newport, Isle of Wight, who worked without any knowledge of Trengrouse's invention, that we owe the first rocket by which life was saved. As early as 1826 the Royal Institution for Saving Life from Shipwreck supplied four places in the Isle of Wight with Dennett's rockets: and life was first saved by them at Bembridge in 1832. In 1853 there were about one hundred and twenty stations in the United Kingdom supplied with Dennett's rockets. In the autumn of 1852 experiments were made with an anchor shot and a grapnel shot.

When the Government took the life-saving apparatus under its own entire control in 1855, there was a large number both of rocket and mortar stations, at about half of which there were both rockets and mortars. The superiority of the rocket apparatus was acknowledged, but experiments were made by Colonel Boxer to improve both means of communication. He succeeded in improving both; the first by a new shot of different shape, and containing fuses, which threw a light over vessels as they passed, and the latter by a new rocket, a combination of two rockets in one case, one being a continuation of the other, so that the first compartment carried the projectile to its full elevation, and the second gave an additional impetus; the range thus obtained was found to much exceed that of two rockets attached side by side to one stick. This rocket was the same in principle as that now used. In 1857 the Board of Trade, who had then taken over from the Customs the management of the apparatus, issued fresh instructions, which adopted almost entirely the proposals made by Commander Ward, R.N., late Inspector of Lifeboats, to the Lifeboat Institution. Commander Ward was also the inventor of the cork life jacket, used universally by the coast-guard, specimens of which were exhibited at the Paris Universal Exhibition of 1855. In the same exhibition there were also shown the "Travelling Life Buoy," or "Sling Life Buoy," now used with the apparatus, which was invented by Commander Kisbee, R.N. The apparatus and the method of working it may be thus shortly described:—A rocket is fired which carries a line over the ship, the crew haul on the rocket line, and this brings anendless rope (called a "whip"), rove through a block with a tail attached to it, which they make fast to a mast or some other portion of the wreck high above the water. Those on shore then haul off to the ship a hawser attached to the whip, which is made fast to the mast or other portion of the wreck about 18in. above the whip. Those on shore then set the hawser up and send up to the ship the sling life buoy. When the buoy reaches the ship one of the shipwrecked persons gets into it, and it is hauled back with its occupant. This process is repeated till all, or as many as possible, are saved. It is sometimes better to use the whip and sling life buoy alone. When the vessel is close to the shore, the heaving cane is used instead of a rocket.

Life-saving stations, supplied with cliff-ladders for descending cliffs for the purpose of saving life, are also established at certain places where the rocket apparatus would be unavailable. A few life stations are also supplied with heaving canes and lines and life buoys only. The Board of Trade issue millboard tablets with instructions to crews of vessels. These tablets are supplied gratuitously to shipowners and masters for placing on their vessels in a conspicuous position, and are also fixed in public places along the coast. Gear is also supplied to all Royal Naval Reserve drill stations and to training ships, and every certificated officer in the mercantile marine is required to understand the working of the apparatus.

On the 30th June, 1890, the number of life-saving stations was 303—viz., rocket apparatus stations, 292; cliff-ladder stations, 7; and heaving line and life buoy stations, 4.

THE DECLINE OF THE AMERICAN MERCANTILE MARINE.

The American Bureau of Statistics, in its last quarterly report, has published some statistics of the American mercantile marine, which show that during the past twenty years there has been a continuous decline in the proportion of the imports and exports of the United States which is carried in American vessels. In 1870 American vessels carried over one-third of the country's commerce by sea, whereas in 1890 the proportion is little over one-eighth. The official figures for aggregate imports and exports by land and in American and foreign vessels of all kinds respectively for the twenty-one years, beginning with 1870, are as follows:—

	Overland.	In American Vessels.	In Foreign Vessels.
1870	——	$352,969,401	$638,927,488
1871	$22,985,510	353,664,172	755,822,576
1872	27,650,770	345,341,101	839,346,362
1873	27,869,978	346,306,592	966,723,651
1874	23,022,540	350,451,994	939,206,106
1875	20,388,235	314,257,792	884,788,517
1876	18,437,154	311,076,171	813,354,987
1877	17,464,810	316,660,281	859,920,536
1878	20,477,364	313,050,906	876,991,129
1879	19,423,685	272,015,692	911,269,232
1880	20,981,393	258,346,577	1,224,265,434
1881	25,452,521	250,586,470	1,269,002,983
1882	34,973,317	227,229,745	1,212,978,769
1883	48,092,893	240,420,500	1,258,506,924
1884	46,714,068	233,699,035	1,127,798,199
1885	45,332,775	194,865,743	1,079,518,566
1886	43,700,350	197,349,503	1,073,911,113
1887	48,951,725	194,356,746	1,165,194,508
1888	54,356,827	190,857,473	1,174,697,321
1889	66,654,378	203,805,108	1,217,063,541
1890	73,576,263	202,451,086	1,371,116,744

and the following tables give the vessels entered and cleared in 1890 from each country in which the tonnage exceeded 200,000:—

Of these, while 3,709,005 tons of foreign steamships cleared for England, while the American steamships aggregated only 41,648 tons, while there were no clearances of American steamers to Germany, the Atlantic ports of France, or the Netherlands—on the other hand, American vessels monopolise the sea-going commerce of the United States with British Columbia, and have a large proportion of that with the maritime provinces of Canada and Cuba.

SAWING MACHINES FOR BEVELLED TIMBER.

Some thirty-five years ago, when the picturesque wooden walls of old England ruled the waves—that is, before the introduction of the present metal monsters for our first line of defence—there were, at the old Woolwich Dockyard, since abolished, several machines for sawing balks of timber into bevelled pieces for ships' work. These consisted of vertical reciprocating saw-frames, driven from below. Each machine was fitted with a skeleton swing-frame, carrying one or more saws capable of lateral adjustment on transverse guides whilst working by means of conveniently placed levers. The log to be converted was advanced to the saw on a travelling drag, to which it was secured by dogs at each end. These dogs were pivoted in such a manner that they could be turned by hand independently of each other within certain degrees of a circle, according to the required sweep and bevel of the work. This was lined out, and men were told off to the swing-frame and each of the quadrant dogs, whose duties were to manipulate these and follow the lines on the timber as it passed through the machine.

Some years later M. Normand, of Havre, introduced several improvements in this class of machinery, whereby its efficiency and producing capacity were considerably increased. He arranged means by which the quadrant dogs between which the timber was held and the swing frame carrying the saw could be worked in conjunction without any manual assistance. This proved of great importance, as not only were the services of the workmen dispensed with, but the work was better done—a result which can be well understood when the difficulty of several men working at one machine, and almost irrespective of one another, is taken into consideration.

Not long after the suitability of the band-saw for cutting heavy timber was shown, ingenious minds turned it to account for the purpose under discussion, to which it seems admirably suited. The best machine of the kind is unquestionably that invented and patented by Messrs. Western & Hamilton in 1873. It may be thus described in brief. The two pulleys for the saw are carried by a rectilinear bar, simple mechanism being provided for adjusting the distance between them to suit the length of the saw, and for compensating for the contraction and expansion of the latter when working. One end of this bar is carried by a pivot in the axial line of the driving pulley, whilst the opposite end is fitted to a block in which it is free to swivel and slide longitudinally. The pivot and the block slide on parallel rods by means of a rack and pinion or a screw. According as the one or the other is so moved, the saw is induced to make a more or less oblique cut in the timber as the latter advances on a table actuated by gearing after the usual manner.

The saw-bar carries two brackets, furnished with circular discs having guide slots for the blade. These discs can be turned so as to give a greater or less degree of twist to the saw at each side of the "stuff" under operation, which has previously been lined out according to the required bevels and curves. The attendant adjusts the saw-bar and pulleys, and at the same time regulates the twist of the saw in such manner that it is made to follow the marking-out lines.

The saw-bar, with pulleys, can be fixed so that the work can be sawn without bevels, as in an ordinary horizontal band-saw machine, or the pulleys may be placed in opposite positions, to cut spiral or helical pieces. The table to which the balk is secured is of the ordinary kind, and not adjusted to various angles, as the saw renders this unnecessary. Several of these machines are working, notably one at Messrs. Samuda's shipyard, Millwall, and give great satisfaction, fulfilling all requirements well and expeditiously.

Mr. Thomas Greenwood obtained a patent in 1861 for a novel and ingenious band-saw machine, one of which was shown at the London Exhibition of 1862 by Messrs. Greenwood & Batley, of Leeds. This machine is now in constant use for cutting curvilinear, bevel, and twisted work. The saw-pulleys are carried by a vertical segmental standard, capable of axial movement on its supports, and a rack is fitted to this standard, into which gears a worm, to give the canting or axial motion. By this means the direction of the cut of the saw is determined, and it can be adjusted to make a vertical or diagonal cut at pleasure. The gearing of the canting motion is self-acting, and comprises a friction disc—for

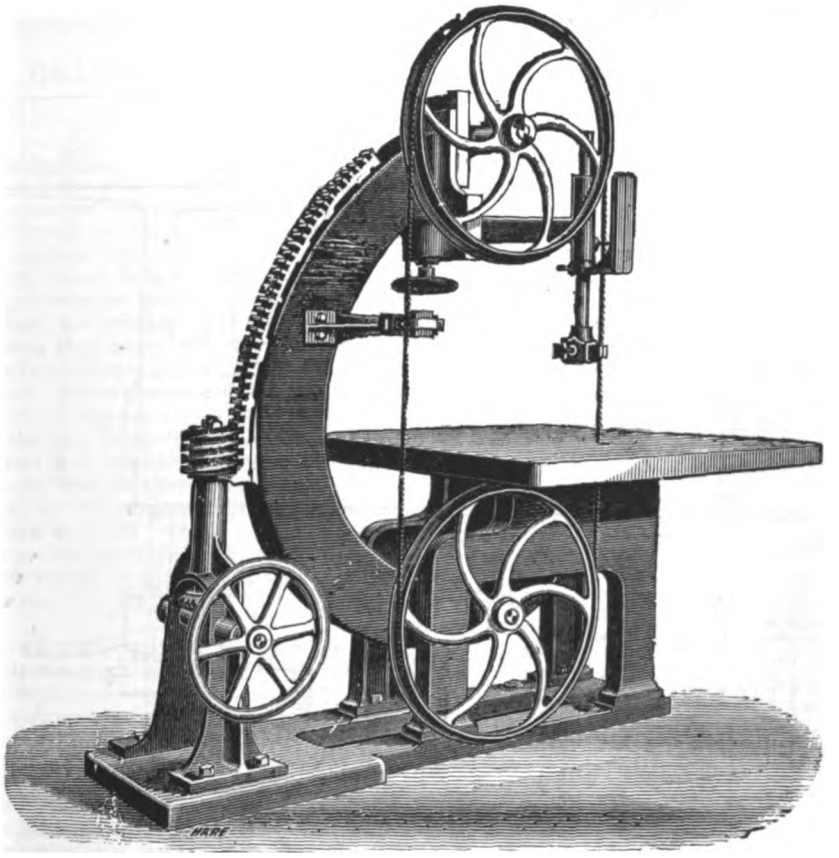

FIG. 1.

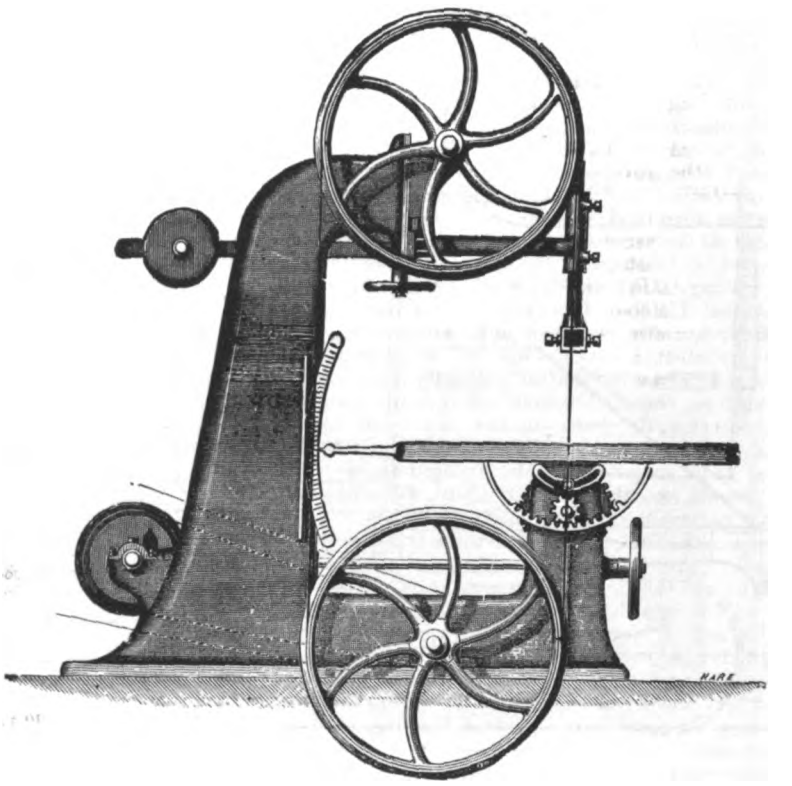

FIG. 2.

varying the rate of motion—and cone pulleys. The inclination of the saw is variable whilst working, a graduated index being provided to show the degree of inclination. The table of the machine is a fixture, and does not cant, as in ordinary machines. This machine has been found highly serviceable for light ships' work, such as bow-ribs and stringers, which have to be sawn in double curvature to suit the bilge of the boat from the keel upwards, and also adapted to the inward curves of the bow. The desired curvatures are marked out in degrees on the stuff at intervals, each degree expressing the successive angle of obliquity. The standard, with saw, is then slowly swivelled on its fulcrum to the successive degrees as the stuff advances. The graduated scale fitted to the machine shows the respective angles of the saw.

The illustration Fig. 1 represents a somewhat similar machine to the one just described, designed by Mr. Samuel W. Worssam, engineer, 7 and 8, Idol Lane, London, E.C., several of which are in operation. The standard carrying the saw pulleys is capable of canting or axial motion, regulated by hand through the medium of a quadrant, worm, bevel gear, and hand-wheel at the back of the standard. An important feature of this machine, and one which, it is claimed, makes it superior to any other, lies in the fact that the centre of radial motion, or axis of the standard, is struck from the surface of the horizontal table at the point where the saw passes through it, and ensures the latter working at any angle through a centre which remains constant, thereby obviating the necessity of altering the saw guides above and beneath the table, or the table itself, each time the angle of the saw is varied, as must be done in another machine we shall hereafter describe.

As in the preceding case, the angle of the standard and saw may be varied while the saw is at rest or while running. In consequence of the constantly changing position of the driving pulleys of the machine, an adjustable counter-shaft or strap-tightening pulleys are necessary for driving it.

In 1878 Mr. Knowling took out a patent for a canting standard band-saw machine differing from either of those just alluded to, in having the standard pivoted on the spindle carrying the lower saw pulley, and the table movable in a horizontal direction instead of being fixed. The principle of this machine is similar to the preceding, but it has a grave defect in that the saw does not pass through the table at a fixed point irrespective of the angle of the table. This defect is not of importance for straight bevelled pieces, which can be lined out at the ends, but it renders the machine useless for cutting varying bevels.

Fig. 2 shows another design of machine for this class of work. Here the table is canted by self-acting motion, and the standard is a fixture. This plan may suit very well for light work, but for heavy work it is not so well adapted, because of the difficulty of holding the balk in position on the table when this is at rest or working at an angle. The machine is constructed after the ordinary manner, as far as the standard, saw pulleys, guides, &c., are concerned, but the table is fitted underneath with a toothed quadrant into which gears a gun-metal pinion, keyed on a spindle carrying a worm-wheel. A spindle or shaft, having at one end a worm gearing into the afore-mentioned wheel, and at the other a bevel wheel in connection with others, and cone pulleys, serves to cant the table. A clutch between the bevel wheels serves to arrest the motion of the table or to angle it in either direction. A scale of degrees is marked on a plate affixed to the standard, and, with a pointer or index finger on the table, indicates the position and swivelling course of the latter.

Double canting-standard band-saw machines have been designed for sawing the bevel edges of cask staves, but are not now in use. This work can be done with less expense by other methods. As we have before remarked, there is practically no end to the adaptability of the band-saw. For nearly half a century after its invention this interesting cutting instrument lay practically useless, whilst at present it is invaluable, not alone for light wood sawing, for which it was in the first place intended, but for the conversion of large balks of timber, straight and bevelled, for sawing metal, and with a knife edge blade for cutting cloth, linen, leather, paper, skins, and other materials.

GERMAN IMPRESSIONS OF AMERICAN IRON AND STEEL INDUSTRIES.

THE Iron and Steel Institute on its recent American trip was, it will be remembered, accompanied by 140 representatives of the Society of German Ironmasters. It is interesting, therefore, to note that at the general meeting of this Society at Düsseldorf a complete record of the excursion was laid before the members who were not fortunate enough to be able to take part in it. The reports were entrusted to various members, a general introductory narrative of the trip being furnished by Mr. A. Thielen, who acted in America as President of the Society. The report on American blast furnace practice was written by Messrs. J. Schlink and A. Schilling, and that on rolling mills by Mr. A. Spannagel. The remaining reports were postponed until the next meeting. The list includes reports on the Northern excursion, by Mr. H. Brauns; on steel manufacture, by Mr. R. N. Daelen; on metallurgical machinery, by Mr. E. Klein; on foundry practice, by Mr. Haedicke; and on railway practice, by Mr. Macco. The meeting excited considerable interest, and was attended by some 600 members.

In the introductory address, Mr. Thielen gave an interesting account of the whole excursion. When the party divided at Chicago forty-five of the German visitors selected the Northern trip, and sixty the Southern. Mr. Thielen selected the latter. The impression the iron industry of the South made upon him was very variable. In some places he saw the very latest improvements; in others, however, he saw nothing but antiquated practice, frequently with the evident object of earning money as rapidly as possible with the least expenditure of capital. Financially the industry is not nearly in such firm hands as that of the North. Indeed, there can be little doubt that many of the mines and works are still in the hands of speculators ready to sell at any moment. The cost of production of the iron ore is 2s. per ton. Coal, usually of good smelting quality, is obtained quite as cheaply. There is an abundant supply of negro labour, and the climate is apparently not unhealthy. It is thus evident that the cost of production of pig iron cannot exceed 26s. to 51s. 6d. per ton. The pig iron contains 2 to 3 per cent. of silicon and 0·4 to 0·6 per cent. of phosphorus, and is now used almost exclusively for foundry purposes. There is no doubt, however, that with proper application of modern processes, steel of good quality might be made.

In his report on the production of pig iron in the Northern States, Mr. Schlink began by pointing out the rapid growth of the American iron trade. The production of pig iron in the United States in 1889 amounted to 7,725,755 tons, compared with 8,377,261 tons in the United Kingdom and 4,525,000 tons in Germany. He then discussed the sources of iron ore supply, and described some of the leading iron works. The enormous daily output of 335 tons from one furnace, as obtained at Carnegie's works, is, he points out, the exception and not the rule. In 1889 there were in the United States 169 furnaces, using coke, in blast, the average daily output being 101 tons, whilst that of the anthracite furnaces and of the charcoal furnaces were 58 and 28 tons respectively. These are figures that need cause no anxiety. All the large American works are intended for the production of rails. It would be

THE "MOGUL" LOCOMOTIVE.

CONSTRUCTED BY MESSRS. BURNHAM, PARRY, WILLIAMS & CO., BALDWIN LOCOMOTIVE WORKS, PHILADELPHIA, U.S.A., FOR THE JAPANESE GOVERNMENT RAILWAYS.

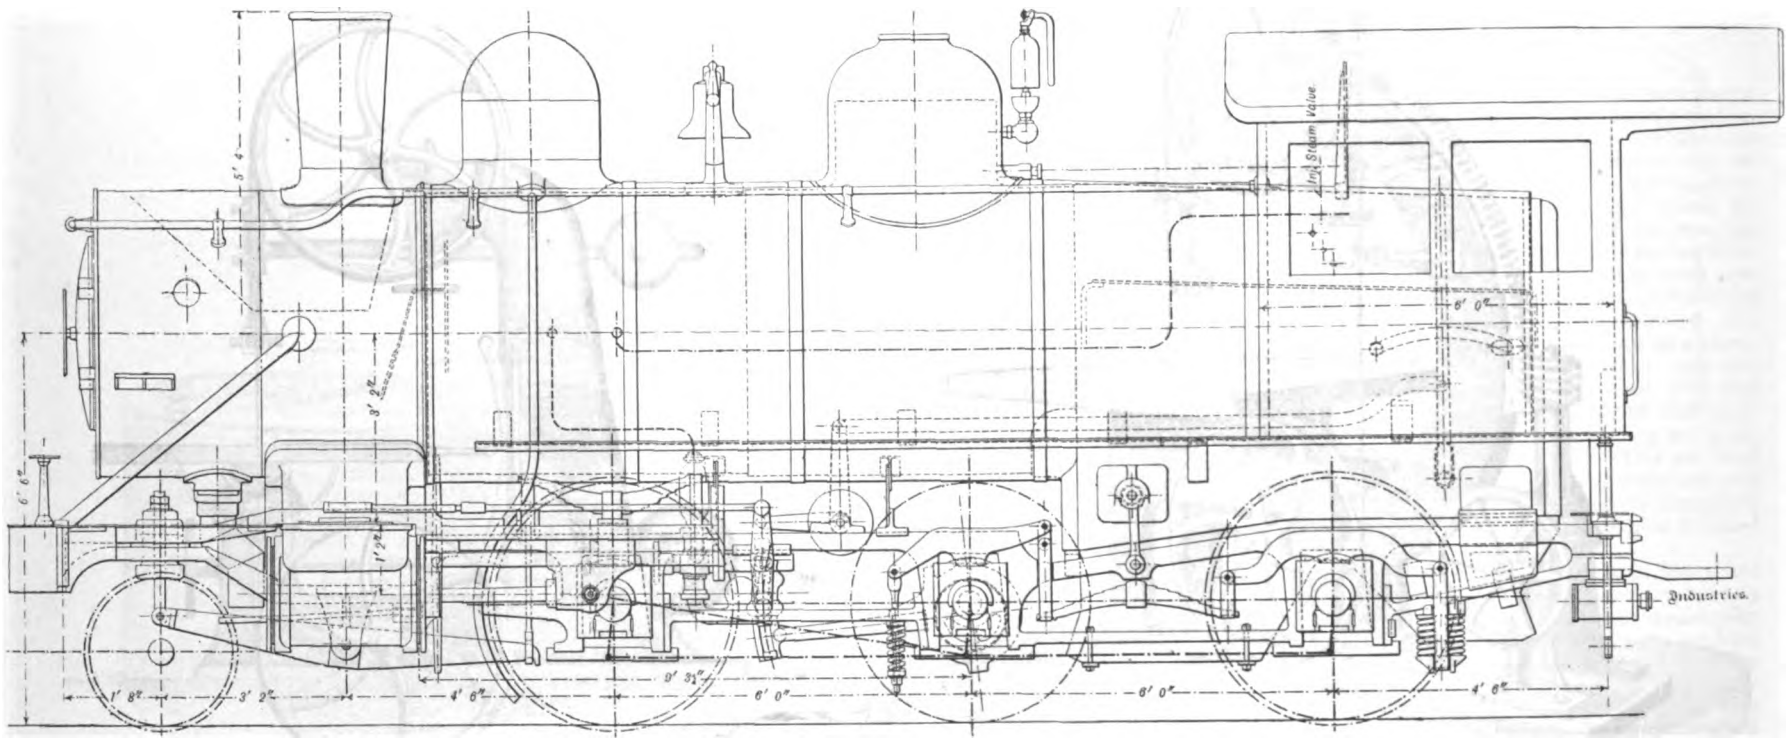

FIG. 1.—SIDE ELEVATION OF ENGINE.

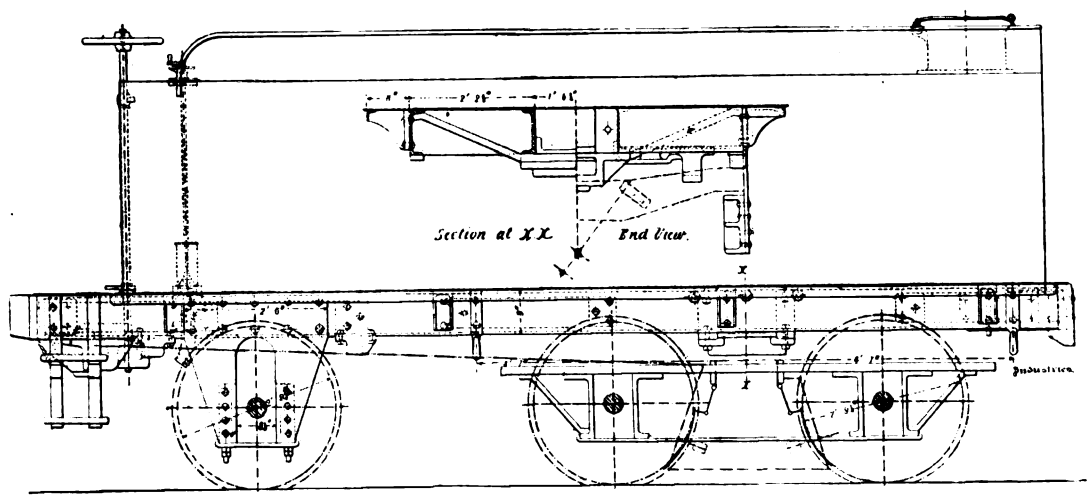

FIG. 2.—SIDE ELEVATION OF TENDER.

impossible to adopt American practice in German works, as the pure ores are wanting, and there would be not sufficient demand for the rails produced. The Lake Superior ores, it will be remembered, contain 6 to 8 per cent. more iron than the Spanish "campanil," now unfortunately unavailable. In conclusion, Mr. Schlink points out that the daily wages of furnace-men at the South Chicago Works average 8s. 8½d. The wages, with a furnace producing 175 tons daily, amount to 4s. 5d. per ton of pig iron, whilst with smaller furnaces they increase to 6s. and more.

In his report on the iron industry of the South, Mr. Schilling pointed out that it was not so highly developed as that of the North, coke blast furnaces having been in operation for not more than twelve years. At Birmingham, in Alabama, the centre of the industry, iron ores, coal, and limestone occur in close proximity. The ores smelted are partly red hematites (red iron ore and Clinton ore) and partly limonites. The former are of chief importance. They occur in Silurian limestone, and have the following percentage composition :—

	Soft Ore.		Hard Ore.
Silica	15 to 18	.....	8
Alumina	3	.....	5
Lime	1	.....	28
Phosphorus.....	0·26 to 0·9	.....	0·2 to 0·8
Iron.....	48 to 52	.....	40

The ore is mined by contract, 1s. to 1s. 8d. being paid per ton for soft ore, and 1s. 8d. to 2s. 6d. for hard ore. The brown iron ore contains so much admixed clay that it has to be washed. It then contains 46 to 52 per cent. of iron. The coal of the Warrior Coalfield is 6ft. to 14ft. thick, and the coke obtained from it contains a considerable quantity of ash. The operatives at the mines and works are almost exclusively negroes, who are found to be unintelligent and difficult to deal with, as they will not work except to obtain the bare necessities of life. The wages are 4s. to 6s. per day. In conclusion, the various blast furnaces throughout the region are described, and the rapid development of the iron industry pointed out. In 1878 the first coke blast furnace was built. Now Alabama produces 780,000 tons of pig iron, of which quantity the Birmingham district yields 75 per cent.

In his report on the American rolling mills, Mr. Spannagel gave a lengthy account of the various works visited. The enormous advantages presented by natural gas in the Pittsburgh district were pointed out. The gas is paid for, in the case of puddling furnaces, at the rate of 6s. per ton of iron produced, and, in the case of boilers at the rate of £10 to £20 per month. At the Philadelphia works at Pittsburgh the consumption of gas amounts to 182,400,000 cubic feet daily, the quantity of coal thus replaced amounting to 10,000 tons. In conclusion, Mr. Spannagel discusses the rolling of tubes in the United States. As it was not permitted to visit these works, his data are based on observations made by Mr. Bendix Meyer, Director of Huldschinsky's Tube Works at Gleiwitz. The American works, he considers, are in advance of the European ones in many points, notably in the amount they produce. He estimates the daily production of the chief works to be as follows:—

	Tons.
National Tube Works	500
Pennsylvania ,, ...	250
M. Clean ,, ...	200
Pittsburgh ,, ...	200
Reading ,, ...	200
Total	1,350

This total is exclusively gas and oil pipes, and is about five times as great as the production of all the German works. Whereas in Germany the lap-welded pipes are usually sent three times through the rolls, in America it is found sufficient to weld the pipe in one heat, and then to pass it for calibration through rolls placed at the side.

An interesting discussion followed the reading of these reports. Dr. Wedding described various methods of transporting and loading material, notably at South Chicago Works, where ore has to be transported from the ship to the works in sufficient quantity to yield 1,600 tons of pig iron daily. The plant employed for this purpose was constructed by the Brown Hoisting Company, of Cleveland, Ohio. The greater portion of the discussion that followed related to the comparative cost of labour in Germany and America.

AN AMERICAN LOCOMOTIVE FOR THE JAPANESE GOVERNMENT RAILWAYS.

WE give above and on pages 149 and 156 illustrations and particulars of a "Mogul" locomotive, constructed by Messrs. Burnham, Parry, Williams, & Co., of the Baldwin Locomotive Works, Philadelphia, U.S.A., for the Japanese Government Railways. Fig. 5 (see page 156) represents a general view of the engine and tender; Figs. 1, 2, 3, and 4 represent a side elevation of the engine, a similar view of the tender, an end view partly in section of the driver's cab, and a section of the locomotive respectively. It will be observed from the illustrations that the engine has three pairs of driving wheels coupled—an arrangement found necessary to give the engine the requisite tractive force, as the engine has to run over a moun-

Digitized by Google

tainous country—and in front a two-wheeled bogie truck with swinging bolster and radius bar. The engine has two cylinders, 18in. diameter, with a stroke of 22in.; the diameter of the driving-wheels is 48in., and the total wheel base 19ft. 6in. The smoke-box is of the extended pattern, and is provided with netting, deflecting plate, and spark ejector. The cylinders are placed outside, and are fitted with cast-iron pistons, having brass rings.

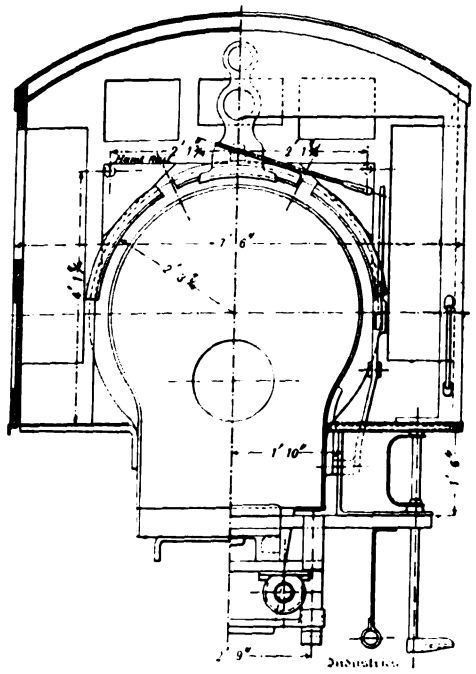

FIG. 3.

The piston rods are of steel, and are keyed to crossheads of the same material. A shifting link motion, adjusted to cut off the steam equally through a wide range of the stroke, and balanced slide valves, are provided. The tender at its fore end runs on a pair of wheels 33¼in. diameter, and at its rear end is supported by a four-wheeled centre-bearing truck, with square forged wrought-iron frames. A tank constructed of channel iron, and having a capacity of 2,600 gallons, is carried by the tender.

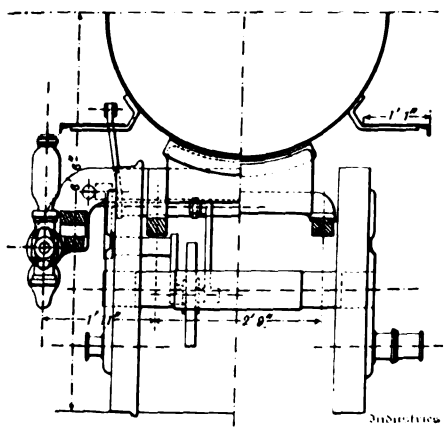

FIG. 4.

One of these engines has recently undergone a series of severe tests in Japan over the hilly country between Gotembo and Numadzu, a distance of fifteen miles, in which there is a total rise of 1,500ft., with gradients varying from 1 in 60 to 1 in 40. This journey, we are informed, was accomplished at the rate of eight miles per hour, under the supervision of Mr. F. H. Trevithick, locomotive superintendent. The leading particulars of the engine we illustrate are given in the accompanying table:—

LEADING PARTICULARS.

	Ft.	In.
Cylinders—		
Diameter of cylinders	1	6
Stroke of pistons	1	10
Length of steam ports	0	16
Width " "	0	1¼
Length of exhaust ports	0	16
Width " "	0	2¼

Capacity of tank on tender, 2,600 gallons.

NAPHTHA ENGINE FOR PUMPING PURPOSES.

CONSTRUCTED BY THE GAS ENGINE AND POWER COMPANY, NEW YORK, U.S.A.

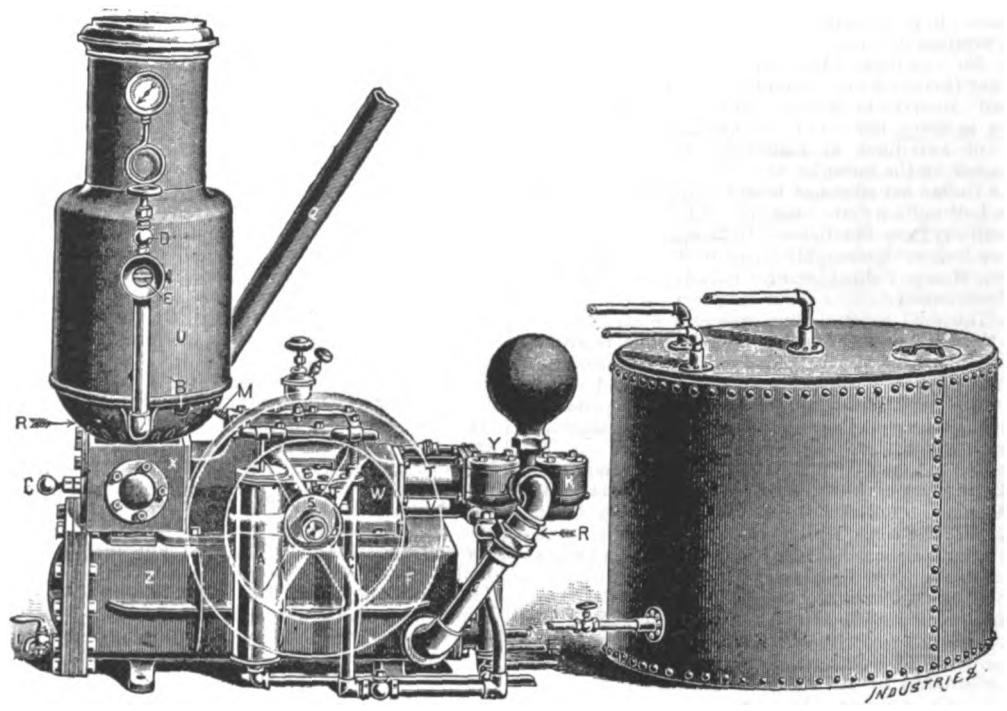

FIG. 1.

NAPHTHA ENGINE FOR PUMPING PURPOSES.

THE above illustrations, Figs. 1 and 2, represent a general view and part sectional view of a two horse-power naphtha pumping engine, capable of pumping 1,000 gallons of water per hour, constructed by the Gas Engine and Power Company, of Morris Heights, New York. The operation of the engine is as follows:—To start the engine the naphtha gas is first forced by the air-pump A (Fig. 1) from the tank to the gas burner M, when it is ignited at the hole B in the base. After the retort U has been heated, liquid naphtha is drawn by the hand-pump C from the tank, and forced into the retort at the inlet R, and converted into gas under pressure. The injector valve D is then opened, delivering gas to the base burner B, and the pump started, the intensity of the flame being regulated by the damper E. The further action of the engine is automatic, as the naphtha pump V forces a continuous supply of naphtha to the retort, which drives the expanded gas to the pressure cylinder

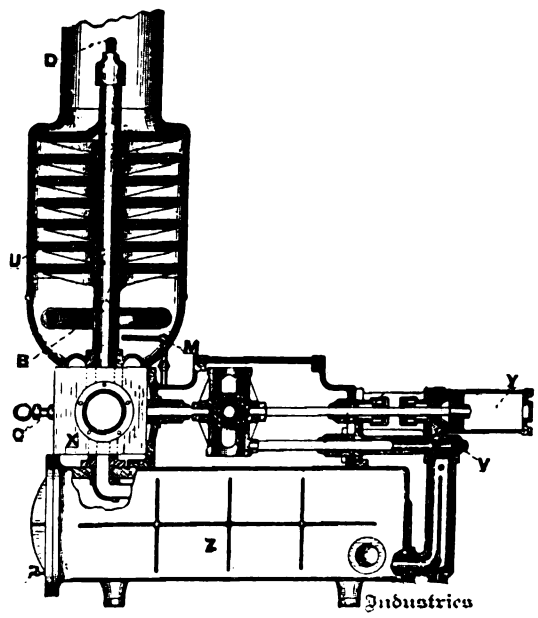

FIG. 2.

X, driving the piston and its attachments, and is then exhausted into the condenser Z to be condensed, after which it is again taken up by the pump V and forced to the retort U. As its volume is being constantly diminished by the amount used in the burner B, a second feed pipe or "make-up" is attached to the pump V, and supplies this constant loss. The water-pump Y is of the ordinary double-acting type, and needs no explanation. We are indebted for our illustrations to our American contemporary, the *Iron Age*.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 10th February, 1891.

Iron.—There has been no change worthy of note in the general state of the iron market during the past week. The outlook continues good, especially as regards the building industry, but the demand has not yet made itself felt, and prices remain the same as those of the previous week. In one or two instances business has been transacted at the exceptionally low prices of 125s. a ton for bars and 133s. a ton for joists. Reports from the provinces show a tendency to greater firmness in general without any advance in prices. The price for castings—112s. 6d. per ton—remains unchanged, but there is a fair amount of activity in the Haute Marne and Meurthe-et-Moselle districts. The Conseil Général de la Seine has voted a concession for the construction of two lines of tramways, with mechanical tractive power, in the suburbs of Paris. The administration of the Indian colonies has been empowered to borrow two and a half million francs towards the construction of a line of railway from Pondicherry to Tirupapaluir. A contract for an iron bridge weighing over 10,000 tons has been secured by Messrs. Schneider, of Creusot, from the Roumanian Government.

Coal.—The coal market continues very firm. Reports from the Northern and Central mining districts testify to a great amount of activity, and even to the opening of new shafts. It is with difficulty that the demand can be supplied even now that the waterways are re-opened for traffic, since consumers in general are anxious to replenish their stocks, which were almost exhausted.

Copper, Tin, Lead, and Zinc.—The copper market is very dull and prices have fallen since last week. Best Chilian bars are quoted £57*s* 5*s*., and ordinary Chilian bars at £55 5s. the ton. Tin has fallen; Billiton is quoted at £96 10s., and Banca £98 10s. the ton. The lead market remains stationary, and, although there is little doing in zinc, quotations continue to hold firm.

Cupolas for Frontier Defence.—The Belgian Government has given an order to Messrs. Schneider, of Creusot, for two cupolas for frontier defence. This makes a total of twelve ordered by the same Government from Messrs. Schneider. The order for these two last was not confirmed until the results of the trials of the cupolas furnished by other firms in France and Germany had testified to the superiority of the Creusot type.

The Short Time Question.—A report has been handed into the Chamber of Deputies of a census taken of workmen in the Department of the Seine in order to ascertain their individual views with regard to the legal control of the hours of labour, and as to what number of hours should constitute the working day. Out of a total of 21,394 there were 5,419 for the eight hours system without any overtime; 1,513 were for eight hours with overtime, 1,247 for the day of nine hours, 7,010 for ten hours, and 429 for eleven hours and over. Of the above over 72 per cent. were for a legally limited working day.

BERLIN, 9th February, 1891.

Prize Essays on the Removal of the Smoke Nuisance.—In order to ascertain the present state of our knowledge with reference to appliances for the abatement of the smoke nuisance, the Association of German Engineers (*Verein Deutscher Ingenieure*), Potsdammerstr. 131, Berlin, W., has offered 8,000 marks in prizes for two essays. The subject of the first essay, which is to be sent in before December 1st, 1892, is "The Appliances Employed in Steam Boilers for the Attainment of a Smokeless Consumption of Fuel." The subject of the second essay, which is to be sent in before December 31st, 1894, is "The Appliances which have been hitherto employed, both for household and business purposes, for the Attainment of Smokeless Consumption." The writer of the second essay is to deal with the subject of appliances for steam boilers only in so far as it immediately concerns his own subject. Each essay must contain, besides a short examination of appliances used in the past, a thorough criticism of those now in vogue in the countries dealt with. Especial importance will be attached to an exact statement of the amount of success which has attended regulations made in the various countries, districts, and towns for the abatement of the smoke nuisance. The appliances described in the essay are to be illustrated by drawings, and the committee of judges are empowered to offer 1,000 marks for the drawings in addition to 3,000 marks for each of the two essays. The competition for either of the prize essays is not restricted by nationality. Committees of experts have been appointed to make the awards for each of the prize essays.

Strikes in Germany.—From a recent Government report we learn that, in the period from January 1st, 1889, to April, 1890, no less than 1,131 strikes took place in the German Empire, affecting 394,440 men. As regards the results of the strikes, the men obtained their entire demands in 187 cases, and partly so in 468 cases, while in 420 cases they were entirely unsuccessful. As to the remainder, details had not been obtained in time to include them in the report. As regards the different branches of industry affected by the strikes, mining claims about 48 per cent. of the strikes, which is followed by the building trade with 18 per cent., the textile industry with 12 per cent., the iron trade with 4 per cent., and miscellaneous with 17 per cent.

Electric Lighting at Lockstedt.—The Common Council of Lockstedt, near Altona, which has over 2,000 inhabitants, has decided to introduce a system of electric lighting in the streets of the town. The carrying out of the installation has been entrusted to the Thomson-Houston International Electric Company of Hamburg.

Shipbuilding in Germany.—During the past year were built in the shipyards in Stettin 238 ships, with 18,400 registered tons gross tonnage. At the beginning of this year twenty-three ships were in the course of construction, among them a double-screw fast steamer of 11,600 tons displacement for the Hamburg-American Mail Company, and two armour-plated corvettes of each 1,000 tons for the Imperial Navy, which are being built by the "Vulcan" Company.

VIENNA, 9th February, 1891.

The Iron Market.—The condition of the iron market remains unchanged. In the Bohemian market there was a tendency towards better prices, in consequence of an increased demand for iron for agricultural purposes, and large quantities have been taken from the market. There is a brisk demand for axles, and prices tend to increase. Foundry goods have a lessened sale, but prices remain unchanged. The prices of wire and wire nails are to be raised shortly by the Bohemian Syndicate. A discussion between Austrian and German manufacturers with regard to their respective spheres of trade has been followed by the export of German iron into Bohemia, the prices, including customs duties, being lower than those of the syndicate. Sheets, both black and tinned, have a good sale, and prices are firm. In Hungary the situation is improving, especially as regards refined iron. Consumers expect an important decrease in the price of pig iron, and are at present unwilling to buy. The present price of pig iron in Hungary is 5·75fl. per 100 kgrs. Prices at Vienna for best qualities are:—Bar iron, 13fl.; black sheets, 16fl.; boiler plates, 19fl.; tinned plates, 32fl.; and sleepers, 12·5fl. per 100 kgrs. The price of Titna pig iron is, for home products from 46fl. to 59fl. per ton, Scotch Coltness (in Vienna) 72fl., and English Clarence 62fl., ingots, 92fl. per ton.—The recent negotiations between the Austrian and German manufacturers were caused through the expiry of an agreement, which lasted up to the end of last year, that German rolling mills should not traffic with Austria nor Austrian rolling mills with Germany. This agreement has not been renewed, and the market for German rolling mills has been considerably widened. Both from the Ruhr and from Bohemia it is announced that the traffic of the Rhine district and Westphalia with Bohemia has become much more active.

The Coal Market.—The active market and the difficulties of traffic encouraged the Silesian coal mines to raise their prices. Although these difficulties have now been overcome, prices are well maintained, since the demand for coal, both for industrial and for household purposes, shows a tendency to increase.

Designs for New Railway Station.—The Warsaw-Vienna Railway Company, at Warsaw, Russia, has offered prizes for competitive designs for a new station at that city. There are to be prizes of 3,000, 2,000, and 1,000 roubles for the best three designs respectively, and three additional prizes of 500 roubles each for three designs next in the order of merit. Detailed information can be obtained by addressing the company at Warsaw.

DÜSSELDORF, 10th February, 1891.

The Iron Market.—Prices of pig iron remain unaltered. There was a brisk demand for spiegel iron, and for wrought iron there was an active inquiry. For rolled rods there is no great alteration in the market, and the business in both coarse and fine sheet iron was also quiet. The stock of foundry pigs at the end of December, 1890, was 23,736 tons. The prices of iron are—For 10–12 per cent. spiegel, 58-60 marks; pig iron, No. 1, 75 marks; No. 3, 63 marks; Thomas pig, 49 marks; and Bessemer, 75 marks; wrought iron, 170 marks.

The Coal Market.—The want of waggons which was reported last week continually increases, and great discontent is expressed with Mr. Maybach, the traffic manager.

Transportation Difficulties.—Although the ice on the Rhine has fortunately disappeared without causing any material damage, the injury done to trade and traffic is by no means at an end. The blast furnaces have no raw material, and one in the possession of Messrs. Krupp, at Duisburg, has been blown out for want of ore. A similar consequence is feared at the works of the Vulcan Company Limited.

Accidents.—The accident at the Hibernia mine has now claimed fifty-three victims. This is the third accident which has occurred at the same seam within the last few years. At the works of the Bochumer-Verein a ladle has been upset, and eight workmen were more or less severely wounded.

General Engineering.—The well-known Humboldt machine-making company is about to add to their establishment a new department for the construction of electrical machines.

Steam Boilers and Engines in Prussia.—The official record gives the following figures relating to steam boilers and engines in Prussia:—

	1889.		1890.
Stationary boilers	47,151	...	48,538
Stationary engines	45,192	...	46,554
Portable boilers and engines	12,177	...	12,822
Marine boilers	1,836	...	2,046
Marine engines	1,674	...	2,007

The boilers and engines of the imperial marine and locomotive engines are not included. The important increase in the number of the marine engines is to be attributed to an alteration in the manner of recording.

Electric Transmission of Power.—The Oërlikon Machine Works have acquired at the village of Hochfelden, in the Glatt valley, water power which will be sufficient for driving two turbines, each of from 200 h.p. to 300 h.p. Electricity will be generated at Hochfelden, the pressure being 25,000 volts, and transmitted to Oërlikon, a distance of twelve miles, by means of overhead wires supported on 40ft. poles, alongside the railway and the country roads. There will be four cables, each 4 mm. in diameter, of which one will serve as a reserve. At the works the pressure will be reduced to 50 volts, and the power will be utilised for driving the whole of the machine tools in the establishment.

AMSTERDAM, 9th February, 1891.
